DEFFAND, Marie (de Vichy-Chamrond), marquise du, an accomplished French woman, born in 1697, died in Paris, Sept. 24, 1780. She was of noble birth, and was educated in a convent, but at an early age astonished her parents by her sceptical opinions on religious subjects. At 20 years of age she was married to the marquis du Deffand, from whom her indiscretions soon caused her to be separated, after which she launched into a career of fashionable dissipation, and for many years was one of the most brilliant ornaments of the court of the regent and of Louis XV. Although incapable, from a natural selfishness and want of sympathy, of entertaining the passion of love, she knew how to inspire it in others; and over the greater part of her numerous lovers, among whom, it is said, was the regent himself, her influence remained unimpaired until their dotage. Her conversational powers and clear, cool judgment caused her to be courted by the most eminent men of the time, and when in her 56th year she became totally blind, her saloons in the convent of St. Joseph's were the favorite resort of Montesquieu, Voltaire, President Hénault, David Hume, D'Alembert, and many others. At this period of her life she became acquainted with Horace Walpole, between whom and herself a correspondence was for many years carried on. As she grew old her selfish traits developed more disagreeably, and the ungenerous manner in which she treated her companion and reader, Mademoiselle de Lespinasse, alienated many of her friends. Her latter years were marked by peevishness and *ennui*, and she died unhappy after several unavailing efforts to consecrate herself to the life of a devotee. Her epistolary writings comprise her correspondence with Hénault, Montesquieu, D'Alembert, and the duchess of Maine, and with Horace Walpole, the latter being compiled from the original letters deposited at Strawberry Hill. Her style is a model of elegance.

DEFIANCE, a N. W. co. of Ohio, bordering on Ind.; area, 414 sq. m.; pop. in 1850, 6,966. The St. Joseph's and Maumee are the principal rivers. The surface is level, the soil good, and

timber very abundant. In 1850 the productions were 90,691 bushels of corn, 47,806 of wheat, 26,471 of oats, 2,372 tons of hay, and 19,241 bushels of potatoes. There were 6 churches, 2 newspaper offices, and 1,220 pupils attending public schools.—The capital, DEFIANCE, a flourishing village and township, pop. in 1853, about 1,000, is agreeably situated at the junction of Auglaize and Maumee rivers, and at high water is accessible by steamboat. A fort, called by the same name as the town, was built here by Gen. Wayne in 1794. The place was then occupied by a large tribe of Indians, who owned extensive corn fields and orchards.

DEFLAGRATION (Lat. *deflagro*, to burn), the sudden combustion which takes place when an inflammable substance, like sulphur or charcoal, is mixed with nitrate or chlorate of potash and projected into a red-hot crucible. The instantaneous decomposition of the salt, and the uniting of its oxygen with the combustible body, give rise to the explosion which is called deflagration.

DEFLECTION. See DIFFRACTION.

DEFOE, DANIEL, an English novelist and political writer, born in London in 1661, died in the same city, April 24, 1731. The son of James Foe, a butcher and dissenter of the parish of St. Giles, Cripplegate, he was admitted by right of his birth to the freedom of the city in 1688, under the name of Daniel Foe, but afterward assumed the prefix De, as one of his enemies asserted, to escape the reputation of an English origin. He was educated at a dissenting academy at Newington Green, near London; was strongly impressed both by his parents and teachers with religious sentiments and principles; and, after leaving the academy in 1680, was nominated a Presbyterian minister. It was his disaster, however, as he expresses it, "first to be set apart for, and then to be set apart from, that sacred employ;" and he became interested in politics more than divinity. There is attributed to him a pamphlet published in 1682, entitled "Speculum Crape-Gownorum; or, a Looking-Glass for the Young Academics," which was a lampoon on prevalent high-church notions, and an answer to Sir Roger L'Estrange's "Guide to the Inferior Clergy." In 1683, while war existed between the Austrians and Ottomans, he issued his "Treatise against the Turks," combating the general sentiment in favor of the latter, and arguing that it was "better that the popish house of Austria should ruin the Protestants in Hungary, than that the infidel house of Ottoman should ruin both Protestants and Papists." In 1685 his zeal for the Protestant succession led him to join the standard of the unfortunate duke of Monmouth; but unlike many of his associates, he escaped both the hazards of the field and the sanguinary campaign of Judge Jeffreys, which succeeded the suppression of the rebellion. He repaired to London, engaged in trade as a hose factor in Cornhill, published in 1687 a tract assailing the proclamation of King James for the repeal of the penal laws, hailed the revolution of 1688 as the salvation of Protestantism, was one of the superbly mounted escort of volunteers who attended William and Mary from Whitehall to the mansion house, Oct. 29, 1689, and in 1692 was declared bankrupt and was obliged to abscond, but succeeded in making a composition with his creditors, they accepting his personal bonds, which by unwearied diligence he punctually paid. Subsequently he discharged his full liabilities to such of his creditors as had themselves fallen into distress. In 1694 his friends arranged a mercantile enterprise for him at Cadiz, but he declined it, "Providence," as he remarks, "which had other work for him to do, having placed a secret aversion in his mind to quitting England." In the next year he was appointed without solicitation accountant to the commissioners of the glass duties, in which service he continued till the suppression of the tax in 1699. The many inventions of that period and his own numerous schemes suggested to him the "Essay on Projects" (1697), the perusal of which quickened the mental energies of Franklin, and which has been said to contain the ideas of the French revolution without its follies. He published a variety of political pamphlets during several years, the most successful of which was the "True-born Englishman" (1699), a poetical satire commencing with the well-known couplet:

> Wherever God erects a house of prayer,
> The devil always builds a chapel there.

It was designed to vindicate King William from the odium of foreign birth, had an almost unexampled sale, and obtained for the author direct personal intercourse with the king. In 1701, when the bearers of the famous Kentish petition were imprisoned by order of the house of commons, Defoe composed and presented a threatening remonstrance, signed "Legion," claiming to be sent by 200,000 Englishmen, which produced immense commotion, deterring for a time several of the members from attending the house. Two other tracts speedily followed, in one of which he maintained the original rights of the collective body of the people, and in the other declared the reasons against a war with France. The latter is one of the ablest tracts in the language, and though it was adverse to the favorite policy of William, it did not excite his displeasure; he was till his death the patron and friend of Defoe, who vindicated his character and memory as well as many of his measures. In 1702 he published the "Shortest Way with Dissenters," in which, with exquisite irony, he assumed the tone of a high churchman, and gravely proposed to establish the church and rid the land of dissenters by hanging their ministers and banishing their people. His satires had already mortified and offended many of the tory leaders, through whose influence his pamphlet was now voted a libel on the house of commons and was ordered to be burned by the common hangman. The proclamation issued

for his arrest furnishes our best knowledge of his personal appearance, describing him as "a middle-sized, spare man, about 40 years old, of a brown complexion, and dark brown colored hair, but wears a wig; a hooked nose, sharp chin, gray eyes, and a large mole near his mouth." He was at this time owner of some brick and pantile works near Tilbury fort, from which he absconded; but he gave himself up when a prosecution was begun against his publisher, and was condemned to be fined, pilloried, and imprisoned. He wrote a hymn to the pillory, pronouncing it

> A hieroglyphic state machine,
> Condemned to punish fancy in;

and during his 2 years' imprisonment at Newgate began a periodical paper, entitled the "Review," published twice a week, which was continued till 1713, and was the forerunner of those popular miscellanies which were soon made attractive by the wit and taste of Addison and Steele. His enfranchisement was due to the solicitation of Harley, afterward earl of Orford. Though occasionally employed in the service of the queen, and once upon a secret mission in a foreign country, he continued his literary labors, and published in 1705 the "Consolidator," or memoirs of transactions in the moon, in which he developed a lunar language, and made the lunar politicians discuss the wars of Charles XII. of Sweden; in 1706, the satire of *Jure Divino*, in which he attacked the doctrines of passive obedience and divine right; and also several excellent treatises relating to the union with Scotland, which he was efficient in promoting, being sent by the cabinet of Queen Anne on a special important mission to Edinburgh; in 1709, a "History of the Union," which is the most authentic on the subject; and from 1711 to 1713, a series of pamphlets against the insinuations of the Jacobites and the schemes of the pretender. The irony of some of these was misapprehended, and he was again fined and for a short time committed to Newgate, July 29, 1712, where he finished his "Review," which thus had both its beginning and end in prison. After the death of the queen, his enemies assailed him from every quarter, so overwhelming him with the "rage of men," that in 1715 he published a general defence of his conduct under the title of an "Appeal to Honor and Justice." He had hardly finished this when he was struck with apoplexy, the result of anxiety and despondence, and after languishing for 6 weeks recovered. He now determined to abandon political satire, and write works for the promotion of religion and virtue. Such were his "Family Instructor" (1715) and "Religious Courtship" (1722). In 1719 appeared the "Life and surprising Adventures of Robinson Crusoe," the most popular of novels, which has uniformly been a favorite of the young and old, learned and unlearned, which was to constitute the library of Rousseau's Émile, or perfectly educated young man, which was one of the three books that Dr. Johnson wished had been longer, and which by universal admission is as moral as it is charming. The prototype of Crusoe was Alexander Selkirk, a brief narrative of whose adventures on the desert isle of Juan Fernandez had been published in 1712; and the hint thus given, according with the injured feelings and lonely contemplations of the unprosperous man of genius, was elaborated by him into a complete and delightful romance. It was followed by a series of remarkably ingenious fictions, as the "Life and Piracies of Captain Singleton" (1720), the "Fortunes and Misfortunes of Moll Flanders" (1721), the "Life of Colonel Jack" and the "Journal of the Plague in 1665" (1722), the "Adventures of Roxana" (1724), a "New Voyage round the World, by a Course never sailed before" (1725), the "Memoirs of a Cavalier," the "Political History of the Devil," and several others. He also wrote important economic and commercial treatises, entitled an "Essay on the Treaty of Commerce with France," a "Plan of the English Commerce," and "Giving Alms no Charity." Of his later novels Charles Lamb said: "While all ages and descriptions of people hang delighted over Robinson Crusoe, and shall continue to do so, we trust, while the world lasts, how few comparatively will bear to be told that there exist other fictitious narratives by the same writer, four of them at least of no inferior interest: Roxana, Singleton, Moll Flanders, Colonel Jack, are all genuine offspring of the same father. They are, in their way, as full of incident, and some of them every bit as romantic." The most prominent characteristic of his fictions is the distinctness of reality which he gives to them by the elaborate and precise statement of details. It is this quality which made Dr. Johnson esteem the account of Captain George Carleton a record of facts, Lord Chatham quote the "Memoirs of a Cavalier" as a genuine piece of biography, Dr. Mead regard his narrative of the plague in London as the result of personal observation, and which surprised the mass of readers into giving credence to the apparition of Mrs. Veal at Canterbury, "Sept. 8, 1705." His style is distinguished by a simplicity and homeliness which he may have learned from reading Bunyan. After an indefatigable and checkered life, Defoe died in the parish of his birth, insolvent, and the author of 210 books and pamphlets. He thus summed up the scenes of his career in a distich:

> No man has tasted different fortunes more;
> And thirteen times I have been rich and poor.

He adds: "In the school of affliction I have learned more philosophy than at the academy, and more divinity than from the pulpit; . . . . and in less than half a year have tasted the difference between the closet of a king and the dungeon of Newgate. I have suffered deeply for cleaving to principles." Though remembered chiefly as a novelist, he was during 30 years a leader in the fierce partisan strife by which, under William of Orange, constitutional liberty was realized in England, and has been pronounced "the most

thorough Englishman and writer of his day, a model of integrity, and as consistent, sincere, and brave as he was gifted." The best editions of his works, though incomplete, are that of London (3 vols. 1840–'43), with a memoir by William Hazlitt, and that of Oxford (20 vols., 1840–'41), with memoirs and notes by Sir Walter Scott and others.

DEFRÉMERY, Charles, a French orientalist, born at Cambrai, Dec. 8, 1822, devoted himself to the study of the Arabic and Persian languages, and in 1843 became a member of the Asiatic society in Paris. He is the author of several translations from oriental languages, among others of the travels of Ibn Batuta, published with annotations (1848–'51, 2 vols. 8vo; reprinted, with the original Arabic, 1853–'56, 3 vols. 8vo.), and of many other translations from the Persian and Arabic, and is one of the contributors to the *Journal Asiatique* of Paris. The first part of a series of original articles written by him for that periodical was published in 1856, under the title of *Mémoires d'histoire orientale*.

DEFTER-DAR (a Persian word signifying literally book-keeper), the title in Persia and Turkey of the finance minister. In the Ottoman empire, he sits in the divan, disposes of all the public money, and publishes firmans in his own name without referring to the grand vizier. The *defter-dar capoussy*, or department of the ministry of finance, has 33 bureaus, 3 of which are designed only for the registry of pious foundations in favor of hospitals, mosques, and temples, not only at Constantinople, but in the most distant provinces of the empire. Among the other bureaus are distributed the care of the taxes and tributes, the products of the mines and other state property, and the payment of all the officers, civil and military, of the empire.

DEGER, Ernst, a German painter of the Düsseldorf school, born at Böckenem, Hanover, April 15, 1809. He studied at Berlin and afterward at Düsseldorf, under Wilhelm von Schadow. His first efforts were oil pictures, among which there are some altarpieces of merit, especially a madonna and child in the church of St. Andrew, at Düsseldorf. In 1851 he completed the fresco painting for the church of St. Apollinaris, near Remagen, on the Rhine. Since 1851 he has been engaged upon paintings for the chapel of the castle of Stolzenfels. In 1857 he sent for exhibition at the *salon* of Paris a picture of the infant Jesus. He is a professor in the academy of fine arts in Munich.

DE GERANDO. See Gerando.

DEGRAND, Pierre P. F., a public-spirited Frenchman, born in Marseilles in the latter part of the 18th century, died Dec. 23, 1855, in Boston, Mass., where, since the beginning of this century, he had been established as a broker and merchant. For many years he published a commercial paper, the "Weekly Report." He zealously promoted railroads and other public enterprises. He bequeathed about $120,000 to public uses. A large part of this was left to Harvard college, for the purpose of supplying the library with French books on scientific subjects; another part was given to the city of Boston, the income to be expended in purchasing books of amusement for the use of the children of the public schools; the rest was divided among 8 charitable institutions.

DEGREE, in algebra, the number expressing the greatest number of times which an unknown quantity enters any term as a factor. Thus, if x be an unknown quantity, $4x^3+7x^2=8$, is an equation of the third degree. The unknown quantity may, in general, have as many different values as there are units in the degree of the equation.—A degree in trigonometry signifies $\frac{1}{360}$ part of a right angle, and is indicated by a small circle near the top of the figure; thus, 30° signifies the $\frac{1}{12}$ part of a right angle. Each degree may be divided into 60 minutes, each minute into 60 seconds; thus, 31° 12′ 15″ is read 31 degrees, 12 minutes, 15 seconds. In the French decimal system the right angle was divided into 100°, each degree into 100 minutes, &c.; but that method never came into general use. —A Degree of Latitude is the distance N. or S. between 2 places on the same meridian at which plumb lines would make an angle of one degree with each other. Owing to the flattening of the earth toward the poles, this distance increases in length as the observer goes N. or S.; being about 2,740 feet more at latitude 60° than at the equator. Many careful measurements of a degree have been made, by various European governments, not only in their own territories, but in South America, India, and Africa. The most northern accurate measurement was in Lapland; the most southern at the cape of Good Hope; and measurements have also been taken both in India and South America, almost exactly upon the equator. The longest arcs measured are those in France, measured by Mechain and Delambre, and that in India, measured by Col. Lambton and Capt. Everest; the first being over 12°, the second nearly 16°. From a complete discussion of all the observations, Bessel deduces the following results: the diameter of the earth at the equator is 41,847,194 English feet; the diameter through the poles 41,707,308 English feet; so that the difference of the diameters, divided by the longest diameter, gives us almost exactly the quotient of 1 divided by 300 ($\frac{1}{300}$). These results of Bessel are adopted in the United States coast survey, and agree not only with the results of terrestrial measurements, but with the celestial phenomena that depend upon the ellipticity of the earth. It is remarkable that this, the only way of determining the size of the earth, was invented and put in practice by Eratosthenes, in Egypt, in the 3d century B.C. —A Degree of Longitude is the distance between 2 places of the same latitude, the difference of whose clocks is exactly 4 minutes—in other words, the planes of whose meridians make an angle of 1° with each other. The length of a degree of longitude is at the equator 69.16 statute miles; at latitude 20° it is about

65.015 miles; at latitude 30° it is reduced to 59.944; at 40° to 53.053; and at 50° to 44.342.

DEHAVEN, Edwin J., an officer in the U. S. navy, a native of Pennsylvania, entered the navy as midshipman in Oct. 1829, and is now (Jan. 1859) near the head of the list of lieutenants. He served in the exploring expedition under Lieut. Wilkes, 1839 to 1842, and commanded with distinguished ability and zeal the first expedition fitted out at the expense of Henry Grinnell, Esq., of New York, to search for Sir John Franklin. This expedition sailed from New York, May 24, 1850, and was absent a little over 16 months, wintering within the arctic circle. It consisted of 2 small brigs, the Advance of 140, and the Rescue of 90 tons. A particular account of it has been given by Dr. Kane.

DEHON, Theodore, D.D., bishop of the Protestant Episcopal church in South Carolina, born in Boston, Mass., in 1776, died suddenly of malignant fever in Charleston, S. C., Aug. 6, 1817. He was graduated at Harvard college in 1795, entered the ministry of the Episcopal church, became rector of Trinity church, Newport, R. I., in 1798, and rector of St. Michael's church, Charleston, in 1809. In 1812 he accepted the episcopate of South Carolina, and during the succeeding 5 years labored earnestly and zealously in the discharge of his weighty duties. Beside a number of occasional sermons published during his lifetime, 2 volumes of his "Discourses" were issued in 1821. Bishop Dehon ranked high in his day as a preacher, and died very much lamented.

DEISM (Lat. *Deus*, God), the belief in the existence of God. By usage, the term deist is applied only to those who profess natural and deny revealed religion, and is specially applied to the English free-thinkers of the 17th and 18th centuries. The earliest of these was Lord Herbert of Cherbury, whose work *De Veritate* was published at Paris in 1624. Dr. Leland includes in his "View of the Deistical Writers" Herbert, Hobbes, Blount, Toland, Shaftesbury, Anthony Collins, Woolston, Tindal, Morgan, Chubb, Hume, and Bolingbroke.

DEJAZET, Marie Virginie, a French actress, born in Paris about 1797, began her career at the age of 5, in the *théâtre des Capucines*, and continued on the stage in Paris and the provinces, with but little intermission, till 1855, when she played a farewell engagement at the *Gaieté* theatre—the graceful and sprightly qualities which for so many years had made her a public favorite in France, being but little impaired by age. She excelled in the personification of soubrettes and in male attire; and won perhaps her most brilliant laurels in *Les premières armes de Richelieu* and in *Napoléon à Brienne*. What added powerfully to the interest which she created was her manner of singing the songs interspersed in the plays.

DEJEAN, Jean François Aimé, count, a general and peer of France, born Oct. 6, 1749, died May 12, 1824, gained a high reputation by his administrative and military abilities.—His son, Pierre François Auguste, born Aug. 10, 1780, died in 1845, likewise held a high position in the army, and was an eminent entomologist, and one of the most celebrated collectors of *coleoptera* in modern times. He published a catalogue of his collection (3d ed., Paris, 1837–'38), exhibiting the number of species in each genus, and indicating their localities. He is the author of *Spécies générales des coléoptères* (6 vols. in 7, 8vo., Paris, 1825–'39), and wrote in concert with Boisduval and Aubé, *Iconographie et histoire naturelle des coléoptères d'Europe* (5 vols. 8vo., with 264 colored plates, 1829–'40).

DE KALB. I. A N. W. co. of Ga., bounded N. by Chattahoochee river; area, 291 sq. m.; pop. in 1852, 16,552, of whom 3,708 were slaves. It has an elevated and somewhat uneven surface. Stone mountain, in the eastern part, is considered one of the greatest natural curiosities in the state. The soil of the river bottoms is remarkably rich. Iron is found in the county, granite is abundant, and gold has been discovered in small quantities. At Decatur are chalybeate springs. The productions in 1850 (since which time the county has been divided to form Fulton) were 2,397 bales of cotton, 432,435 bushels of corn, 86,047 of oats, and 73,070 of sweet potatoes. There were 34 churches, and 728 pupils attending public schools. Value of real estate in 1856, $1,077,478. The county was named in honor of Baron De Kalb, who fell at the battle of Camden in 1780. The Georgia railroad passes through Decatur, the capital. II. A N. E. co. of Ala., bordering on Ga., drained by Willis creek, an affluent of Coosa river, and Town creek, of the Tennessee; area, about 775 sq. m.; pop. in 1850, 8,245, of whom 506 were slaves. The valley of Willis creek is a fertile and well cultivated tract of country, about 60 m. long by 5 m. broad, enclosed by Lookout mountain on the S. E. and Sand mountain on the N. W. The county is well supplied with water power, and abounds with magnificent scenery. In 1850 the productions were 363,225 bushels of corn, 75,550 of oats, and 34,377 of sweet potatoes. There were 22 churches, and 565 pupils attending public schools. Capital, Lebanon. III. A N. central co. of Tenn.; area, about 300 sq. m.; pop. in 1850, 8,016, comprising 668 slaves. It is watered by a number of mill streams, and has a diversified surface and a good soil. In 1850 it produced 417,251 bushels of corn, and 57,361 lbs. of tobacco. It contained 12 churches, and there were 1,912 pupils in the public schools. Capital, Smithville. IV. A N. E. co. of Ind., bordering on Ohio, drained by the St. Joseph's and some smaller rivers; area, 346 sq. m.; pop. in 1850, 8,251. The surface is undulating. The soil is fertile, and in 1850 produced 139,986 bushels of corn, 75,995 of wheat, 34,366 of oats, and 4,660 tons of hay. There were 2 churches, and 1,600 pupils attending public schools. The county was formed in 1836. Capital, Auburn. V. A N. co. of Ill.; area, 648 sq. m.; pop. in 1855, 13,636. It has a rolling surface, and a fertile soil. Most of the

land is occupied by prairies, but there are tracts of valuable timber. In 1850 the productions were 221,796 bushels of wheat, 215,733 of corn, 138,903 of oats, 21,193 tons of hay, and 138,989 lbs. of butter. There were 2 churches, and 1,865 pupils attending public schools. Capital, Sycamore. VI. A N. W. co. of Mo., drained by several small streams which flow into Grand and Platte rivers; area, 441 sq. m.; pop. in 1856, 2,689, comprising 77 slaves. The surface is occupied partly by prairies and partly by woodlands. The soil is very fertile, and in 1850 produced 103,865 bushels of corn, 11,731 of wheat, 13,547 of oats, 108 tons of hay, and 30,375 lbs. of butter. De Kalb was formed out of a portion of Clinton co. Capital, Maysville.

DE KALB, John, baron, a major-general in the American army during the war of the revolution, born about 1732, in Alsace, a German province in possession of France, and educated in the art of war in the French army. In 1762 he visited the Anglo-American colonies as a secret agent of the French government. He was a brigadier in the French service, when, Nov. 7, 1776, he made with Franklin and Silas Deane an engagement to serve in the forces of the revolted colonies; and in 1777 he accompanied Lafayette to America. Congress appointed him a major-general, Sept. 15, 1777, after which he joined the main army under Washington, and was active in the events near Philadelphia, which preceded the encampment at Valley Forge. He served in New Jersey and Maryland, till, in April, 1780, he was sent to reenforce Gen. Lincoln, then besieged in Charleston, but arrived too late. He was second in command under Gen. Gates; and in the disastrous battle of Camden, Aug. 16, 1780, was at the head of the Maryland and Delaware troops, who maintained their ground till Cornwallis concentrated his whole force upon them. He fell, pierced with 11 wounds, in the charge upon his regiments before they gave way. He died at Camden 3 days afterward, and a monument was erected there to his memory in 1825, Lafayette placing the corner stone.

DE LA BECHE, Sir Henry Thomas, an English geologist, born near London in 1796, died April 13, 1855. He was the only son of Col. Thomas de la Beche of Jamaica, and was educated for the army, which he entered in 1814. Soon afterward he retired, and in 1818 married and settled in Dorsetshire. In 1817 he became a fellow of the geological society, of which he was subsequently elected secretary, and in 1847 president. During these and some succeeding years he pursued investigations into the geology of the counties of Devon, Dorset, and Pembroke; wrote "Observations on the Temperature and Depth of the Lake of Geneva;" and subsequently, in conjunction with the Rev. Mr. Conybeare, published an account of the plesiosaurus, under the title of "Discovery of a new Fossil Animal forming a Link between the Ichthyosaurus and Crocodile." In 1824 he visited his patrimonial estate in Jamaica, attempted to ameliorate the condition of his slaves, and wrote a paper on the geology of the island. Returning to England, he continued his geological researches with great assiduity. In 1831 he published his "Geological Manual," in 1834 "Researches in Theoretical Geology," in 1835 a volume, "How to observe Geology," and in 1851, "Geological Observer." A suggestion which he offered in connection with the government topographical survey then being made, led to his being appointed director-general of the geological survey of the United Kingdom; and when, mainly by his exertions, a geological museum with free lectures was added thereto, he was further nominated director of the museum of practical geology (now merged in the school of mines and of science), which appointments he held till his death, when he was succeeded in the latter office by the present incumbent, Sir Roderic Murchison. Beside these, he was member of many scientific commissions appointed by the government, as on the health of towns, explosions in collieries, selection of coal for the steam navy, building-stone for the houses of parliament, mining department of the world's fair, &c. Toward the close of his life he was knighted, made a chevalier of the Belgian order of Leopold, and of the Danish order of Danneborg, and a corresponding member of the French academy of sciences. For several years his limbs were paralyzed, but his intellect remained unimpaired, and he retained the tact, capacity for work, and cheerful temperament of his earlier days. He was buried in Kensal Green cemetery, London.

DELACROIX, Ferdinand Victor Eugène, a French painter, born near Paris, April 26, 1799. He first became known by some able criticisms on art; studied painting under Pierre Guérin; but from the very commencement of his career he abandoned the classic school, and may be considered the founder of the romantic. His first picture, "Dante and Virgil," was exhibited in 1822. His second work, the "Massacre of Scio," is considered one of the most striking pictures of the French school of the 19th century. He has since executed an immense number of works on a wide range of subjects. In 1832 he was sent by the government on a mission to Morocco, and while there he sketched a great variety of views and costumes, which were afterward reproduced in some very interesting and original pictures. The decoration of one of the halls of the palais Bourbon, consisting of 4 allegorical paintings, was his work. His productions are distinguished by their life and energy, but his coloring is more powerful than harmonious. His most esteemed works figured at the great exhibition of 1855, as well as a new picture representing a "Lion Hunt."

DELAGOA BAY, the largest bay on the S. E. coast of Africa, in lat. 26° S., and long. 33° E. It is formed by the Indian ocean, and stretches N. and S. about 50 m., with a breadth of from 16 to 20 m. It is accessible and affords a good anchorage to vessels of the largest class,

and will doubtless continue an important place, as there is no other port within a great distance admitting vessels drawing over 8 feet of water. The land near the shore is low and marshy, but rises after a short distance inland.

DELALANDE, Pierre Antoine, a French naturalist and traveller, born at Versailles, March 27, 1787, died July 27, 1823. He was early employed with his father in the museum of natural history in Paris, devoted himself for a time to painting, and became assistant of Geoffroy St. Hilaire, whom he accompanied on his scientific expedition to Portugal in 1808. In 1813 he was sent to the south of France as agent of the museum. In 1816 he went to Brazil to collect objects of natural history. His most important scientific voyage was to Cape Colony, the country of the Hottentots, and Caffraria, in the south of Africa, in 1818 and 1819, in which he made a zoological collection of 13,500 specimens, belonging to more than 1,600 different species; an herbarium of more than 6,000 specimens, comprising 920 species; and collected 300 valuable mineralogical specimens, and 10,000 specimens of insects. Among the animals were a hippopotamus, double-horned rhinoceros, giraffe, whale, and aard wolf. He also brought back many human crania. His death occurred before he was able to write the narrative of his observations. He read a summary of them before the academy of sciences, which was printed in vol. viii. of the *Mémoires du muséum d'histoire naturelle.*

DELAMBRE, Jean Baptiste Joseph, a French astronomer, born in Amiens, Sept. 19, 1749, died in Paris, Aug. 19, 1822. Till the age of 20 years his eyes were so weak that, in anticipation of blindness, he devoted himself with the greatest zeal to his studies. Becoming a private tutor after leaving college, he occupied his leisure in reading Italian, English, and Greek literature, studying mathematics at first only sufficiently to teach his pupils. From 1780 he devoted himself to astronomy, being first the pupil and then the collaborator of Lalande, who said that "Delambre was his best work." In 1790 he gained the prize of the academy of sciences for his tables of Uranus, though that planet had completed but a small arc of its orbit after its discovery by Herschel; and in 1792 another prize was given to him for his tables of the satellites of Jupiter. For these labors he was unanimously elected a member of the academy in 1792. He was associated with Mechain in measuring an arc of the meridian from Dunkirk to Barcelona, an important labor, which, being interrupted by the revolution, was not finished till 1799, and a complete account of which was given by Delambre in his *Base du système métrique décimal* (3 vols., Paris, 1806–'10). He entered the bureau of longitudes in 1795, the institute of France at its formation in the same year, became inspector-general of studies in 1802, perpetual secretary of the institute for mathematical sciences in 1803, successor of Lalande in the college of France in 1807, and treasurer of the imperial university in 1808. This office was suppressed at the restoration, and from that time he pursued his researches in retirement. After having spent 30 years of his career in the most severe astronomical and mathematical calculations, he undertook to write the history of astronomy from the remotest period, 5 volumes of which were published before his death (Paris, 1817–'21), and a posthumous volume on the history of astronomy in the 18th century was issued in 1827. This work abounds in original materials culled from the scientific treatises of different ages and many languages. Among his other writings, all of which are marked by an elegant simplicity of style, are a report on the progress of the mathematical sciences since 1789 (Paris, 1810); *Astronomie théorique et pratique* (3 vols., Paris, 1814); and numerous papers in the transactions of different European academies of science.

DE LANCEY, William Heathcote, D.D., D.C.L., an American Episcopal divine, bishop of the diocese of western New York, born in Westchester co., N. Y., Oct. 8, 1797. He was graduated at Yale college in 1817, studied theology under the direction of Bishop Hobart, and received deacon's orders in 1819. Ordained to the priesthood in Trinity church, New York, in 1822, he soon after became personal assistant of the venerable Bishop White of Philadelphia, in the 3 churches of which that prelate was rector, and in the succeeding year he was unanimously elected one of the regular assistant ministers of those churches. He was annually chosen secretary of the diocesan convention of Pennsylvania from 1823 till 1830, and was secretary of the house of bishops in the general convention of the Episcopal church of the United States from 1823 till 1829. Upon the reorganization of the university of Pennsylvania in 1828, he was chosen provost of that institution, and thereupon resigned his pastoral charge. He remained provost 5 years, and then resumed the office of assistant minister of St. Peter's church, one of the 3 of which Bishop White was rector. He travelled in Europe in 1835, and on his return, after the death of Bishop White, succeeded to the rectorship of St. Peter's church. In 1838 the diocese of New York, comprising the whole state, was divided, the eastern portion retaining the old name; and at the primary convention of the new diocese, held at Geneva, Nov. 1, 1838, Dr. De Lancey was chosen its first bishop, and he was consecrated May 9, 1839. He removed to Geneva, the seat of the diocesan college, now called the Hobart free college, which was chiefly indebted to his efficient efforts for its support. He also instituted a system of diocesan missions, by which a corps of laborers unusually large in proportion to the population and wealth of the diocese have been sustained to the present time, without incurring debt. In 1840, by his recommendation, a fund for the relief of infirm and aged clergy of the diocese was established, which, beside accomplishing its object, has accumulated a capital of about $5,000.

His sermon on the office of bishop, preached Dec. 29, 1842, at the consecration of Dr. Eastburn as bishop of Massachusetts, was widely circulated and highly esteemed. In 1846, at a meeting of the trustees of the general theological seminary of New York city, he made a proposition for the dissolution of that school as a general institution of the church, with the view of counteracting the distrust and hostility of which it was the object, and also of preparing the way for the realization of his own scheme of diocesan schools. Though this measure was not adopted, in 1855 he brought forward his plan for a diocesan "training school," to be supported by a charity foundation, and to afford the requisite education to all persons qualified and disposed to enter upon the work of the ministry. In 1852 he visited England as a delegate from the Episcopal bishops of the United States. In 1858 Bishop De Lancey had ordained 113 deacons and 125 priests, had consecrated 80 church edifices, and admitted to the communion of the church by the rite of confirmation 14,697 persons.

DELANE. I. William Augustus Frederic, an English journalist, born in 1793, died in Norwich, July 29, 1857. He was memorable for his long and successful connection with the "London Times," which earned its sobriquet of the "Thunderer" during his administration of its affairs, from the strong and telling character of the articles contributed by his friend and associate, Capt. Edward Sterling. Mr. Delane was a man of great executive capacity, extreme good sense, and practical sagacity. He wrote indeed but little, and earned the reputation for ability which he enjoyed among his associates, rather by the steady and uniform exhibition of an imperturbable discretion in judging what should be said, and who should say it, than by his own lucubrations. He was also for some time charged with grave financial responsibilities in connection with the "Times," and came in this way to be so vexatiously implicated in certain transactions of Mr. T. M. Alsager that he conceived it to be due to himself to break off his connection with the Messrs. Walter, the proprietors of the "Times." This he did, however, without impairing the friendly relations that subsisted between them in private life, and without any imputation upon his own character. He was afterward for a short time intrusted with the charge of the "Daily News," but eventually accepted the office of treasurer of the Kent county courts, and retired from journalism altogether. He died at Hillesden, the residence of his eldest son, in Norfolk; and it curiously illustrates the studiously impersonal character sought to be stamped upon the "Times," that no notice whatever was taken by that journal of the decease of a man to whom it was so much indebted for the successful establishment of its system of management. II. John Thaddeus, the 2d son of the preceding, born in 1819, took his degree as bachelor at Magdalen hall, Oxford, in 1840, and as master of arts in 1846. He completed his terms as a barrister, but has never engaged in the actual practice of his profession. He was at first employed as a leading writer upon the "Times," but on the reconstruction of the staff of that journal, after his father's retirement, he assumed the political control of it, the financial and general business management passing into the hands of Mr. Mowbray Morris. Mr. Delane is the first English journalist who has achieved a prominent contemporary recognition, by the public at large, of his connection with the "Times." The exposures made by the "Times" and its correspondents, during the Crimean war in 1854, of military mismanagement on the part of the English government, brought Mr. Delane conspicuously forward as an individual, and invested him suddenly with something of the formidable power that had previously been conceded to that mysterious being, "the editor of the Times." In 1856, at the time of the presidential election, Mr. Delane visited the United States, making a tour of 4 months, in the course of which he made himself acquainted with the leading men of all parties, and familiarized himself with the best aspects of American life. The results of this brief but varied experience have since been discernible in the much greater intelligence, justice, and good will with which American affairs have been treated by the journal over which he presides.

DELAROCHE, Hippolyte, better known as Paul, which name he assumed at the age of 15 or thereabout, an eminent French historical painter, born in Paris, July 17, 1797, died there, Nov. 4, 1856. Early evincing a taste for painting, he studied landscape in order not to interfere with the prospects of an elder brother who had devoted himself to the department of history. After several fruitless attempts to secure the academy prize for landscape painting, he renounced that branch of the art, and in 1816, in obedience to his inclinations, entered the studio of Baron Gros, where his talents were rapidly developed. Gros had succeeded to a great extent in freeing himself from the influence of David's dry, classic style, and his pupil avoided it still more, without however adopting all the ideas of the romantic school. He chose rather to take a middle course between the two, and to create a sort of eclectic style, which should represent all the improvements in art and its general progress during the 19th century. Hence he and his school have been called the "Eclectics," in contradistinction to the romantic school of Delacroix and the classic school of David. In 1819 his first picture, "Naphtali in the Desert," was exhibited, and from that time until the great industrial exhibition in Paris in 1855, when a collection was made of his chief productions, almost every year witnessed the execution by his pencil of one or more striking works. His subjects were generally taken from English or French modern history, and he was fond of drawing upon the misfortunes of fallen greatness as a source of inspiration. His "Children of Edward IV. in the Tower," "Joan

of Arc in Prison," the "Execution of Lady Jane Grey," "Charles I. in the Guardroom insulted by the Parliamentary Soldiers," "Strafford on his way to the Scaffold," the "Young Pretender succored by Flora Macdonald," and "Marie Antoinette before the Revolutionary Tribunal," are good specimens of the subdued yet impressive manner in which he was accustomed to handle this class of subjects. Still more powerful was his "Cromwell contemplating the Corpse of Charles I.," generally considered the best of his series illustrating the civil wars in England, and indeed of all his pictures on English subjects. This purely imaginative scene is treated with a simplicity and dignity in keeping with the theme, and aptly illustrates Delaroche's capacity to delineate a striking historical episode without resorting to exaggeration of form or expression. His "Death of Queen Elizabeth," an earlier work, is less severe in style, and less historically accurate. Among his pictures from French history may be mentioned a "Scene in the Massacre of St. Bartholomew;" "Cardinal Richelieu in a Barge on the Rhone conducting De Thou and Cinq-Mars to Execution;" the "Death of Cardinal Mazarin;" the "Assassination of the Duke of Guise," a work of great power, for which the duke of Orleans is said to have paid 52,000 francs; a series of 4, representing the "Baptism of Clovis," the "Oath of Pepin the Short," the "Passage of the Alps by Charlemagne," and the "Coronation of Charlemagne at Rome," painted for the gallery of Versailles; the "Destruction of the Bastile," and the "Girondists in Prison," one of his last works. In addition to these, his "Napoleon at Fontainebleau," and "Napoleon at St. Bernard," of both of which he made several copies, have obtained great popularity. The work, however, which occupied the greatest share of his attention, and upon which he intended that his reputation should rest, is his fresco painting of the hemicycle of the *Palais des beaux arts*, a composition of great size and merit, representing the illustrious masters of art of all ages. Apelles, Phidias, and Ictinus preside over this assemblage; at their feet stand 4 female figures, typifying Greek, Roman, Middle Age, and Renaissance art, while below, on each side in animated groups, are seen the great painters, sculptors, and architects of the world. This picture includes upward of 80 figures of the size of life, and is admirable for its elevated tone, simplicity of arrangement, and fulness and force of expression. It cost Delaroche 4 years of incessant labor, and has been beautifully engraved by Henriquel Dupont. In the winter of 1855 the picture was much injured by fire, and the anxiety and labor attendant upon the work of restoration, which Delaroche lived to complete with his own hand, are supposed to have hastened his death. At various times of his life, but particularly in the latter part of it, he painted sacred compositions, which are inferior generally in elevation and character to his historical subjects. "Herodias with the Head of John the Baptist" is among the best. Some of his purely domestic subjects, such as a "Mother fondling her Children," are full of grace and sweetness. He painted likenesses of Guizot, Thiers, Lamartine, his father-in-law Horace Vernet, and other distinguished Frenchmen, which show considerable talent for portraiture. Delaroche has not escaped censure for an alleged want of force and imagination in his works, as well as for the simplicity and meagreness of his details. The accessories are sometimes also so highly finished as to detract from the general effect of his pictures. But for elevated manner, correctness of design, and beauty of drawing and color, he was unsurpassed by any of his contemporaries. His powers seemed to ripen and mellow with age, and his latest works, like the first, continued to reflect his somewhat melancholy and saturnine temperament. His scholarly attainments and mastery of a wide field of art gave great weight to his opinions, and he was regarded as a sort of oracle among his associates. In personal appearance he bore a considerable resemblance to the emperor Napoleon I. The greater part of his works are familiarly known through the medium of excellent engravings, and in 1858 a magnificent collection of photographs of his finished pictures and of many of his sketches and cartoons was published in Paris.

DELAVIGNE, Germain, a French dramatic author, born at Giverny, Feb. 1, 1790. He was educated at the Napoleon lyceum, and received under Louis Philippe an office from the crown. In his literary labors, as in his college studies, he has been associated with Eugène Scribe, in collaboration with whom he has written a large number of highly esteemed vaudevilles, operas, comic operas, and some short romances, as *Les mystères d'Udolphe* (1852), *La nonne sanglante* (1854). With his brother Casimir he wrote the opera of *Charles VI.* (1843).

DELAVIGNE, Jean François Casimir, younger brother of the preceding, a French lyric and dramatic poet, born at Havre, April 4, 1793, died at Lyons, Dec. 11, 1843. He was the son of a merchant, and at first a laborious rather than brilliant student at the Napoleon lyceum in Paris. Only in the latter years of his course he manifested his poetical tastes and talent, while his brother Germain and his life-long friend Eugène Scribe, then his fellow students, were his most intimate associates. His own early ambition was to compose an epic poem, while that of Germain was for success in dramatic composition, and that of Scribe to become a leader at the bar. In 1811 he composed a dithyramb on the birth of the king of Rome, which was printed, attracted general attention, and obtained for him the encouragement of Andrieux, whose uniform custom was to dissuade young men from a literary career, and the more useful protection of Français of Nantes, a high officer of state, who delighted in playing the part of Mæcenas. From the latter he received a slight office, the condition being that he should appear at his desk only once a month, on the

day of payment. Several of his short pieces had been honorably mentioned by the academy, when he adopted a national subject, and published in 1818 his 3 admirable elegies, the *Messéniennes*, so called in allusion to the songs by which the conquered Messenians lamented their country's disasters. Two of these had before been widely circulated in manuscript. France, completely exhausted, twice conquered, and suffering the indignities of invasion, first learned from him the accents of grief for the issue at Waterloo, of indignation for the devastation of the museum, itself the fruit of conquest, and was urged by him anew to union and patriotism when the foreign occupation had ended. Within a year, 22,000 copies of the *Messéniennes* were sold; they accorded so nearly with the national spirit without exciting partisan passion, that Louis XVIII. ordered a sinecure librarianship to be bestowed upon the author; and Delavigne was from this time the favorite poet of the liberal opposition. He wrote 2 elegies on the life and death of Joan of Arc, and then produced his first tragedy, the *Vêpres Siciliennes*, which was performed at the Odeon in 1819, and was received with enthusiasm. It was soon followed by the *Comédiens*, written to ridicule the company of the *théâtre Français* by which his first drama had been rejected, and in 1821 by the *Paria*, in which he pleads the principle of the natural equality of men. His liberal ideas, repeated in several new lyrics, to which also he gave the name of *Messéniennes*, and his association with some of the leaders of the opposition, caused him to lose his humble place under the government, when the duke of Orleans made him librarian of the *palais royal*. The schism between the favorite author and the first dramatic company of the time having been ended, he produced in 1823 his *École des vieillards*, in which Talma and Mlle. Mars played the principal parts, which is esteemed his masterpiece in his first dramatic manner, and which gained him in 1825 admission into the French academy. He had long aspired to this honor, but when he had presented himself at the first election a bishop had been preferred to him, at the second an archbishop, and he had declined persisting when there was a third vacancy, saying that doubtless the pope would be his rival. Refusing a pension now offered him by the government, which he believed hostile to public liberty, he resided during a year in Italy, and returned to find that a great change had taken place in the public taste. The classical drama seemed to have died with Talma, and the romantic school had brought into vogue, and was winning the popular favor for, another class of ideas and dramatic combinations, and even a new style and new forms of versification. His comedy, the *Princesse Aurélie* (1828), was the least favorably received of all his works. While a war of epigrams raged between the defenders of the three unities and the champions of an audacious eccentricity, Delavigne conceived the idea of conciliating the two schools, of uniting classical elegance and purity with romantic boldness—a project which was the ambition, not to say the illusion, of the remainder of his life. He joined himself with the romanticists, with the purpose of proving to them that pity, terror, and overpowering interest were not incompatible with sobriety of action and correctness of language. His *Marino Faliero* (1829), in which he first departed from the ancient rules, mingling tragedy with comedy, and dignity of expression with light vivacity, obtained great success. He had in Italy begun the tragedy of *Louis XI.*, but had abandoned it on the death of Talma, despairing to find any other qualified to perform the principal part, till he witnessed the powers of Ligier, in the part of Faliero. He now set himself to finish it, and was only briefly interrupted by the revolution of 1830, improvising the *Parisienne*, the most popular song at the time of insurrection, and writing also a new *Messénienne* entitled *Une semaine à Paris*. Declining any personal favor from the triumph of the liberal cause, he resumed his labors, and completed *Louis XI.*, which was produced in 1832; it is the greatest work of Delavigne in his second style, and has remained one of the most remarkable dramas on the stage. It was followed by *Les enfants d'Édouard* (1833), *Don Juan d'Autriche*, in prose, and one of his best pieces (1835), *Une famille au temps de Luther* (1836), *La popularité* (1838), *La fille du Cid*, in which he returned to his early manner (1839), and *Le conseiller rapporteur* (1841). It was his custom to compose his dramas entire before writing a word of them, and he had already completed in his mind another tragedy, *Mélusine*, which was his favorite piece, the hero of which was a sort of oriental Faust, when his health rapidly failing prevented him from writing more than the first act and a part of the second. At the approach of winter he started for Italy, but, unable to support the fatigue of the journey, died at Lyons, while his wife was reading to him Sir Walter Scott's "Guy Mannering." His funeral at Paris was attended not only by the most eminent men in literature, art, and politics, but by the populace in throngs. The personal character of Delavigne was most estimable. His works are distinguished as much for their purity of sentiment as their perfection of art; and notwithstanding the concessions which he made to the reigning school, he may justly be called a great classical dramatist. Among his occasional pieces are lyrics in behalf of Greece and Poland. The standard edition of his works is that of 1846, in 6 vols., which has been several times reproduced, and contains a memoir by his brother Germain.

DELAWARE, one of the original states of the American union, situated between lat. 38° 28′ and 39° 50′ N. and long. 75° and 75° 46′ W., having a length N. and S. of 96 m., and a breadth varying from 9 to 12 m. in the N. to 36 or 37 m. on the S. line; area 2,120 sq. m., or 1,356,800 acres; bounded N. by Pennsylvania, W. and S. by Maryland, and E. by Delaware river and bay

(separating Delaware and New Jersey) and the Atlantic ocean. The state is divided into 3 counties, viz.: New Castle in the N., Kent in the middle, and Sussex in the S.; and these are subdivided into hundreds. Wilmington, the most populous and important city, is situated between Brandywine and Christiana creeks, about 1 m. above their confluence. The principal part of the city is built on the S. W. side of a hill, 109 feet above tide. On the N. E. side of the same hill on the Brandywine are a number of flouring mills which have long been celebrated. Wilmington is also largely engaged in the manufacture of steam engines (land and marine), railroad cars, machinery generally, &c., and also powder. The Christiana creek admits vessels drawing 14 feet of water to the town, and those drawing 7 or 8 feet can ascend 8 m. further. The Brandywine has 7 feet of water to the mills. Pop. in 1850, 13,979, and in 1853, 16,163. Dover, the state capital, is situated on Jones's creek, 5 m. from the Delaware. New Castle, on the Delaware, 5 m. S. of Wilmington, is a manufacturing town, and carries on a considerable trade. The other principal places are Georgetown and Lewes in Sussex co.; Milford and Smyrna in Kent co.; and Port Penn and Delaware City, New Castle co. Newark is the seat of Delaware college. The population of Delaware in 1790, and at subsequent decennial periods down to the year 1850, has been as follows:

Census.	White.	Free colored.	Slave.	Total.
1790	46,310	3,899	8,887	59,094
1800	49,852	8,268	6,153	64,273
1810	55,361	13,136	4,177	72,674
1820	55,282	12,958	4,509	72,749
1830	57,601	15,855	3,292	76,748
1840	58,561	16,919	2,605	78,085
1850	71,169	18,073	2,290	91,532

Of the white population in 1850, there were 29,259 males and 29,302 females; of the free colored (blacks 16,425, and mulattoes 1,648), 9,035 males and 9,038 females; and of the slave (blacks 2,207, and mulattoes 83), 1,174 males and 1,116 females. Density, 43.18 to a square mile; proportion to the population of the whole Union, 0.39 per cent. Families (white and free colored), 15,439; dwellings, 15,290. Deaf and dumb, 54: white 48, free colored 4, slave 2; blind, 39: white 25, free colored 14, slave 0; insane, 68: white 48, free colored 20, slave 0; idiotic, 92: white 74, free colored 14, slave 4. Births (white and free colored), 2,495; marriages, 564; deaths, 1,188. Total deaths (including slaves), 1,209. Ages (all classes): under 1 year, 2,554; 1 and under 5, 10,899; 5 and under 10, 13,071; 10 and under 15, 11,700; 15 and under 20, 10,142; 20 and under 30, 15,994; 30 and under 40, 11,208; 40 and under 50, 7,488; 50 and under 60, 4,491; 60 and under 70, 2,484; 70 and under 80, 1,101; 80 and under 90, 279; 90 and under 100, 54; 100 and upward, 9; unknown, 58. Of persons 100 and upward: white 2, free colored 5, and slave 2. White and free colored (total, 89,242), born in Delaware, 72,351; born in other states of the Union, 11,617; born in foreign countries, 5,211; and born in parts unknown, 63. Natives of Delaware resident in other states, 31,965. Occupations of 22,061 (white and free colored) males over 15 years of age: 5,633, commerce, trade, manufactures, mechanic arts, and mining; 7,884, agriculture; 6,663, labor not agricultural; 743, sea and river navigation; 251, law, medicine, and divinity; 581, other pursuits requiring education; 124, government civil service; 69, domestic service; 113 unspecified. Slaveholders, 809, viz.: holders of 1 slave, 320; of 1 and under 5, 352; of 5 and under 10, 117; and of 10 and under 20, 20. Paupers (in 1849–'50), 667, viz.: 569 native and 128 foreign, costing in the year $17,730. Criminals convicted (1849–'50), 22, all native, and (June 1, 1850) in prison 14, all native. Federal population (all free and $\frac{3}{5}$ slaves), 90,616, which entitled the state to one representative in the national congress.—Delaware comprehends the N. E. portion of the low peninsula between Chesapeake bay, Delaware rivers, and the Atlantic ocean. It contains no mountains, but in the N. the surface is beautifully diversified by hill and dale. Southward of Christiana creek the surface is almost a perfect level, and is only relieved by a low table-land or sand ridge, nowhere more than 60 or 70 feet in height, which traverses the state N. and S. near the W. boundary, and forms the watershed of the peninsula. This table-land abounds in swamps, in which most of the rivers and streams have their sources, some flowing W. into Chesapeake bay, and others E. into the Delaware. The Choptank, Nanticoke, and Pokomoke, the head waters of which are in this state, have their greatest lengths in Maryland and flow into the Chesapeake. The Appoquinnimink, Duck, Jones's, Murderkill, Mispilion, Broadkill, Indian, and other rivers and creeks are affluents of the Delaware and Atlantic. The most important streams of Delaware, however, are the Brandywine and Christiana creeks, the former coming in from Pennsylvania, and the latter from the S. W. These unite below Wilmington, and pour their united waters into the Delaware 1 m. below their junction. Many of the smaller rivers are navigable for coasting vessels, but the Christiana is the only one in the state that admits of the entrance of merchant ships. Delaware bay is a fine estuary, about 60 m. in length by 25 or 30 in greatest breadth, but contracting toward the N. to less than 5 m.; and where it opens to the sea between Cape May (lat. 38° 56′ and long. 74° 38′) and Cape Henlopen (lat. 38° 48′ and long. 75° 6′), the width is not more than 15 m. The main channel admits the largest vessels to the head of the bay and into the river, having from 35 to 75 feet of water; but the course is made tortuous and intricate by the numerous shoals which nearly fill the central portion. The western shore of the bay is marshy and low, and that on the Atlantic is beset with sand beaches which enclose shallow

bays, or more properly lagoons. Rehoboth bay, at the mouth of Indian river, is a basin of this description, but admits vessels drawing 6 feet of water. At the S. extremity of the state is the Cypress swamp, a morass 12 m. long and 6 m. wide. This swamp contains a great variety of trees and evergreen shrubs, and is infested with noxious reptiles. For 8 or 10 m. inland from the Delaware the soils are generally rich clays, but thence to the swamps and southward sand prevails. Bog iron ore is found in the swamps, and shell marl occurs abundantly. In the N. there are deposits of kaolin, or porcelain clay, which have supplied the Philadelphia works with that valuable earth. The climate is in general mild and highly favorable to agricultural pursuits. The N. and more elevated region has a remarkably salubrious atmosphere; but where the surface is swampy, as in the S. parts of the state, endemic sickness prevails to a considerable extent. The natural productions are similar to the middle region of the United States generally.—In 1850 Delaware contained 6,063 farms and plantations, enclosing 956,144 acres of land, of which 580,862 acres were improved. Cash value of farms $18,880,031, and of farming implements and machinery $510,279. Average of farms 158 acres, and of value $3,198. Live stock upon farms, &c. (1850): horses 13,852, asses and mules 791, milch cows 19,248, working oxen 9,797, other cattle 24,166, sheep 27,503, swine 36,261, in all valued at $1,849,281; and value of animals slaughtered (1849–'50), $373,665. Agricultural products (1849): wheat 482,511, rye 8,066, oats 604,518, Indian corn 3,145,542, barley 56, and buckwheat 8,615 bushels; potatoes, Irish, 240,542, and sweet, 65,443 bushels; hay, 30,159 tons; hops, 348 lbs.; clover seed, 2,525, and other grass seed, 1,403 bushels; butter, 1,055,308, and cheese, 3,187 lbs.; peas and beans, 4,120 bushels; market garden products, $12,714, and orchard products, $46,574; beeswax and honey, 41,248 lbs.; home-made manufactures, $38,121; flaxseed, 904 bushels; flax, 11,174 lbs.; molasses, 50 gallons; wool, 57,768 lbs.; wine, 145 gallons. The average grain crops of Delaware (bushels per acre) were as follows: wheat 11, Indian corn 20, oats 20, and buckwheat 10. The total value of agricultural products returned by the census of 1840 was $2,877,350, and by that of 1850, $3,117,565. Manufactures, mining, and the mechanic arts: establishments, 531; capital, $2,978,945; raw material used, $2,864,607; hands employed, 3,888, viz.: 3,237 males and 651 females; annual wages, $936,924; products, $4,649,296; profit, 28.46 per cent. Cotton factories 12, capital $460,100, cotton used 4,730 bales, total value of raw material $312,068, products $538,439; woollen factories 8, capital $148,500, wool used 393,000 lbs., value of raw material $204,172, products $251,000; cast-iron works 13, capital $373,000, pig iron consumed 4,400 tons, value of raw material $153,852, products $267,462; wrought-iron works 3, capital $75,000, value of raw material $35,410, and products $38,200. The manufactures of Delaware (including family products) were valued in 1820 at $1,318,891, in 1830 at $1,991,000, in 1840 at $2,709,068, and in 1850 at $4,687,427.—The exports of Delaware for the year ending June 30, 1858, were valued at $106,571, and the imports at $2,821; and the shipping cleared amounted to 2,871 tons, and entered to 845 tons, all American. The coasting trade is more extensive, and is carried on chiefly for the supply of the Philadelphia markets. Shipping owned in the state 21,258 tons, viz.: 3,643 registered and 11,992 enrolled and licensed; and of this 15,635 (including 1,057 steam) belonged to the Wilmington, and 5,623 (including 203 steam) to the New Castle district. In 1859 (Jan.), Delaware had 12 banks, capital $1,638,185, loans and discounts $3,000,285, stocks $22,610, real estate $81,499, due by other banks $308,222, notes of other banks $61,446, specie funds $114,812, specie $217,312, circulation $960,846, deposits $832,657, due to other banks $86,180. On June 30, 1858, Delaware contained 115 m. of completed railroad, viz.: the Delaware railroad, 71 m. long, extending from Seaford to a junction with the New Castle and Frenchtown railroad, 7 m. W. from New Castle, cost $1,146,310; the New Castle and Frenchtown railroad, 16 m. long, from New Castle on the Delaware to Frenchtown on Elk creek, an arm of Chesapeake bay, cost $380,000; the New Castle and Wilmington railroad, 4.7 m., cost $100,000; and a section of the Philadelphia, Wilmington, and Baltimore railroad, about 23 m. This system connects Wilmington with Philadelphia and Baltimore, and with the state throughout its whole length, and also the waters of the Delaware and Chesapeake. There are also in course of construction 2 other railroads, viz.: the Junction and Breakwater, intended to connect Milford and Lewes with the Delaware railroad; and the Delaware and Maryland, an extension of the same line from Seaford to the head of steam navigation on the Nanticoke. Ultimately, however, it is proposed to carry the main line of road through Maryland and Virginia to Cape Charles. From the Nanticoke and the cape, Norfolk will be reached by steamers. The Chesapeake and Delaware canal connects by a channel navigable for coasting vessels the waters so called. It extends from Delaware City, 46 m. below Philadelphia, to Back creek, a navigable branch of Elk river in Maryland, 13½ m., and is 66 ft. wide at the top and 10 ft. deep, with 2 tide and 2 lift locks, and a deep cut for 4 m. through a hill 90 ft. high. This important work was completed in 1829 at a cost of $2,250,000. The total length of post routes in the state on June 30, 1858, was 562 m., of which 85 m. was railroad, 303 m. coach, and 174 m. not specified. —The census of 1850 presents the following statistics regarding churches, schools, the press, &c. Churches 180, viz.: Baptist 12, Episcopal 21, Friends 9, Methodist 106, Presbyterian 26, Roman Catholic 3, Union 1, and minor sects 2, which together furnished accommodation for

55,741 persons, and were valued at $340,345. Colleges 2, professors 16, students 144, annual income $17,200; academies and private schools 65, teachers 94, pupils 2,011, annual income $47,832; primary and public schools 194, teachers 214, pupils 8,970, annual income $43,-861. The number of children attending school during the year as returned by families was 14,403, viz.: 14,077 natives, and 326 foreigners. Newspapers and periodicals 10 (circulating 75,000, or annually 421,200 copies), viz.: 3 semi-weekly and 7 weekly, of which 2 were literary and miscellaneous, and 8 political. Libraries (other than private) 17, with 17,950 volumes, viz.: public 4, with 10,250 vols.; Sunday-school 12, with 2,700 vols.; and college 1, with 5,000 vols. The number of free schools in operation in 1856 was 233; scholars, 11,468; average length of schools, 7.6 months; receipts, $80,509, of which from school fund, $27,452, and district contributions, $53,057; expenditures, $78,253. The capital of the permanent school fund amounts to $440,505. The collegiate institutions are: Delaware college at Newark, founded in 1833, and which in 1858 had 6 professors, 50 students, and a library of 10,000 vols.; and St. Mary's college at Wilmington, a Roman Catholic school, founded in 1847, and which in 1858 had 7 professors, 110 students, and a library of 2,500 vols.—The constitution of Delaware grants the right of voting to all free white male citizens 21 years of age, who have resided in the state one year, and in the county one month next preceding an election. The general assembly consists of a senate of 9 members (3 from each county), chosen for 4 years, and a house of representatives of 21 members, chosen for 2 years. Senators must be 27 years of age, and be possessed of 200 acres of freehold land, and representatives must be 24 years of age. Pay, $3 per diem and mileage. The sessions are biennial. The governor is elected for 4 years, and has a salary of $1,333; he must be 30 years of age, and have resided in the state 6 years next before election. The state treasurer and auditor (salary $500 each) are elected by the general assembly for 2 years; the term of the secretary of state (salary $400 and fees) is 4 years. There are 5 judges, one of whom is chancellor and president of the orphans' court, and of the other 4 one is chief justice of the state, and 3 are associate justices, one resident in each county. The chief justice and 2 of the associates form the superior court and court of general sessions, and all the judges, except the chancellor, form the court of oyer and terminer. The court of errors and appeals is composed of 3 or more judges. The orphans' court consists of the chancellor and the associate judge of the county. Judges are appointed by the governor, and hold office during good behavior. Probate courts are held by registers of wills, with appeal to the superior court. The public income is derived from corporation taxes, dividends, interest on loans, &c., and in 1857 amounted to $46,000. The disbursements for the year were about $39,000. The state has no debt, but has permanent resources amounting to $549,755, viz.: invested capital $109,250, and school fund $440,505. The valuation of taxable property in 1856 was $30,466,924. There is, however, no taxation for state purposes.—Delaware takes its name from Lord De La Ware, governor of Virginia, who entered the bay in 1610; but the discovery of the Delaware was made by Hudson in 1609. In 1629, one Godyn, a director in the Dutch West India company, in whose service Hudson had sailed, purchased of the natives a tract of land near the mouth of the river; and next year De Vries with 30 colonists, arriving out from Holland, settled near Lewes. Three years later the whole colony was destroyed by the natives. In 1637 the Swedish West India company sent out a colony of Swedes and Finns, which arrived at Cape Henlopen early in 1638, and after purchasing all the lands from the cape to the falls near Trenton, erected a fort at the mouth of Christiana creek. They named the country Nya Sveriga, or New Sweden. The subsequent settlements of the Swedes were mostly within the present limits of Pennsylvania, and in 1643 their headquarters were erected on the island of Tinicum, a few miles below Philadelphia. These proceedings were protested against by the Dutch of New Amsterdam, who claimed the country by right of discovery and settlement, and with a view to the expulsion of the intruders built Fort Casimir (now New Castle), 5 m. S. of Fort Christiana. This, however, was captured by the Swedes in 1654; but the next year the Dutch from New Netherlands attacked and reduced the Swedish forts, and sent to Europe all the colonists who refused allegiance to Holland. Thus ended the transient connection of Sweden with the colonial history of the United States. From this period to 1664, when New Netherlands was conquered by the English, the Delaware settlements continued under the control of the Dutch authorities. The duke of York now came into possession of all the Dutch had occupied, and the English laws were established on both sides of the river. In the mean time, however, Lord Baltimore asserted his claim to the country on the west side of the river as a part of his grant, which extended to lat. 40° N., but excepted tracts then already occupied; and frequent incursions were made from Maryland with the view of driving away the settlers. At length William Penn, having obtained a grant of Pennsylvania, and being desirous of owning the land on the west bank of the Delaware to the sea, procured from the duke of York a release of all his title and claim to New Castle and 12 m. round it, and to the land between this tract and the sea. In Oct. 1682, he arrived at New Castle, and in the presence of the inhabitants produced his deeds and accepted the surrender of the territory. Lord Baltimore still asserted his claim, but Penn resisted it on the ground that at the time of the grant of Maryland the territory was occupied,

and in 1685 the lords of trade and plantations decided in Penn's favor. The conflicting claims, however, were subsequently adjusted by compromise. The tracts now constituting the state Penn called the "territories or 3 lower counties on the Delaware." For 20 years they were governed as a part of Pennsylvania, each county sending 6 delegates to the general assembly. In 1703 the territories obtained liberty to secede, and were ever afterward allowed a distinct assembly. The proprietary, however, until the commencement of the revolution retained all his rights, and the same governor uniformly presided over Pennsylvania and Delaware. Sheltered by the surrounding colonies, Delaware enjoyed an entire exemption from wars, except those in which as a part of the British empire she was obliged to participate. In the war with France which terminated in 1763, she was second to none in active zeal; and in the revolutionary war the Delaware regiment was one of the most efficient of the continental army. In 1776 the inhabitants declared themselves an independent state, and framed a constitution. In 1792 a second constitution was established, which with subsequent amendments still forms the fundamental law of the state. The federal constitution was ratified by Delaware, Dec. 7, 1787.

DELAWARE. I. A S. E. co. of N. Y., bounded N. W. by the E. branch of the Susquehanna, and S. W. by Delaware river, which separates it from Penn.; area, 1,550 sq. m.; pop. in 1855, 39,749. It is drained by the head streams of the Delaware, has a hilly surface, and a soil which in the valleys is extremely fertile. The productions in 1855 were 119,383 bushels of Indian corn, 416,659 of oats, 9,494 of wheat, 209,567 of potatoes, 103,896 tons of hay, and 4,026,575 lbs. of butter. There were 26 flour mills, 224 saw mills, 24 tanneries, 4 woollen factories, and 5 carding and fulling mills. Six newspapers were published in the county; there were 92 churches, and 314 school houses. The Delaware and Susquehanna rivers, from the former of which the county is named, are here navigable by boats, and are the channels through which vast quantities of lumber are annually exported. Capital, Delhi. II. A S. E. co. of Penn., bordering on Del., separated from N. J. on the S. E. by the Delaware river, and drained by a number of small streams; area, 108 sq. m.; pop. in 1850, 24,679. The surface in the S. E. part is generally level, but in other places is hilly. A large proportion of it is occupied as grazing land, and the markets of Philadelphia are supplied with milk, butter, and cheese mainly from the dairies in this county. The soil is not naturally fertile, but by the use of manures has been rendered extremely productive. The most important minerals are mica slate, extensively used for building, and gneiss. Whetstones are procured near Derby, and exported to nearly all parts of the union. The water power with which the county is abundantly supplied is employed in numerous manufactories of cotton and woollen, flour, saw, and paper mills, and other establishments. The agricultural productions in 1850 were 294,209 bushels of corn, 121,096 of wheat, 169,754 of oats, 108,508 of potatoes, 27,932 tons of hay, and 1,342,243 lbs. of butter. There were 58 churches, and 2,995 pupils in the public schools. The county was settled by Swedes in 1643, organized in 1789, and named from Delaware river. Capital, Media. III. A central co. of Ohio, traversed by the Scioto and Olentangy rivers, well supplied with water power; area, 478 sq. m.; pop. in 1850, 21,817. It has an even surface, a fertile soil, and in 1850 produced 774,289 bushels of corn, 44,523 of wheat, 142,992 of oats, 22,021 tons of hay, and 124,064 lbs. of wool. There were 45 churches, and 8,261 pupils attending public schools. At Delaware, the capital, are several excellent sulphur springs. IV. An E. co. of Ind., drained by White and Missinewa rivers, and consisting in great part of low marshy prairies, suitable for pastures; area, 400 sq. m.; pop. in 1850, 10,843. The surface is generally level, and the soil fertile. In 1850 the productions were 429,209 bushels of corn, 55,078 of wheat, 41,992 of oats, and 4,957 tons of hay. There were 15 churches, and 1,894 pupils attending public schools. The county was named from the Delaware Indians, who once owned the soil. Capital, Muncie. V. An E. co. of Iowa, well supplied with water and timber, and having a healthy climate, a fertile soil, and a rough hilly surface; area, 576 sq. m.; pop. in 1856, 8,099. In the same year it produced 117,700 bushels of wheat, 113,747 of oats, 342,271 of corn, 57,368 of potatoes, and 126,330 lbs. of butter. Capital, Delhi.

DELAWARE BAY. See DELAWARE.

DELAWARE COURT HOUSE, or DELAWARE, a post town and capital of Delaware co., Ohio; pop. in 1850, 2,074. It is pleasantly situated on rolling ground, on the right bank of Olentangy river, which is here crossed by a bridge. It is a handsome place, neatly built, and the seat of the Ohio Wesleyan university, established in 1845. A sulphur spring in the vicinity is much resorted to. Two newspapers are published in the town; there are 5 or 6 churches, and a branch of the state bank of Ohio.

DELAWARE RIVER (Indian name, *Makeriskitton*), a large river of the United States, formed by two small streams called the Oquago (or Coquago) and the Popacton, which rise on the western declivity of the Catskill mountains, N. Y., and unite on the boundary line between New York and Pennsylvania, near the N. E. angle of the latter. Flowing S. E., it separates those states for about 70 m., until it reaches Kittatinny (or Shawangunk) mountain, near Port Jervis. At this place it makes a sharp turn to the S. W., and forms the dividing line between New Jersey and Pennsylvania. At the N. extremity of Northampton co. it passes through a precipitous defile, formed by perpendicular rocks on either side 1,000 or 1,200

feet high, and known as the Delaware Water Gap. A few miles below Easton it turns again to the S. E., and after passing Trenton meets the tide water 132 m. from the sea. The stream now becomes much wider, and acquires sufficient depth for the passage of steamboats. Philadelphia, on the right bank, is the head of navigation for ships of the largest size. On the other side of the river are the towns of Burlington and Camden, the latter being just opposite Philadelphia. The channel is here about 1 m. wide, and divided by a small island. A number of other islands, none of them of great extent, occur in various parts of the stream. Bridges connect the opposite banks at Trenton and several other points. About 40 m. below Philadelphia the river discharges itself into Delaware bay, after a total course of 300 m. The Delaware and Hudson and the Morris canals connect the stream with the Hudson, and a canal from Easton to Bristol passes near its banks. The N. Y. and Erie railroad runs in the valley of the Delaware for a distance of nearly 90 m. The shad fisheries in the lower part of the river are very profitable. During the winter of 1851–'52 a solid bridge of ice formed in the channel at Philadelphia, an event which occurs only in seasons of excessive severity.

DELAWARES, called in their own language the LENAPES, one of the Algonquin tribes of American Indians, now established in the territory of Kansas, which occupied at the beginning of the 16th century the valley of the Delaware river and the banks of the Schuylkill. According to their traditions they were in past ages eminent for valor and wisdom, and held a prominent place in Indian history, exerting an authoritative influence from the Chesapeake to the Hudson. This claim seems to be recognized by the other tribes of their lineage, who apply to them the honorable title of grandfather. On the rise of the Iroquois power they lost their independence; and in the large assembly of tribes which concluded the treaty at Lancaster in 1744, the Iroquois denied the right of the Delawares to alienate their lands. The latter, being immediately ordered by their masters to remove to the banks of the Susquehanna, left for ever the region of their native Delaware. In 1751 they are found at Shamokin and Wyalusing on the Susquehanna, positions where they were exposed to the violence both of the Iroquis and of white emigrants. It was their misfortune to be regarded by the English as under French influence, an opinion which lost none of its force from the fact that many of the Delawares had adopted the principles of peace and non-resistance taught by Penn and Zinzendorf. The Iroquois were also offended by their neutrality, and because they applied themselves to agriculture and grazing, refusing to join in forays of plunder and murder, while the Indian and French war was raging on the frontier from Quebec to New Orleans. A tragical result at length followed. In 1781 nearly 400 Moravian Delawares, settled on the Muskingum, were plundered by a hostile Indian party, and ordered to remove to Sandusky, on Lake Erie. Being permitted to return in the next year, their movement was regarded as a hostile one by the British frontiersmen, who united and surprised the unresisting Moravians at Muskingum, and massacred nearly 100 of them. In a treaty at Fort Pitt, in 1778, the Delawares entered into terms of amity with the United States, granting power to march armies through their country on condition that a fort should be built for their protection. This was the origin of Fort McIntosh. In 1795 they were parties, with the Wyandots, Shawnees, Miamies, and other western tribes, to the general pacification of Fort Grenville. These relations were further strengthened by the treaties of Fort Wayne (1803) and Vincennes (1804); and the frontiers were not molested by their war parties till the primary movement of Tecumseh in 1811–'12. They did not long rest upon the Susquehanna, but gradually continued their migration westward, resuming their habits of war and hunting, and stopping for a time on the White Water river, in Indiana. Thence they crossed the Mississippi, and are now established on fertile tracts on the Kansas river, in the territory of that name. A portion of them went into Texas, where they have an excellent reputation as guides, hunters, and woodsmen. They possess 375,000 acres of land at the mouth of the Kansas river, and 3 times this amount at higher points on that river and its tributaries. Their number was returned in 1840 at 830; in 1850, at 1,500; and is now estimated at above 2,000. A considerable portion of them are cultivators of the soil, raise horses, cattle, and hogs, and dress in many respects in civilized costume. The United States hold in trust for them a school fund of $7,806, and a general fund of $915,375.

DELESSERT, BENJAMIN, a French financier and philanthropist, born in Lyons, Feb. 14, 1773, died in Paris, March 1, 1847. After completing his early education, he visited Edinburgh and London, and made the acquaintance of Adam Smith, Dugald Stewart, Playfair, and Watt. He served in Belgium as captain of artillery under Pichegru, but on the death of his eldest brother resigned his commission to assume the direction of his father's bank. In 1801 he established a sugar refinery at Passy, and he contributed much to the success of the manufacture of beet root sugar in France. Such was his reputation for skill and integrity, that before he was 30 he was appointed regent of the bank of France, which post he held for nearly half a century. He was a patron of savings banks, primary schools, houses of refuge, and other charitable institutions. He was an associate of the academy of sciences, and formed magnificent botanical and conchological collections; his herbal, which had been commenced for his sister by J. J. Rousseau, contains no less than 86,000 specimens of plants, 3,000 of which were previously unknown. His botanical collections are illustrated in the important work,

in which he was a collaborator with De Candolle, *Icones selectæ Plantarum* (2 vols. 4to., Paris, 1820–'46), and his conchological treasures were described in 1847 by Dr. Chenu. Beside his political speeches delivered in the chamber of deputies, where for years he occupied a seat among the conservative party, and his pamphlets on savings banks, he published a philosophical tract, *Le guide du bonheur*, which has been several times reprinted, and other writings.

DELFT, one of the oldest Dutch towns, in the province of South Holland, 8½ m. by rail from Rotterdam, on the small river Schie, and connected by canals and railways with the other principal towns of Holland; pop. about 18,000, of whom 6,000 are Catholics, and the remainder chiefly Protestants. It is intersected in all directions by canals, which are crossed by 69 bridges. The principal public buildings are the town hall; the palace or *prinsenhof*, originally the convent of St. Agatha, once the occasional residence of William I. of Orange, and the scene of his assassination (July 10, 1584), now converted into barracks; the new church, with a huge square tower and celebrated chimes, containing the mausoleum of William I., and the tombs of the Orange family, and of Hugo Grotius, who was born in Delft; the old church, distinguished by a leaning tower, containing the oldest organ in Holland, the monument of Admiral Van Tromp, and the tombs of Leeuwenhoeck, the naturalist, and other eminent citizens of Delft; two Roman Catholic churches, several other churches for various Protestant denominations, and a chapel for Jansenists. There are also a gymnasium and 17 other schools, an academy for civil engineers and industry, several associations for the promotion of art, science, and literature, and various benevolent institutions. Delft was formerly celebrated for its potteries (delft ware), but this manufacture is now almost entirely superseded by the superior articles made in England. The little earthenware now made here is of the coarser kind. Of the other manufactures, those of mathematical instruments are most renowned. Near the entrance of the town is the state arsenal of Holland, originally the Dutch East India house, to which a college for engineers is attached. Delft was almost entirely destroyed by fire in 1536, and again in 1654, when an explosion of the powder magazine reduced 500 houses to ashes, and killed 1,200 persons. But by being frequently rebuilt, the town was so much improved that Pepys in his diary (May 18, 1760) describes it as "a most sweet town, with bridges and rivers in every street." In 1797 the Delft religious association (*Christo sacrum*) was established here by members of the French reformed church, with the view of forming a union between all Christian sects, but is now almost extinct.—Delft is connected by a canal with its port, DELFT-HAVEN or DELFTSHAVEN, a small town on the right bank of the Meuse, 2 m. from Rotterdam, with 3,200 inhabitants, engaged in distilleries, herring and cod fisheries, and shipbuilding. Delft-Haven is celebrated in American history as the place where the pilgrim fathers embarked for Southampton, July 22, 1620.

DELFT WARE, a kind of pottery of clay, or clay mixed with sand, and covered with a white enamel, which gives to it the appearance of porcelain. The vessels composed of this preparation are first moulded, then slightly baked, in which state they readily receive the enamel, when a stronger heat is applied for the purpose of fusing the enamel uniformly and to complete the baking process. Sometimes this pottery is finely ornamented with painting. The more common and coarser kinds, however, better resist a sudden heat. The preparation of the enamel is an important part of the process in making delft ware, and various receipts are given for it. It should be made so opaque that the ware cannot be seen through it.

DELHI, or D'HILLI, formerly an administrative division of the N. W. provinces, British India, comprising the districts of Paniput, Rhotuk, Hurriana, Goorgaon, and Delhi; area, 6,274 sq. m.; pop. in 1853, 2,195,180. The district of Delhi lies on the W. bank of the Jumna, between lat. 28° 24′ and 28° 54′ N., long. 76° 49′ and 79° 29′ E.; area, 789 sq. m.; pop. 435,744, of whom 316,065 are Hindoos, and the rest mainly Mohammedans. The surface is rough in some parts, but not mountainous. The soil, like that of the 4 other districts, is naturally barren, but by means of works of irrigation a valuable extent of land has been made arable. More than ⅓ of the whole surface, however, is uncultivated. About 3,300 acres are devoted to cotton, yielding a crop of about 300,000 lbs., cleaned. The other principal productions are barley, pulse, and wheat. The climate is commonly dry; the temperature ranges from 56° in January to 92° in June, but at certain seasons the district is swept by hot winds of fearful intensity, accompanied by tornadoes and rain storms. In Jan. 1859, the Delhi division was detached from the N.W. provinces, and formed, with the Punjaub, the Trans-Sutlej and Cis-Sutlej states, into a lieutenant-governorship called the Punjaub and its dependencies.—DELHI, the capital of the above district, and the Mohammedan metropolis of India, is built principally on a short offset of the Jumna, about a mile from the right bank of the main stream, 115 m. N. N. W. from Agra, 40 m. S. W. from Meerut, and 830 m. N. W. from Calcutta; lat. 28° 39′ N., long. 77° 18′ W.; pop. in 1853, 152,406, of whom 76,372 were returned as Hindoos and 76,034 as Mohammedans, no account being given of the Christian inhabitants. The city is 7 m. in circumference, and enclosed, except on part of the water front, by a wall of red sandstone, with bastions, martello towers, and 11 gates, 4 of which face the river. There is also a dry ditch 20 feet wide, and on the island formed by the Jumna and its offset stands the old fort of Selimgurh, whence a bridge of boats crosses the main stream. The defences were built by Shah Jehan and improved by the British. Delhi con-

tains many good brick and stone houses, and, for an Asiatic city, is remarkably clean. The Chandnee Chowk, or silversmiths' street, the main thoroughfare, is 150 feet wide, lined with gay bazaars, and traversed by a canal bordered with trees. At its head, abutting on the river and defended by a broad moat, stands the imperial palace of Shah Jehan, once of almost unparalleled magnificence, but now filthy and neglected. It is a collection of buildings surrounded by a wall 40 feet high, and ¾ of a mile in circuit, including a private royal mosque, large gardens, and apartments for several thousand persons. Here, too, are the white marble council chamber with its 4 cupolas, and the public audience hall in which stood the famous "peacock throne," formed entirely of gold and jewels, and valued at $30,000,000. The jumma musjid, or chief mosque, in Mohammedan eyes the wonder of the world, built by Shah Jehan in 6 years, stands on a paved platform, 450 feet square, on a rocky height near the centre of the city. It is approached by broad stone steps, and makes one side of a quadrangle, the other sides of which are formed by pavilions and arcades. It is 261 feet long, lined and faced with white marble, surmounted by 3 domes of the same material striped with black, and having at each end of the front a high minaret. Scattered through and around the city there are more than 40 other mosques, some mean Hindoo temples, and tombs of the emperors and Mussulman saints. Nine miles S. is the Cuttub (Kuttub or Kutb) Minar, 242 feet high, said to be the tallest column in the world, and close to it is the emperor's country residence. Among the European buildings are the British residency, St. James's and several missionary churches, a bank, a lunatic asylum, the courts of justice, and a government college attended chiefly by native students. The last is managed by a council of Europeans and natives, has an income of about $18,750, and is divided into 4 departments: English, Arabic, Persian, and Sanscrit. There are, moreover, in and near the city, about 300 schools, and a newspaper office. There are 2 arsenals, one outside the walls, the other within. The latter, prior to 1857, was the most important in India, and contained 300 guns and mortars, 20,000 stand of arms, and 200,000 shot and shells, beside gunpowder and other warlike stores. The Jumna is impregnated with natron, but the city is supplied with water by a canal 70 m. long, built under Shah Jehan and restored by the British. Another, called the Doab canal, for irrigation, built by the same emperor, fed by the Jumna, and joining that river again near here after a course of 135 m., was also repaired by the British in 1830. Delhi has manufactories of cotton, indigo, and shawls. The fabrics of Cashmere are brought here to be embroidered with gold and silk, and an active trade in horses, fruit, precious stones, &c., is kept up with Cashmere and Cabool. The great East India railway, when completed, will connect the imperial city with Calcutta and Lahore, and a tram road has been projected to unite it with Futtehghur.

—If we are to trust Abul Fazl, no less than 7 cities have occupied the site of Delhi. The first was Indraprast'ha, or Indraput, where the Hindoo rajahs had their capital at least as early as the 10th century. In 1193 it was captured by Mohammed of Ghor; and Cuttub-ud-deen, a lieutenant of the victor, founded here a dynasty known to Europeans as the Patan or Afghan, and to oriental historians as that of the "slaves of the sultan of Ghor." The house of Cuttub was overthrown in 1288 by the Afghan Ghiljies or Khiljis, who were in turn displaced by the Togluck princes in 1321. In 1398 the city was desolated by Tamerlane; in 1450 it was acquired by the Afghan tribe of Lodi; and in 1526 it was seized by the renowned Baber, the founder of the long line of Mogul emperors. With these changes of the sceptre the empire alternately waxed and waned, at one time (1340) embracing almost the whole peninsula, at another (1398) restricted to a few miles around the capital. Under the Moguls it recovered more than half its former possessions. Akbar removed the throne to Agra, but Shah Jehan in 1631 built the present city close to old Delhi, and made it the royal residence. The Mohammedans still call it Shahjehanabad, the "city of the king of the world." Nadir Shah, the Persian usurper, captured it in 1739, massacred the inhabitants from the dawn of light till day was far spent, and bore away plunder to the value of nearly $100,000,000, including the famous peacock throne and the great koh-i-noor diamond, now in the possession of Queen Victoria. From this time dismemberment rapidly went on. The Great Mogul lost all but the shadow of sovereignty, and at last fell into the hands of the Mahrattas, who were defeated near Delhi, Sept. 11, 1803, with dreadful slaughter, by the British under Lord Lake. The titular emperor was released from captivity, a pension of $500,000 a year was assigned him, a resident was appointed at his court, and the British exercised the government in his name. In 1827 the empty show of power was taken from him, $250,000 were added to his allowance, and though still revered by Mohammedans as the descendant of Timour, his sway was thenceforth confined to the 12,000 members of his family who filled his palace and swallowed up his pension. At the time of the revolt in 1857, the garrison of Delhi consisted of the 38th, 54th, and 74th regiments of native infantry, and one battalion of native artillery, the only European soldiers being the 48 officers by whom this force was commanded. On May 10 three regiments mutinied at Meerut and marched off to Delhi, where they arrived the next day. The garrison, after a show of resistance, joined their ranks, and in a short time the whole populace was in arms. Some of the officers and civilians escaped to Meerut, Umballa, Kurnaul, and other places, but a large number of Europeans of both sexes were butchered with refined cruelty. The arsenal was held by Lieut. Willoughby and

8 Europeans, who stoutly defended it against several hundred sepoys until their position became desperate, and then blew up the magazine. Hundreds of sepoys—some say 1,000—were killed by the explosion, but the brave young officer in command, and some of his companions, escaped for the time with severe injuries. Meanwhile the aged king took command of the city, appointed officers, and resumed the imperial state to which he had long been a stranger. News of this disaster was telegraphed to Umballa the same day, and the British lost no time in preparing for the reconquest of a city on which the fate of India was thought to hang. Three brigades were ordered to march from Umballa and Meerut, under Brigadiers Wilson, Halifax, and Jones; and Gen. Anson, the commander-in-chief, left Simla to place himself at their head, but on reaching Kurnaul died of cholera, May 27. The command now devolved on Sir Henry Barnard, who, after one or two victories, appeared before Delhi, June 8. The rebels were found posted on a rocky ridge 1,500 yards from the north wall of the city, but by a rapid movement Sir Henry attacked them in flank, swept their position, and captured 26 guns. The British camp was then pitched about 1½ m. from the north wall, screened by the ridge, the left resting on the river, and the rear on a canal. For many days it required all the efforts of the besiegers to hold their own ground. They were too weak either to risk an assault or to cut off the reënforcements which the mutineers continued to receive from all parts of Bengal. Moreover, they were yet without heavy artillery, while the rebels had nearly 200 guns, which they managed with a skill equal if not superior to that of the besiegers. For 2 months a day seldom passed without sorties, in which both parties suffered severely. June 12, the insurgents attacked both flanks, and were twice repulsed. On the 17th they were gallantly dislodged from an unfinished battery near the Subzee Mundee suburb in advance of the besiegers' right; on the 19th a serious attack was made on the camp from the rear; and on the 23d, the centenary of the battle of Plassey, a still harder contest was fought on the right, lasting all day, and signalized by the bravery of the "guides," a native corps of picked men, mostly Punjaubees, who on this occasion fought uninterruptedly for 15 hours without food. On July 1, at sunset, an action, which lasted 22 hours, began on the extreme right, where 300 Europeans and guides held at bay throughout the night a force of nearly 5,000 men. On the 5th Gen. Barnard died of cholera, and was succeeded by Gen. Reed, who before the end of the month resigned on account of sickness to Gen. Archdale Wilson. On the 31st an immense force began a general attack on the advanced posts of the British, assailing them from two quarters at once with unusual skill and determination. The battle raged day and night until Aug. 2 at noon, when the rebels withdrew, leaving the field heaped with their dead. On the 24th, 7,000 mutineers left the city to intercept the siege battery, then on the way from Ferozepoor, and were immediately pursued by Gen. Nicholson, who had joined Wilson on the 8th. He overtook them at Nujuffghur, and routed them so completely, that they fled back to Delhi. By Sept. 8 all the reënforcements had arrived, and preparations were made to besiege the city in form. The force at Gen. Wilson's disposal amounted to 9,866 effective men, without counting the Cashmere contingent, 2,200 strong, some hundred men under the rajahs of Jheend and Putialah, and about 3,000 in hospital. It embraced Europeans (about ⅓), Sikhs, Gorkhas, Punjaubees, Beloochees, and Afghans, and was distributed as follows: infantry 6,089, cavalry 1,705, artillery and engineers 2,072. The mutineers are supposed to have numbered 14,000, beside cavalry. On the 11th the new battery opened fire, and a furious bombardment was kept up day and night by 44 heavy guns and many of small calibre. On the night of the 13th two breaches, one near the Cashmere and the other near the Water bastion, were found practicable. The storming party was now arranged in 4 columns. The 1st, of 1,000 men under Nicholson, was to assault the main breach, and escalade the face of the Cashmere bastion; the 2d, of 850 men under Brigadier Jones, was to move against the Water bastion; the 3d, of 950 under Col. Campbell, preceded by an explosion party, was to force the Cashmere gate; and the 4th, consisting mainly of natives, led by Major Reid, was to assail the enemy's strong position in the Kissengunje and Pahareepoor suburbs. The reserve, 1,300 strong, had orders to await the result of the first attack. At 4 o'clock on the morning of the 14th the troops left the camp, and concealed themselves near some advanced posts on the left until the signal for assault was given by Nicholson. On emerging upon open ground they were met by fearful volleys of musketry, thinning their ranks so fast that for full 10 minutes it was impossible to plant the ladders in the ditch. But the columns never wavered; they soon mounted the scarp, and with a ringing cheer the 1st and 2d divisions sprang upon the breaches, and carried them at the point of the bayonet. Once within the walls, they fought their way inch by inch along the ramparts, occupying the bastions, and turning the guns against the city. They secured the Moree and Cabool gates, but were beaten back from the W. wall with the loss of the gallant Nicholson. In the mean time Lieuts. Home and Salkeld, with 3 non-commissioned officers and a few native sappers, undertook the dangerous task of blowing up the Cashmere gate. In full daylight they marched boldly up through a shower of balls, arranged the powder bags in the face of a murderous discharge of musketry through an open wicket, and fired the train. The gate fell with a crash, but Lieut. Salkeld, a sergeant, a corporal, and 2 natives were killed. The 3d column now dashed forward, entered the city at 10 o'clock, just as the 1st and 2d gained the breaches, and pushed on

toward the jumma musjid, but was beaten back with great loss to the Cashmere gate, where the reserve came to its support. The 4th column sustained a defeat in the suburbs, and retreated to the camp. When night closed, the British found themselves in possession of the N. ramparts, and of several strong posts in that part of the city, and at dawn on the 15th commenced the work of dislodging the rebels from the loopholed houses and public buildings. The arsenal, which Lieut. Willoughby's exploit had but half destroyed, was stormed on the 16th, and its guns were turned against the palace. The Burn bastion was surprised on the same evening; the great mosque was entered on the 17th, and by the afternoon of the 20th, after a desperate street conflict of nearly 7 days, the British were again masters of all Delhi. No quarter was given, even to the sick and wounded. Women and children were invariably spared, but the conquerors did not always discriminate between armed rebels and peaceable inhabitants. Large bodies, however, made their escape while the fighting was going on, and among them was the ex-king, who took refuge in the suburban palace near the Cuttub Minar. The next day he surrendered to Capt. Hodson, on promise of his life, and on the 22d 3 of the royal princes were captured at the tomb of Humayoun, and immediately shot. The trial of the ex-king, now 90 years old, commenced Jan. 27, 1858, in his own palace. He was found guilty of complicity in the mutiny and its attendant atrocities, was condemned to transportation for life, and in Dec. 1858, was removed to the Cape of Good Hope. The British losses in this memorable siege were 3,837 killed, wounded, and missing. On Sept. 14 the casualties were 8 officers and 265 men killed, 52 officers and 822 men wounded. Of the number of insurgents who perished no authentic record could be obtained, but it must have been great. Over 1,500 are supposed to have fallen on the day of assault.

DELILLE, Jacques, a French poet, born at Aigues-Perse, Auvergne, June 22, 1738, died in Paris, May 1, 1813. He was a natural son of a lawyer named Montanier, and his only fortune was a good education and an income of 300 francs a year. He became known in 1769, by his translation of Virgil's Georgics, which won the highest praise from competent critics. Louis Racine, who had urged him to the work, gave it unlimited approbation; and Voltaire insisted upon the title of academician being at once conferred upon him. This distinction he received 2 years later, and he was soon afterward appointed professor of Latin poetry in the college of France. In 1782, on the publication of his original poem, *Les jardins*, he was presented through the favor of Count d'Artois with an abbey, with a yearly income of 30,000 livres. In 1784 he visited Greece and Turkey in company with Choiseul Gouffier, the French ambassador to Constantinople. The revolution deprived him of his office and the greater part of his income. He was arrested during the reign of terror, but saved by the interposition of Chaumette. For the celebration of the *Fête de l'être suprême*, he wrote, at the request of Robespierre, an ode in praise of the immortality of the soul. In 1795 he completed his translation of Virgil's Æneid, and subsequently visited Switzerland, Germany, and England. On his return to France in 1802 he was reinstated in his professorship, resumed his literary pursuits, and published successively the various poems which he had partly prepared during his travels: *L'homme des champs* (1800); *La pitié*, a touching poem on the victims of the revolution (1803); his translation of Milton's "Paradise Lost" (1805); *L'Imagination* (1806); *Les trois règnes de la nature*, with annotations by Cuvier (1809); *La conversation* (1812). His later years, during which he became blind, were spent quietly at Nanterre. His last composition, which, however, he did not live to complete, was entitled *La vieillesse*, and he used to say jestingly that he was "full of his subject." His translation of Pope's "Essay on Man," and his poem *Le départ d'Éden*, were published after his death. The most complete edition of his works was published by Michaud (16 vols. 8vo., 1824–'25).

DELINIERS, Jacques Antoine Marie, viceroy of Buenos Ayres, born at Niort in France, Feb. 6, 1756, shot at Buenos Ayres in 1810. In his earlier years he served in the Spanish navy, and having attained the rank of captain he was sent during the war with Great Britain on a mission to South America. In June, 1806, an English squadron made its appearance before Montevideo, and landed 1,100 men under Gen. Beresford. The Spanish army which opposed them was routed, and on July 2 the English took possession of the city. Deliniers was then at Montevideo. Having received intelligence of what had taken place, he assembled the forces at his command and marched against the English, whom, after some hard fighting, he compelled to capitulate, leaving to the conquerors 1,600 muskets, 26 cannon, and 4 howitzers. For this exploit, in accordance with the wish of the people, he was elevated to the viceroyalty of Buenos Ayres. On July 1, 1808, he fought an obstinate battle with the English in the vicinity of that city; but although the loss of the Spaniards is said to have been less than that of the English, the former were compelled to retire within the walls. The English immediately laid siege to the city, but were unable to make themselves masters of it, and were at last obliged to retire, having suffered great loss. Deliniers shortly afterward compelled them to make a treaty by which they agreed to abandon Montevideo, and the whole country in the neighborhood of the La Plata, within 2 months. This achievement gave him great reputation, and, in return for it, he was appointed brigadier-general by the king of Spain. He was now at the height of his popularity, but the people of Buenos Ayres were anxious for independence, and Deliniers, having espoused the cause of the king, excited a powerful party

against him, and found himself under the necessity of retiring into exile. It was not long, however, before he recovered his power, and he was in possession of it when a new viceroy, Don Balthasar de Cisneros, was sent out from Spain to replace him. He at the same time received the title of count of Buenos Ayres, but was ordered to return to Europe. This he refused to do, and retired to Mendoza. The deposition of Deliniers produced a revolution which compelled Cisneros to abdicate. But when Deliniers with 2,000 men attempted to reëstablish the royal authority, he was met by the revolutionists, his army dispersed, and he himself taken prisoner. He was brought to Buenos Ayres, where he was shot with several other royalist leaders, by order of the revolutionary junta.

DELIRIUM TREMENS, Delirium Ebriositatis, Mania a Potu, a disease caused by the abuse of spirituous liquors, and characterized by tremor, sleeplessness, and delirium. It is remarkable that a disease so well marked and so easily recognized as delirium tremens should up to the early part of the present century have been confounded with inflammation of the membranes of the brain, and that, thus misled by a name, most physicians bled, blistered, and mercurialized their patients, thus adding vastly to the mortality of a complaint already sufficiently fatal. Delirium tremens sometimes makes its appearance in consequence of a single debauch; commonly it is the result of protracted or long continued intemperance. Occasionally, where the indulgence is very excessive, the attack occurs while the patient still continues his potations; more generally it is the result of some cause by which they are temporarily interrupted; the patient's stomach gives out and refuses the accustomed draught, he receives a hurt, or he is affected by some of the ordinary causes of illness. If the patient be now noticed, he will be found to be nervous and uneasy; he is startled by any sudden noise, the opening of a door, the entrance of a visitor; he is restless; the hands and tongue are tremulous; he complains of inability to sleep, and if he dozes for a moment he is awakened by frightful dreams; with all this, his skin is commonly cool and soft, his pulse slow, and his tongue moist. Soon delirium manifests itself; if questioned, the patient often answers rightly enough, but if left to himself he begins to talk or mutter; he is surrounded by frightful or loathsome animals; he is pursued by some one who has a design upon his life; he has terrible and ghastly visions. Though most commonly of a frightful or terrifying character, the delirium is not invariably so; occasionally the appearances are droll or ludicrous, and the patient seems amused by them. He is rarely dangerous; his predominant emotion is fear; but in the effort to escape an imaginary enemy, he may be guilty of a murderous assault, or more probably of taking his own life. The delirium continues until the patient dies exhausted, or until he sinks into a sleep from which he awakes comparatively rational. When the strength of the patient has not been seriously impaired by long continued excesses, delirium tremens is rarely fatal; but those whose constitutions have been broken down by a long course of intemperance frequently succumb. In such cases death is often sudden; the patient rises for some trivial purpose, and falls in a faint from which he never recovers. At other times, after passing many nights without sleep, he sinks into a state of coma, which terminates in death. It must be borne in mind that the same habits which cause repeated attacks of delirium cause likewise organic affections of the viscera, more particularly of the liver and kidneys, and that these seriously influence the result of each new attack.—*Treatment.* When nausea is present, and the tongue large and coated, it is well to commence the treatment by an emetic or an emeto-purgative; in mild cases, and when the strength of the patient will admit, it will be sufficient to keep him walking with a careful attendant until fatigue induces a tendency to sleep. In severer cases, opium is the article mainly relied on by practitioners, and in most instances it will not disappoint their expectations; still there is a class of cases rebellious to its influence, whatever dose may be given. Sometimes here the inhalation of chloroform comes to our aid, and accomplishes that which opium unassisted could not do; in other cases the use of small doses of tartar emetic and laudanum produces the happiest effects. It is necessary to maintain the patient's strength by the administration of suitable nourishment, and in some cases the use of stimulants will be found not only beneficial but indispensable.

DEL NORTE, a N. W. co. of Cal., bordering on the Pacific ocean and Oregon. A great part of the surface is mountainous, and the coast range runs along its border. It was formed in Feb. 1857, from the N. part of Klamath co., to which it is attached for representative purposes. Capital, Crescent City.

DELOLME, Jean Louis, author of a celebrated work on the English constitution, born at Geneva in 1740, died in Switzerland, July 16, 1806. Having published a pamphlet which gave umbrage to the authorities of his native city, in which he had been established as a lawyer, Delolme repaired to England. Here he found in the study of British institutions an ample field for his observant nature, and at the same time a congenial political atmosphere. He was the author of various works and essays on political affairs, but his fame rests upon his book on the English constitution. First written in French and published at Amsterdam in 1771, it met with a favorable reception, which induced Delolme to enlarge and improve it, and to publish a new edition in English, which appeared in 1772. The demand for it became so great that 4 new editions were sold within 20 years, and a German translation appeared at Altona in 1784. A new edition, with life and notes by J. Macgregor, M. P., was published in 1853.

DELOS, or Delus, now Dili or Sdilli, the

smallest island of the Cyclades, called also by the ancients Asteria, Ortygia, or Chlamydia. One of their legends, probably alluding to its origin by a volcanic eruption, represents it as having risen from the waves of the sea at a stroke of the trident of Neptune, and floated on the Ægæan, until it was moored to its bottom with adamantine chains by Jupiter, in order that it might become a place of refuge for Latona, who was delivered there, on a desert rock and under a shady tree, of Apollo and Diana, hence called Delius and Delia. To them the island was sacred, and in accordance with a vow of Latona a temple was erected by Erysichthon, son of Cecrops, at the foot of Mount Cynthus, which in due time was enriched by the gifts of nations, and remained unshaken by the earthquakes that often desolated neighboring islands. The oracle of Apollo, who gave responses here in summer, and at Patara in Lycia in winter, was regarded as the most distinct and trustworthy. Delian festivals were held here every 4 years; the Athenians sent there yearly their Theoria with choruses and dances. Latona had also her temple. Delos was colonized by the Ionians, became the centre of splendid festivals in honor of Apollo, and was ruled by kings, who at the same time performed the functions of priests. In later times it became dependent upon the Athenians, who performed there 2 purifications, first under Pisistratus, and secondly in the 6th year of the Peloponnesian war (426 B. C., as described in the 3d book of Thucydides), by removing the tombs and dead bodies to a neighboring island, and who also enacted a law to guard the sacred ground from the pollution of births and deaths. Its towns, having no walls, were guarded by their sanctity; its temple and immense treasures were untouched by the Persians in their invasion; and during the following wars it became the seat of the common treasury of the Grecian states. When this was removed to Athens, Delos decayed, but was still remarkable for commerce; and after the destruction of Corinth by the Romans (146 B. C.), was the chief emporium of the slave trade, and a flourishing seat of art. The city and temple were plundered and destroyed by Menophanes, general of Mithridates, king of Pontus, and the women and children sent as slaves to Asia. The remains of the splendid ancient buildings were at a later period carried away by the Venetians and Byzantines; but a few broken pillars and architraves are still to be seen on the almost desert island, whither shepherds from the neighboring islands transport their flocks, its climate being regarded as unhealthy for inhabitation.

DELPHI, or Delphos (Gr. ὁι Δελφοι), a small town of ancient Phocis, of high importance in the history of Greece as the seat of the oracle of Apollo. It was built in the form of an amphitheatre, on the steep S. W. extremity of Mount Parnassus, in a secluded mountain region, in the midst of wild peaks, rocks, and cliffs. Its name had its origin, according to the legends of Greece, either from Delphos the son of Apollo, or from a dolphin (δελφιν, or δελφις), in the form of which Apollo rushed into the sea, after having killed the dragon Pytho, and determined on the erection of a temple on the spot. Boarding a Cretan vessel, he made it pass by the place of its destination, Pylos, and entered the harbor of Cirrha, where the Cretans on landing were again struck by the appearance of the god as a beautiful youth, and with songs and hymns followed him to serve as his priests at Delphi, which they founded. The first sanctuary of Apollo was a rude shelter of laurel boughs, soon replaced by a temple which stood 700 years, and was burned in 548 B. C. The Amphictyons contracted with the rich Athenian Alcmæonidæ for its rebuilding, who did more than they promised, making the front of the splendid edifice of pure Parian marble instead of common stone. The cold stream of the Castalian spring flowed by it, as it also did by the temples of Latona, Diana, and Minerva. It enclosed the cavern Pythium, containing a fissure, out of which arose mephitic vapors of intoxicating and convulsing power. This was discovered by a shepherd, who, tending his goats at the foot of Mount Parnassus, and following them to the brink of the chasm, fell into prophetic ecstasy. It was above the chasm that the high tripod, covered with laurels, was fixed, on which the Pythia or priestess of the god was placed, after having bathed in the Castalian spring, and wreathed her hair with a garland of laurel. She was convulsed to ecstasy, sometimes even to fatal frenzy, by the suffocating exhalations, and by chewing the leaves of a laurel branch which she held in her hand; the color of her face changing, her limbs shivering, her hair bristling, her eyes beaming, and her lips foaming, she uttered wild groans and howlings, as well as single confused words and sounds. In the earlier times these were carefully collected, arranged in verse, usually in ambiguous phrases, and rendered in writing as the divine answers. The Pythia, who often fell a victim to the excitement of her office, was bound for life and to the strictest chastity. At first only poor young girls were selected for the service, but afterward women of the age of 50 at least, and natives of Delphi. The management of the temple of Delphi, and especially of its treasury, which was enriched by the donations of those consulting the god, by the tithes of the spoils of the conquered, by consecrated presents, and the regular deposits of states and individuals, was intrusted to the Amphictyons, or the deputies of the surrounding cities and states who assembled there; but the oracle was ruled by the priests, natives of the town, or rather under the influence of an aristocracy of its inhabitants, who were all regarded as the sacred family of Apollo, and delighted in continual sacrifices, festivals, feasts, and processions, as well as in the Pythian games, which were held in the plain between Delphi and Cirrha. The place was believed to be the centre of the earth, and indeed was called its

navel, two eagles sent by Jupiter from east and west having met there. The influence of Delphi through the oracle on the affairs of Greece and other nations was immense. Its treasures, monuments, and statues, particularly those of the temple of Apollo, were prodigious in number, value, and splendor. There could be seen, beside the countless statues of gods, demigods, and illustrious men, the extravagant gifts of Crœsus, king of Lydia, the portico with the inscriptions of the 7 sages, Persian bucklers from the battle of Marathon, the beaks of Persian ships taken in naval victories, the shields of the invading Gauls, an image of Homer, the grave of Neoptolemus, son of Achilles, the chair of Pindar, with many paintings and other works of art. These treasures tempted the avarice of Xerxes, whose troops were frightened away by skilful miracles, as were afterward the invading Gauls; many of them, however, were taken and wasted by the Phocians in their wars against the Amphictyons; they were borrowed by Sylla, who could not be awed by miracles, and plundered by Nero. The decayed place was still further stripped by Constantine the Great, and Julian the Apostate could as little restore its splendor as he could the worship of the ancient gods.

DELPHIN, the name applied to a celebrated edition of the Latin classics, which was prepared in the reign of Louis XIV., by 39 of the best scholars of the time, for the use of the dauphin (*in usum Delphini*).

DELPHINIUM, the name of an extensive genus of annual or perennial herbaceous plants belonging to the natural order of *ranunculaceæ*. They have handsome irregular flowers, resembling somewhat the fanciful figures of the dolphin or the spurs of larks, and are commonly known as larkspurs. The genus is nearly allied to the aconites. The seeds, especially of *D. staphisagria* (stavesacre) and *D. consolida* (branching larkspur), are powerfully cathartic, and owing to the violence of their operation are seldom given internally; they are, however, employed in destroying vermin. The extract (*delphinia*) has recently been used in tic douloureux, paralysis, and rheumatism. The blossoms of the delphiniums are very showy, and in some sorts they are even extremely rich and magnificent. Those known as the rocket larkspurs have elegantly colored flowers, though they are apt to exhibit too light and less showy tints. The double kinds of these are very attractive to the eye in early summer. Their seeds are sown in finely pulverized and rich soil in the autumn, either in beds, in patches, or in single rows, as fancy or taste may dictate, and the young plants thinned out when it is necessary. If allowed to stand too close together, the flower spikes are not so well developed. Sometimes they are used to succeed the blooming of hyacinths, and are accordingly sown in or near hyacinth beds. The interstices of tulip beds are sometimes sown with them in the same way; and thus the period of the fading of the flowers of the bulbs is enlivened by the spikes of the larkspurs bearing their hyacinth-like blooms. The few weeks previous to the proper time for taking up the bulbs suffice to exhaust the beauty of the larkspurs, so that they can be removed together. The perennial delphiniums are conspicuous for size and altitude. They vary, however, in both these particulars. Some grow from 5 to 6 feet high in a few weeks, having spikes of coarse blue or pale blue flowers. Others are more supine, have weaker flower stems, and a more divided and more graceful and delicate foliage. The blossoms of such are proportionably more beautiful, varying from the intensest blue or azure to a paler color, and so shading off by degrees to a pearly or opalescent tint. Cultivation has produced many extraordinary and double sorts, of which the *D. grandiflorum*, or Chinese, as it is sometimes called, and Buck's seedling are among the finest. These perennials are, however, herbaceous, all dying down to the root and rising again with strong shoots in the next year. From a singular resemblance of the inner petals, especially in the single flowers, to the body of a bee, they have been called bee larkspurs, the pubescence accompanying them helping the illusion by its seeming to be hairs. The species native in the United States are *D. exaltatum* (Mx.), with a stem from 2 to 5 feet high and purplish blue flowers, occurring in Pennsylvania; *D. tricorne* (Mx.), a pretty species of a foot high, seen in Ohio; and *D. azureum* (Mx.), a characteristic species in Iowa and Minnesota. One other is becoming naturalized, *D. consolida* (Linn.), having escaped from grain fields and appearing on the sides of the roads, like many other foreign species introduced by seeds from abroad, either for the garden or in field husbandry. A splendid scarlet-flowered delphinium was discovered by Dr. Parry in 1850, on the mountains east of San Diego. It is *D. coccineum* (Torrey, in "Mexican Boundary Survey"). Another scarlet-flowered species is known as *D. nudicante*. Both are deemed likely to become great acquisitions to the gardens.

DELTA, the name given to the triangular alluvial region included between the mouths of the Nile, from its resemblance in form to the Greek letter of this name, Δ. The term afterward came to be applied in general to similar alluvial formations at the mouths of large rivers, whatever might be their shape.

DELTA, the southernmost co. of the upper peninsula of Michigan, washed by Lake Michigan and by Green Bay; area, about 3,500 sq. m. The Menomonee river on the S. W. separates it from Wisconsin. It has a hilly, well wooded surface, and contains abundance of limestone and sandstone. The census of 1850 gives no information respecting this county, which was then but partially organized. It was probably named from its triangular shape.

DELUC, Jean André, a Swiss natural philosopher, born in Geneva, Feb. 8, 1727, died in Windsor, near London, Nov. 7, 1817. His

father, an author of considerable merit, was able to give him an excellent education, though he devoted him to commercial pursuits, in which the first half of his life was spent. During the numerous journeys which his business required him to make into the neighboring countries, he made, with the assistance of his brother, Guillaume Antoine, a fine collection of objects of natural history. In 1773, obliged by commercial misfortune to leave his native city, he went to England, was elected a fellow of the royal society of London, and was appointed reader to the queen; this situation he held for 44 years, in the latter part of his life making several tours in central Europe, passing 6 years in Germany, and after his return in 1804 making a geological tour in England; he received at Göttingen the appointment of honorary professor of geology in that university, though he never entered upon its duties; he was also a corresponding member of the French academy, and fellow of several other scientific associations. His principal writings treat of geology and meteorology; his first important work in the order of publication was *Recherches sur les modifications de l'atmosphère* (2 vols. 8vo., Geneva, 1772), which contains many valuable suggestions on the applications of barometers, thermometers, and hygrometers to practical purposes; he substituted mercury for spirits of wine in Réaumur's thermometer, and invented a portable barometer, establishing correct rules for determining by this instrument the height of mountains and the depth of mines; other papers on subjects connected with meteorology are scattered through the "Philosophical Transactions" from 1771 to 1792. He inherited a great veneration for the Holy Scriptures from his father, who had written much in refutation of the doctrines of Mandeville and other sceptical authors, and his religious fervor is manifest in all his works, contrasting strikingly with the prevailing infidel spirit of the age. In 1778–'80 he published the *Lettres physiques et morales sur l'histoire de la terre* (6 vols. 8vo., La Haye); this work treats particularly on the comparatively recent origin of the present continents and their mountains, and the difficulty of carrying back this origin to a period more remote than that assigned by the Mosaic chronology to the flood. Though all his conclusions are not now admitted in geology, he extended the limits of this science, and established many important points by his experiments in various branches of natural philosophy connected with it. His reverence for the Bible led him to explain any apparent contradiction between geological phenomena and the Mosaic account of creation; he considers the 6 days of Genesis as so many periods of immense and indefinite duration preceding the epoch of the actual condition of the globe, and attributes the deluge to the filling up of cavities supposed to have been left void in the earth's crust; the work is written in a truly religious spirit, and abounds in noble thoughts and interesting observations on men and manners. In his *Traité élémentaire de géologie* (8vo., Paris, 1809), he opposes the system of Hutton and Playfair, which attributes the changes in the earth's structure to the action of fire, and advocates the agency of water, and the lesser antiquity of the present state of the continents. Cuvier ranks him among the first geologists of his age. He contributed many papers to the *Journal de physique*, the *Journal des mines*, and the "Philosophical Magazine," on mineralogy, geology, and electricity; he separated the chemical from the electrical effects of the voltaic pile, and constructed an ingenious but incomplete instrument, the dry electric column, for measuring the electricity of the air. Some of his theories are not a little fanciful, and he strenuously opposed the discovery of the chemical composition of water; still his meteorological experiments on heat and moisture are of great value. He published also several volumes of his geological travels in England, and northern and central Europe, and works on the Baconian philosophy, the religious education of children, and on Christianity.—Guillaume Antoine, brother of the preceding, born in 1729, died in Geneva, Jan. 26, 1812. He travelled extensively, visiting Vesuvius and Etna in 1756–'57, making fine collections of volcanic products, fossil shells, and other objects of natural history; he was a close observer, exact reasoner, and clear and vigorous writer. His papers on mineralogy and geology may be found in the *Journal de physique*, 1798 to 1804; *Bibliothèque Britannique*, 1801 to 1809; and *Mercure de France*, 1806–'7. He was exceedingly fond of music, and an enthusiastic collector of coins, of which he had a fine cabinet.

DELUGE, an overflow of water, flooding the land, commonly applied to designate the Noachian flood of the Scriptures. This great natural phenomenon is described in the first book of Moses as occurring, as ordinarily calculated, in the 1656th year after the creation, and the 600th year of the life of Noah. A similar catastrophe is also recorded in the legends and traditions of almost all races upon the earth; and in most instances the descriptions, though sometimes in an allegorical form, so closely resemble the particulars of the account given by Moses, that they have been generally regarded as referring to the same great event. Among the nations of eastern and southern Asia, with whom the modes of life are least changed from those of remote antiquity, these traditions have been handed down from the period of their earliest histories. The Chinese have been understood to refer to it as the great event which divided the race of men into the higher and lower ages. Davis, however, in his work on the Chinese, attaches less importance to the traditional effects of their deluge, and suggests that from their own account of it the flood may have been but an overflow of the waters of the great Yellow river, which by their inundation might now sweep over extensive and thickly populated plains. But in the fanciful picturing of the Hindoo tradition of the god Vishnu meeting and

warning the prince Satyavarata, and furnishing him with a large vessel, in which the prince with 7 Nishis and their wives were saved, we appear to recognize the same event which occurred to the Jewish race, the identity made still more positive by the same narrative of what afterward happened to the prince and his sons. The Parsees in the sacred books of the Persians preserve the record of a universal flood of waters brought upon man for the corruptions introduced by Ahriman, the evil spirit. The Chaldeans retained a similar account to that of Moses, representing like it a race of giants as living before the time of the flood, on account of whose impieties this punishment was inflicted. Berosus, in whose writings this narrative was found and appealed to by Josephus, as corroborating the Jewish account, states that the remains of the ark were still to be seen in the mountains of Armenia, and that the people continued to collect the asphaltum from it for a charm. Abydenus found in the archives of the Medes and Babylonians a similar statement of the ark being in preservation at these mountains, and visited by people for the purpose of obtaining relics of it. He speaks of Noah as a king, whom he calls Seisithrus, and narrates, as many of the other traditions do, the sending out of birds from the ark, and their return with traces of mud upon their feet. Some of the Christian fathers, as Theophilus and Chrysostom, speak of the ark as existing even in their time. The Noah of the Greeks was Deucalion, and the account given of the flood, in which he and his wife Pyrrha were saved in a ship, is remarkably similar to that of the Noachian deluge. While connected with this in most of its particulars, one incident on the other hand serves to give it a close relation to the more obscure traditions preserved by very different races in a far distant part of the globe. After leaving the ship, it is stated to have been the first care of Deucalion to consult the oracle of Themis as to the means by which the earth should be repeopled. The response of the oracle was that Deucalion and Pyrrha should veil their faces, unloose their girdles, and throw behind their backs the bones of their great mother. Construing this to mean the earth, they threw behind them the stones gathered from the surface. Those thrown by Deucalion became men, and those thrown by Pyrrha became women. The Mexicans are described by Humboldt as having, with many of the rude nations of the new world, their traditions of the great deluge. They say a man and woman were saved upon a high mountain named Tamanacu, and casting behind them over their heads the fruit of the mauritia palm tree, they saw men and women spring up from the seeds of these fruits. Prescott ("Conquest of Mexico," vol. iii. p. 373) notices other traditions resembling the Scripture account of the deluge. The Peruvians date back the period of the deluge to a time long anterior to the existence of their incas. The original inhabitants of the island of Cuba are said to have been found possessed of the story of the deluge with the incidents of that of Noah, the ark, the animals introduced into it, the sending out a bird (in this instance a crow) to look for dry land, and its return to the ark. Our native Indians possessed traditions of a great chief being preserved upon a raft with pairs of all the animals, and finally reaching the new earth prepared for him by the Great Spirit. The inhabitants of the South sea islands preserve similar records; but among these and most barbarous tribes the traditions are modified by the peculiar habits of thought of the people, each giving a color reflected from familiar circumstances and modes of life, and each placing the scene of the great event in their own country.—These numerous traditions are variously regarded by different writers. To some they are the strongest testimony corroborating their understanding of the Scripture statement—that at some time in the early history of the race the whole human family were nearly exterminated by a terrible and universal flood. Others regard them as proving too much; for on the supposition of the various tribes having continued to occupy the territories they make the scene of the deluge from the period of its occurrence, each must have had its own ark and its own Noah; while, they say, modern researches into the characteristics and history of the species are opposed to the probability of the different races having sprung and been distributed from one common centre within the time passed since this catastrophe, as assigned by their traditions. Many, therefore, consider these histories as referring to local floods, to which all countries are more or less subject, and the accounts of which have been often unwittingly modified by those who received them, generally through languages imperfectly understood, and with feelings predisposed to find resemblances to the story which formed a part of their faith. What really was the extent of territory covered by the waters has long been a question of great interest to scholars and theologians. An account of their various theories and reasonings would here be out of place. Though the direct evidence of the deluge, which geology might naturally be expected to unfold, has been controverted repeatedly, the pursuit of the science has nevertheless brought together multitudes of instances of partial catastrophes of this nature, which have occurred at various times in different parts of the world. The possibility of elevated lakes, by the sinking of their barriers, flooding large territories, was long since shown by Sir Charles Lyell; and he also, by reference to the sinking of extensive areas, such as is now known to occur, showed in how simple a manner the vast low district bordering the Euxine and the Caspian might be flooded. The late Hugh Miller takes up and develops this view in the last of his works, the "Testimony of the Rocks;" and as this presents the opinions now entertained by many minds of the highest order in both science and religion, it may well be

presented in these pages as the most plausible exposition of this subject: "There is a remarkable portion of the globe, chiefly in the Asiatic continent, though it extends into Europe, and which is nearly equal to all Europe in area, whose rivers (some of them, such as the Volga, the Ural, the Sihon, the Koor, and the Amoo, of great size) do not fall into the ocean, or into any of the many seas which communicate with it. They are, on the contrary, all turned inward, if I may so express myself, losing themselves in the eastern part of the tract, in the lakes of a rainless district, in which they supply but the waste of evaporation, and falling in the western parts into seas such as the Caspian and the Aral. In this region there are extensive districts still under the level of the ocean. The shore line of the Caspian, for instance, is rather more than 83 feet beneath that of the Black sea; and some of the great flat steppes which spread out around it, such as what is known as the steppe of Astrakhan, have a mean level of about 30 feet beneath that of the Baltic. Were there a trench-like strip of country that communicated between the Caspian and the gulf of Finland to be depressed beneath the level of the latter sea, it would so open up the fountains of the great deep as to lay under water an extensive and populous region, containing the cities of Astrakhan and Astrabad, and many other towns and villages. Nor is it unworthy of remark, surely, that one of the depressed steppes of this peculiar region is known as the 'Low Steppe of the Caucasus,' and forms no inconsiderable portion of the great recognized centre of the human family. The Mount Ararat on which, according to many of our commentators, the ark rested, rises immediately on the western edge of this great hollow; the Mount Ararat selected as the scene of that event by Sir Walter Raleigh, certainly not without some show of reason, lies far within it. Vast plains, white with salt, and charged with sea shells, show that the Caspian sea was at no distant period greatly more extensive than it is now. In an outer region, which includes the vast desert of Khiva, shells also abound; but they seem to belong, as a group, rather to some of the later tertiary eras than to the recent period. It is quite possible, however, that, as on parts of the western shores of our own country, where recent marine deposits lie over marine deposits of the pleistocene age, while a terrestrial deposit, representative of an intervening paroxysm of upheaval, lies between; it is possible, I say, that in this great depressed area, the region covered of old by a tertiary sea, which we know united the sea of Aral with the Caspian, and rolled over many a wide steppe and vast plain, may have been again covered for a brief period (after ages of upheaval) by the breaking in of the great deep during that season of judgment when, with the exception of one family, the whole human race was destroyed. It seems confirmatory of this view, that during even the historic period at least one of the neighboring inland seas, though it belongs to a different system from that of the Caspian and the Aral, covered a vastly greater area than it does now—a consequence apparently of a more considerable depression in the Caucasian region than at present exists. Herodotus, as quoted by Cuvier in his 'Theory of the Earth,' represents the sea of Azov as equal in extent to the Euxine. With the known facts then regarding the depressed Asiatic region before us, let us see whether we cannot originate a theory of the deluge free from at least the palpable monstrosities of the older ones. Let us suppose that the human family, still amounting to several millions, though greatly reduced by exterminating wars and exhausting vices, were congregated in that tract of country, which, extending eastward from the modern Ararat to far beyond the sea of Aral, includes the original Caucasian centre of the race; let us suppose that, the hour of judgment having at length arrived, the land began gradually to sink, as the tract in the Run of Cutch sank in the year 1819, or as the tract in the southern part of North America, known as the 'sunk country,' sank in the year 1821; further, let us suppose that the depression took place slowly and equally for 40 days together, at the rate of about 400 feet per day—a rate not twice greater than that at which the tide rises in the straits of Magellan, and which would have rendered itself apparent as but a persistent inward flowing of the sea; let us yet further suppose that, from mayhap some volcanic outburst, coincident with the depression, and an effect of the same deep-seated cause, the atmosphere was so affected, that heavy drenching rains continued to descend during the whole time, and that though they could contribute but little to the actual volume of the flood—at most only some 5 or 6 inches per day—they at least seemed to constitute one of its main causes, and added greatly to its terrors by swelling the rivers, and rushing downward in torrents from the hills. The depression which, by extending to the Euxine sea and the Persian gulf on the one hand, and to the gulf of Finland on the other, would open up by 3 separate channels the fountains of the great deep, and which included, let us suppose, an area of about 2,000 miles each way, would, at the end of the 40th day, be sunk in its centre to the depth of 16,000 feet—a depth sufficiently profound to bury the loftiest mountains of the district; and yet, having a gradient of declination of but 16 feet per mile, the contour of its hills and plains would remain apparently what they had been before; the doomed inhabitants would see but the water rising along the mountain sides, and one refuge after another swept away, till the last witness of the scene would have perished, and the last hilltop would have disappeared; and when after 150 days had come and gone the depressed hollow would have begun slowly to rise, and when after the 5th month had passed the ark would have grounded on the summit of Mount Ararat, all that could have been seen

from the upper window of the vessel would be simply a boundless sea, roughened by tides, now flowing outward, with a reversed course, toward the distant ocean, by the 3 great outlets which, during the period of depression, had given access to the waters. Noah would of course see that 'the fountains of the deep were stopped,' and that the waters returned from off the earth continually; but whether the deluge had been partial or universal, he could neither see nor know. His prospect in either case would have been equally that described by the poet Bowles:

> The mighty ark
> Rests upon Ararat; but naught around
> Its inmates can behold, save o'er the expanse
> Of boundless waters the sun's orient orb
> Stretching the hull's long shadow, or the moon
> In silence through the silver-curtained clouds
> Sailing, as she herself were lost and left
> In hollow loneliness."

DEMADES, an Athenian orator (died 318 B. C.), who, from being a sailor or fishmonger, raised himself to a prominent position at Athens. He belonged to the pro-Macedonian or peace party, and was the virulent opponent of Demosthenes. He fought, however, at Chæronea in defence of Grecian liberty, and was taken prisoner, but Philip restored him his freedom, and treated him with marked distinction. He used his influence with the conqueror to obtain favorable terms for his native city. After the death of Philip he became the steady supporter of Alexander's supremacy; and when after the destruction of Thebes Alexander demanded the surrender of Demosthenes, Demades, under the incentive of a bribe from the friends of the latter, interceded with the king, and mitigated his vengeance. Afterward, when Demosthenes and his friends left the city on the approach of Antipater and Craterus, he induced the people to pronounce sentence of death against them. Having been sent as ambassador to Antipater, the latter put him to death on discovering letters of his in which he urged the enemies of that general to attack him. Demades was a great wit, and excelled as an extemporaneous orator. A large fragment of an oration commonly ascribed to Demades, in which he defends his political conduct during Alexander's reign, is contained in the collective edition of the Attic orators, but its genuineness is contested. Cicero and Quintilian both assert that Demades left no orations behind him.

DEMAVEND, Mount, the highest summit of the Elbrooz mountains in Persia, between the provinces of Irak-Ajamee and Mazanderan, lat. 35° 50′ N., long. 52° E. It is an extinct volcano, conical in shape, and about 15,000 feet high. It yields large quantities of pumice stone and pure sulphur, and around its base are several hot springs.

DEMBINSKI, Henryk, a Polish general, born in the palatinate of Cracow, Jan. 16, 1791. His father, a zealous adherent of the anti-Russian party, and of the constitution of May 3, urged upon his young sons in his will the duty of defending the same principles through life; his mother, a patriotic and accomplished woman, educated them accordingly. Having studied for 2 years at the Vienna academy of engineers, Henryk left it in 1809, refusing to accept a commission from the Austrian government, and enlisted as a common soldier in the national army of the newly created duchy of Warsaw. He became a lieutenant at the opening of the campaign against Russia in 1812, was made captain by Napoleon on the battle field of Smolensk, distinguished himself in the battle of Leipsic, was subsequently attached to Gen. Wielohorski, then at Paris, and returned to his native country after the fall of the French empire. Having married, he engaged successfully in agricultural pursuits, and in 1825 was elected a member of the Polish diet, where he acted with the opposition. After the outbreak of the revolution at Warsaw (Nov. 1830), he was appointed major of a regiment formed in his native palatinate, was intrusted with the command of the mobile national guard of the same, marched with his troops to the capital in Feb. 1831, received from Skrzynecki the command of a cavalry brigade, and fought bravely at Dembe and Liw, and with still greater distinction at Kuflew, against the overwhelming army of Diebitsch. Sent to defend a bridge of the Narew, he repulsed the Russians after a bloody battle of 14 hours. He was next attached to the expedition to Lithuania, which, being undertaken too late and under Gielgud and Chlapowski, proved a failure after a few successful engagements. Gielgud was shot as a traitor by one of his followers; Chlapowski crossed the Prussian frontier and surrendered. Dembinski alone led his detachment through the marshes and forests of Lithuania, partly amid and partly behind the Russian armies, back to the capital, where he unexpectedly appeared on Aug. 5, and was received with great enthusiasm by the people, and with public thanks by the diet. Made governor of Warsaw, he was also for a few days successor in the chief command to Skrzynecki, but soon disappointed the hopes he had excited. After the fall of Warsaw in September he followed Rybinski to Prussia, went thence to France, where he published his *Mémoires sur la campagne de Lithuanie* (Strasbourg, 1832), and in 1833 to Egypt, to assist in the organization of the army of Mehemet Ali, whose offensive operations, through Ibrahim Pasha, against the Porte, which was supported by Russia, promised to offer a new theatre of war against the latter power. This hope, however, soon vanished, and Dembinski returned to France, where he lived in comparative retirement till 1848, when after the outbreak of February he went to Germany, and was present at the so-called Slavic congress of Prague. Having returned to Paris, he was persuaded by Count Teleky to accept a command in Hungary, while his old colleague Bem was already engaged in reconquering Transylvania. He succeeded in passing through Germany and over the Austrian frontier, arrived at Debreczin in

Jan. 1849, made his first appearance on the battle field in the camp of Perczel, who was then executing a successful manœuvre against the Austrians on the right bank of the Theiss (Jan. 23), and received the chief command of the main Hungarian army on Feb. 5 The machinations of Görgey, however, who was impatient of being subordinate to another, and he a foreigner, soon hindered the plans and operations of Dembinski. The Austrian general Schlick, allowed to retreat from Kaschau, baffled Dembinski's attempt to stop him at Putnok, forced his way through the mountains of Gömör and Heves, and appeared on the right flank of the Hungarian army, in the great battle of Kápolna (Feb. 26, 27), where the latter was attacked while marching to take the offensive. This unexpected event, and the want of precision in the execution of the orders on the part of Görgey's divisions, owing in part to their distribution on the vast battle field in consequence of Dembinski's distrust of that general, caused the retreat of the Hungarian army to Kövesd, where an attack of the enemy (Feb. 28) was successfully repulsed, and finally beyond the Theiss, amid difficulties caused by the marshy nature of the ground, deficiency of provisions, and attacks of the Austrians. On their arrival at Füred several of the officers openly declared their want of confidence in the abilities of the Polish general, and the government was thus compelled to deprive him of the chief command. In the spring he received the command of a corps in the north of Hungary, which, however, he soon resigned to Gen. Wysocki, being unable to agree with the ministry of war regarding the operations. On July 2, when Görgey's continued disobedience amid the advance of the Russians and Austrians from every quarter finally forced Kossuth to more decisive action, Dembinski received the virtual, and his friend Lieutenant Field Marshal Mészáros the nominal command of all the Hungarian armies. But the order for concentration was not executed; Görgey still acted independently, and reached the Theiss only after a lengthened though victorious retreat, and when the Russians had crossed it; Dembinski was defeated at Szöreg (Aug. 5), and forced to give up the lines of the Theiss and Maros. Instead of falling back upon Arad, where Görgey's army was expected to arrive, Dembinski, dreading either the treachery of that rival, or the relief of Temesvár, which was about to surrender, by the enemy, retreated toward the latter fortress, and there lost (Aug. 9) the bloody battle which sealed the fate of the revolution, in spite of the coöperation on that day of Bem, Guyon, Kmety, Perczel, Wysocki, and other leaders. The remnants of the army retreated toward Lugos, Görgey surrendered (Aug. 13), and Dembinski sought refuge with Kossuth in Turkey, whence, as a citizen of France, he was allowed to return to that country in 1850. A Polish pamphlet entitled "A Glance at the Last Events of the Polish Revolution," was published by him in Paris, in 1837; his memoirs of the Hungarian campaign are still expected.

DEMERARA, one of the 3 counties into which the colony of British Guiana in South America has been divided since 1831, derives its name from the river Demerara. It lies between lat. 0° 40′ and 8° 40′ N., and long. 57° and 61° W., is situated between the other 2 counties, Essequibo and Berbice, and occupies the centre of the seaboard for about 90 m. Pop. according to the census of 1851, 75,767, including that of Georgetown (25,508), which is the capital of the county and of the colony. (See Guiana.)

DEMETER. See Ceres.

DEMETZ, Frédéric Auguste, a French philanthropist, born May 12, 1796. He was bred to the law, and officiated for several years as one of the judges of the court of *police correctionelle* at Paris. Thus his attention was called to the great number of juvenile offenders, for whom at that time there was no house of correction, or place of confinement, except with the adult prisoners, from whom they soon learned to become adepts in crime. Fortunately, about this period M. Lucas, the inspector-general of prisons, conceived the idea of establishing a benevolent institution, with a view to aid in the reformation of some of these juvenile criminals. Of this society M. Demetz early became an active member, and was finally sent with M. Léon Faucher by the society to investigate the condition and results of the agricultural colonies which had been established in Belgium and Holland for the reformation of young offenders. M. Demetz also visited Hamburg, and at the *rauhes Haus*, near that city, then as now under the superintendence of Dr. Wichern, he found the model of a reformatory colony which he had thus far sought in vain. Having returned to France, M. Demetz, in connection with the viscount de Courteilles, established in 1839 the colony of Mettrai, near Tours, the viscount offering a portion of his own estate for the experiment. In July of that year they assembled 23 young men of good families there, and occupied themselves in training them for teachers for the young offenders who were to be brought there. In Jan. 1840, they admitted 12 young criminals, and gradually increased the number, till now they have more than 700 of this class under training. Since the death of Courteilles (1854) the superintendence of the establishment has devolved on M. Demetz. The success of this colony has led to the organization of many similar establishments in Great Britain and in continental Europe. M. Demetz has aided many of these enterprises by his presence and personal influence, particularly in England. He has published *Rapports à M. le comte de Montalivet sur les pénitenciers des États Unis*, the result of his investigations during his visit to the United States in 1836, in company with M. de Tocqueville.

DEMETRIUS, or Dmitri, the name of several Russian princes, who reigned in the 13th, 14th, and 17th centuries. The most important of them is known under the name of Dmitri

Samozvanietz, or the Pseudo Demetrius, and is generally believed to have falsely assumed the name of the younger surviving son of Ivan the Terrible, who during the reign of the elder son, the feeble Fedor, was confined by Boris Godunoff, the brother-in-law and ruler of the czar, in the town of Uglitch, and died there in 1591 a violent death, which was attributed by his mother to the treachery of Boris. The young prince was found in his blood, the knife with which he had been playing in his throat; some visitors from the court were pointed out by the lamenting mother as the murderers, to the gathering people of the place, who, fanatically revering the house of Rurik, and hating the usurper, rushed upon the strangers and massacred them. Boris took fierce revenge for this insult on the people and town of Uglitch, and ample testimony was procured to prove before his tribunal that Demetrius died accidentally. His despotic though energetic reign before and after the death of Fedor, the last of the Ruriks (1598), had prepared the minds of the Russians for a rebellion, when rumors of Demetrius having escaped the hands of the assassins by the substitution of another victim spread over the country. The pretender, whose real name and origin are still a mystery, made his first disclosures in 1603 at the court of Prince Adam Wisniowiecki in Lithuania, where he was serving in the capacity of a page. Prince Constantine Wisniowiecki, the brother of Adam, introduced him to his father-in-law, Mniszek, palatine of Sandomir. Some of the Polish nobles and their friends were gained by the persuasive skill of the pretender, others were incited by hopes of adventures or gain to support him, while Mniszek was fascinated by the prospect of seating upon the throne of Russia his beautiful and ambitious daughter, Maryna, for whom the youth declared his love. An audience of the king, Sigismund III., was easily gained, and, the interests of both the state and the Catholic church decisively pleading in favor of the cause, the nobles were allowed to set on foot an expedition to Moscow, independently of the government. The future czar was zealously assisted by the Jesuits, whose influence had now begun to be of great weight in the councils of Poland, and some historians, therefore, suspect him to have been the *élève* and tool of the order. A simultaneous revolt of the Russian Cossacks against the rule of Boris, under the lead of Grishka (Gregory) Otrepieff, a runaway monk, seconded the enterprise. The menaced prince, in order to degrade his rival, identified him with the leader of the Cossacks, a statement which afterward misled some intelligent writers. The invading army, about 5,000 strong, was reenforced in Russia by detachments of Cossacks. Some of the strongest cities, summoned in the name of the son of Ivan, voluntarily opened their gates; others were taken. Novgorod Seversk alone, defended by Basmanoff, successfully checked their march, thus effectually assisting the operations of the opposing army. Having vanquished Prince Mstislavski in Dec. 1604, the pretender was in his turn defeated by the same general in Jan. 1605, and pressed back to Pootivl; but the sudden death of Boris by apoplexy or poison soon terminated the war. Basmanoff, made commander of the army by his son and successor, Fedor, came into the camp of the enemy to implore his mercy. A deputation from Moscow offered to surrender the capital, the new czar and his family were surprised in the Kremlin and thrown into prison, and the victor entered Moscow in triumph amid the shouts of the people (June, 1605), and was crowned as Czar Demetrius. Fedor and his mother had been murdered, perhaps by his command; other members of the unhappy family also were made victims of his cruelty or policy, but a daughter of Boris was spared to become his concubine. The widow of Czar Ivan was now brought forth from the convent, in which she had so long been secluded, and her tears and embraces gave public sanction to the identity of the new czar with her son Demetrius. His reign was marked from the beginning by vigor and energy as well as ability; but his love of innovations, his undisguised predilection for the culture, institutions, and even religion of Poland, and his often expressed contempt of the customs, superstitions, and barbarous ignorance of his subjects, soon made him the object of national hatred. The arrival of his foreign spouse, with a large and pompous train of Polish nobles, warriors, and Jesuits, the arrogant and reckless behavior of some of these followers, and rumors of the czar's intended apostasy from the Russian church, finally undermined his throne. A few days after the celebration of his nuptials with Maryna, and her coronation, a band of conspirators, led by Prince Shuiski, who was indebted to Demetrius for the generous pardon of a former plot, assaulted the Kremlin. Demetrius found some faithful defenders, and evinced extreme boldness in the defence of his life, but in vain. Thousands of his men, including nearly all the Poles, were mercilessly butchered with him, by the infuriated people (May 16, 1606). Prince Shuiski was proclaimed czar under the name of Basil III., but being attacked by a new pretender, also calling himself Demetrius, and by the Poles and Swedes, was obliged to resign his throne. The origin and previous history of the new Demetrius are unknown; his abilities were of an inferior kind, but his depredations made him an object of terror, and even the capital was held by him in a kind of blockade for more than a year. Some of his men having captured Maryna, who had been released from prison to return to her country, the ambitious princess acknowledged him as her lawful husband. But the pretender was soon after murdered by a Tartar chief of his guards, and the degraded tzaritza perished miserably, according to some, in the waters of the Ural, but according to others, in prison. Even after the accession of the house of Romanoff to the throne of Moscow (1613), the convulsions caused

by pretenders, one of whom called himself a son of the first of them, were but slowly suppressed. The history of the first *samozvanietz* has been poetically adorned by Bulharin, Pushkin, and Chomiakoff, and made the subject of an unfinished drama by Schiller.—Compare P. Mérimée, *Les faux Demetrius* (Paris, 1854).

DEMETRIUS PHALEREUS, so called from being a native of the district of Phalerus, an Athenian orator and statesman, born about 345, died about 282 B. C. The son of poor parents, he studied oratory, poetry, philosophy, and statesmanship, particularly under the guidance of the philosopher Theophrastus, and began his political career in 325, as an eloquent champion of the democratic or anti-Macedonian party. This party being expelled from power, he retired into voluntary exile, but was afterward reconciled with his former opponents; and when, in 317, Cassander of Macedon became virtually master of Athens, he became governor in his behalf, being supported by a Macedonian garrison. He thus ruled Athens for 10 years with moderation and success, though not without perverting the rich revenues of the state to his personal luxury and dissipation. The degenerate Athenians rewarded his services by erecting in his honor as many statues as their year contained days, but these were scornfully broken when Demetrius Poliorcetes surprised the city, in 307, and compelled Phalereus to retire. Condemned to death in his absence, he went to Thebes, and afterward to Egypt, where he was well treated by Ptolemy, son of Lagus, but banished to the upper part of the country by his son Philadelphus, who had been made heir against his advice. He is said to have died of the bite of a snake. The foundation of the Alexandrian library has been attributed by some writers, but with little reason, to his influence with the 1st Ptolemy. In Egypt Demetrius composed numerous historical, philosophical, and literary works, of which only a few fragments are extant, the work on elocution which is known under his name being the production of an Alexandrian sophist. He is one of the last Athenian orators who deserved the name; his eloquence, however, was distinguished by grace and refinement rather than by power.

DEMETRIUS POLIORCETES (the city-besieger), one of the most conspicuous personages in the history of the long and bloody contentions which followed the death of Alexander the Great, born shortly before the accession of that conqueror to the throne of Macedon, was the son of Antigonus, who, in the first division of the Macedonian empire, received several provinces of Asia Minor for his share. In the wars of his father against Eumenes and Ptolemy, Demetrius early evinced valor and devotion to his father's cause. Commanding in Syria, he was defeated by Ptolemy in the battle of Gaza (312 B. C.), but soon restored the balance of the war by a victory over one of his generals, on which occasion he dismissed without ransom several thousands of his captives, thus repaying a similar magnanimous act of his enemy. A treaty of peace was concluded soon after, but this was of short duration, and the war was continued with various success. More decisive were his services to his father in the expedition to Greece, the most important places of which had been occupied and garrisoned by Cassander, son of Antipater of Macedon. Sailing from Ephesus (307) to Athens, Demetrius entered the harbor of the Piræus with his fleet, which was mistaken for that of Egypt, without meeting with any resistance. Demetrius Phalereus, who had ruled Athens for 10 years, in allegiance to Macedon, was compelled to retire to Thebes; Munychia and Megara, which were defended by garrisons in the interest of Cassander, were unable to withstand the skill and engines of the besieger, and he finally made his triumphant entry into Athens. Having announced the restoration of the ancient democratic institutions, and promised distributions of corn and ship timber, he was received with the most abject flatteries as god and deliverer (*σωτηρ*) by the degenerate people, who now broke the 360 statues recently erected in honor of Demetrius Phalereus. Summoned to the assistance of his father in his war against Ptolemy, he crossed over to Cyprus, defeated the Egyptian fleet, and made himself master of that island, having taken Salamis, its chief city; after which both his father and himself assumed the title of king, and their example was followed by the rival potentates of Egypt, Thrace, and Syria—Ptolemy, Lysimachus, and Seleucus. Demetrius next undertook an invasion of Egypt by sea and land, which failed, his forces being repulsed with great loss. He now turned toward Rhodes, which he besieged for more than a year; but the Rhodians, supplied and reënforced by the allied enemies of his father, withstood bravely, and the siege was terminated by a treaty. Poliorcetes then sailed to Greece, which was again threatened with the sway of Cassander. He compelled the Bœotians to relinquish their alliance with Macedon, expelled Cassander from Attica, and made himself master of Corinth, Argos, Sicyon, and most of the towns of Arcadia. In Athens the deified deliverer was received with the wonted honors, and resided as the guest of Minerva in the Parthenon, which he polluted by shameless debauchery. His pleasures and the equally degrading manifestations in his honor were again interrupted by the call of his father, which he was always ready to obey. He hastened to Asia, and fought in the great battle of Ipsus, in Phrygia. The rival forces were nearly equal; but Demetrius, with imprudent valor, pushed too far the victorious advance of his wing; the centre, commanded by his father, was broken, and the old man was slain while yet expecting relief from his son. His dominions were broken up, the greater part falling into the hands of Seleucus. Demetrius, retiring with the remnant of his army, embarked at Ephesus for Athens, but met on his voyage with envoys from that city, who announced to him that he would

not be admitted. This defection was followed by the loss of his other possessions in Greece, his garrisons being expelled from every town. He succeeded, however, in restoring his fortunes by an alliance with Seleucus, to whom he gave his daughter Stratonice in marriage. The treaty of alliance stipulated that Demetrius should retain possession of Cilicia, Cyprus, and a part of the coast of Syria. He now armed for the reconquest of Greece, besieged and after a long resistance took Athens (295), and made a successful expedition into the Peloponnesus, when his attention was turned to Macedon. Cassander and his eldest son Philip had died; the two remaining sons, Antipater and Alexander, were engaged in a bloody struggle for the throne, and the latter invoked the aid both of Demetrius and Pyrrhus of Epirus. Pyrrhus appeared first and vanquished Antipater; Demetrius came after him, and deprived Alexander, who is said to have attempted his assassination, both of his throne and life (294). While he was thus successful in Europe, he lost his possessions in Asia, which were taken by Ptolemy and Seleucus. The following 4 years were occupied by two sieges of Thebes, an invasion of Thrace, and a war with Pyrrhus and the Ætolians, after the termination of which he was preparing for a new campaign in Asia, when he was attacked (287) by a triple invasion from Thrace, Epirus, and Egypt. While marching against the Epirotes he was deserted by his Macedonian troops, who proclaimed Pyrrhus as their king. Demetrius escaped to his son Antigonus Gonatas, who had maintained possession of Greece, and succeeded in saving a part of his dominion by a treaty with Pyrrhus. Leaving his son in Greece, he crossed over to Miletus, and fought his way as far as the northern mountain range of Syria, but was finally compelled to surrender to Seleucus, who kept his father-in-law in confinement at Apamea in Syria till his death in 283. Antigonus, who had lost almost all Greece, offered in vain the remainder of his possessions and himself for the freedom of his father, who in turn ceded to him all his claims, spending his last days in effeminate amusements unworthy of his warlike career.

DEMETRIUS (I.) SOTER (the deliverer), king of Syria, born about 187, died 150 B. C. He was the son of Seleucus Philopator, and grandson of Antiochus the Great. Sent as hostage to Rome by his father, he remained there during the whole reign of Antiochus Epiphanes, after whose death, in 164, he besought the senate to release him and acknowledge him as king of Syria. This being refused, he followed the advice of his friend, the historian Polybius, and escaped secretly from Rome. He landed at Tripolis, in Phœnicia, and was hailed as king by the Syrians; the young Antiochus V. and his tutor Lysias were put to death (162); and rich presents and ready subservience procured the acknowledgment of the new reign by the Romans. Delivering Babylon from the tyranny of a despotic governor, he received his surname of Soter, from the gratitude of that city. In his war against the revolted Jews his lieutenant Nicanor was routed by Judas Maccabæus, who also concluded a treaty of alliance with the Romans against Demetrius. His interference in the affairs of Cappadocia still more alienated from him the senate of the republic, and his oppressive rule and debauchery disgusted his own people. Instigated by the deposed governor of Babylon, one Balas rose against him, claiming to be Alexander, son of Antiochus Epiphanes, and meeting with assistance from the Romans, Jews, and Cappadocians, finally vanquished him in a battle. Demetrius was slain in his flight, after having performed prodigies of valor. Both Demetrius Nicator and Antiochus Sidetes, his sons, reigned successively after him.

DEMIDOFF, a noble and wealthy Russian family, the most distinguished members of which are the following: I. Nikita, with whom the name and nobility of the house originated, born after the middle of the 17th century, the son of a serf in the government of Toola, became a blacksmith and a manufacturer of arms, and having acquired great skill in the working of metals, established for the government the first iron foundery in Siberia at Neviansk, near Ekaterinburg (1699). This served as a model of many other flourishing establishments in the Ural mountains, and was presented to him with its dependencies by Peter the Great, who also ennobled him. II. Akinfi, son of the preceding, discovered important mines of gold, silver, and copper in different regions of Siberia, which he and his son Nikita were allowed by the government to work for their own profit by German miners. He founded the extensive iron founderies of Lower Tagielsk, was made councillor of state, and died about 1740. III. Paul, nephew of the preceding, born at Revel in 1738, died in 1826. He travelled through several countries, studied metallurgy at Freiberg in Saxony, and natural science under Linnæus at Upsal, founded at Moscow a public cabinet of natural history, a botanical garden, and a professorship of natural science, and a flourishing lyceum at Yaroslav. IV. Nicolai, nephew of the preceding, born in 1774, served in two campaigns against the Turks, travelled through Germany, Italy, France, and England, equipped at his own expense and commanded a regiment during the invasion of Napoleon, was made colonel, count, and privy councillor, and died in 1828. He enlarged the wealth of his family by mining enterprises, and added to the collections of the Moscow university a new cabinet of natural history. He is also remarkable as an author on political economy in French. V. Anatol, son of the preceding, born in Florence in 1812, was educated in France, travelled through southern Russia and adjoining countries, was made prince of San Donato by the grand duke of Tuscany, and married the princess Mathilde de Montfort, daughter of Jerome Bonaparte and Catharine of Würtemberg. But having obliged himself

to bring up his children, if any should be born, in the Roman Catholic religion, contrary to the rule of his own country and his own religion, he lost for some time the favor of the emperor Nicholas, was summoned home to answer for this offence, but was soon allowed to continue his residence in foreign countries, and lived alternately in France and Italy. His marriage, however, had no issue, and was soon dissolved. On the outbreak of the Russian war against Turkey in 1853, he was attached to the Russian legation at Vienna, and made councillor of state. On various occasions he has evinced a liberality not inadequate to his immense possessions, by donations and foundations for public charity and the promotion of science. He wrote in part the *Voyage dans la Russie méridionale et la Crimée, par la Hongrie, la Valachie, et la Moldavie* (4 vols. Paris, 1839–'41), in which he was assisted by several French scholars and artists who accompanied him.

DEMIURGE, a Greek word, meaning literally a handicraftsman, but which was applied by the Platonists to an exalted agent or *Æon* employed by the Deity in the creation of the universe. The Platonizing Christians regarded the second person in the Trinity, the Divine Word, as one of an infinite series of creators or demiurgi. The adjective demiurgic is used in sacred geology to designate the 6 days in which the world was created. (See GNOSTICS.)

DEMMIN, the capital of a circle of the same name in the Prussian district of Stettin; pop. of the circle 48,400, and of the town 7,759. The latter is situated on the frontiers of Mecklenburg-Schwerin, 70 m. from Stettin, in a valley surrounded by hills, on the bank of the river Peene. It consists of the town proper and 3 suburbs, and has manufactories of woollens, linens, hats, and hosiery, and an active trade in tobacco, corn, and timber. The town proper is surrounded by a wall with 3 gates, and was a place of great importance in the time of Charlemagne. It has sustained numerous sieges, suffered severely during the 30 years' war, and was in 1807 the scene of several engagements between the French and Russians.

DEMOCEDES, a Greek physician, born at Crotona, in Magna Græcia, about 550 B. C. He was supposed to have had the benefit of general training under Pythagoras. The severity of his father, Calliphon, caused him to leave his home and settle at Ægina, where he was very successful. Thence he went on invitation to Athens, and soon afterward he entered the service of Polycrates, tyrant of Samos. Accompanying his patron on his visit to Orœtes, satrap of Sardis, he shared that patron's misfortune, and became a slave. When Orœtes was put to death by order of the great king, Democedes was seized as one of his slaves, and sent to Susa. Darius Hystaspes, then monarch of Persia, having sprained his foot badly when leaping from his horse, suffered severely, and could obtain no relief until some one recollected the Greek surgeon who had been seized at Sardis, and who, in chains and rags, was brought to the royal chamber. At first Democedes denied his surgical skill, but threats of torture were sufficient to make him confess the truth. He cured the king, and was royally rewarded, both by Darius and by the women of the harem. Democedes wished to return home, but the king would not grant him permission; and he had before him, of all things the most unpleasant to a Greek, the prospect of spending his days in a foreign land, when circumstances wrought his liberation. His professional services were sought by Atossa, the principal wife of Darius. She was afflicted with a tumor on the breast, and called in the Greek, who promised to cure her if she would swear to do for him any thing he might ask. Having promised, and the cure effected, she readily sought to procure him permission to return to Greece, which was what he asked for his reward. Knowing that direct means would be useless, he taught her to deceive the king, though it is not probable she was aware of his purpose. When Darius told her that he was about to undertake an expedition against the Scythians, she asked him to change his purpose, and to attempt the conquest of Greece, alleging that she desired some Greek maidens for slaves, and telling him that Democedes was the best person to give information about his country. The king was induced to send the surgeon to Greece, accompanied by 15 Persians, on a secret mission. The Greek promised to return, and to delude the king refused to take any of his own property, saying he should like to find things as they were on coming back to Susa. Laden with rich presents, he went to Sidon, where he and his comrades embarked, and a survey of Greece was made (518 B. C.). Passing to Italy, Democedes persuaded the ruler of Tarentum to seize the Persians as spies, while he continued his journey to Crotona. The Persians were soon released, and proceeding to Crotona, seized Democedes in the market place; but he was rescued by his fellow citizens, who also robbed the Persians of their store ship. On parting with his Persian companions, he bade them tell Darius he was about to marry the daughter of Milo the wrestler, whose fame had reached to Susa. The Persians were shipwrecked on their way home and made slaves, but were recaptured and restored to their home by a Tarentine named Gillus. Nothing more is known of the career of Democedes; he is said to have written a work on medicine, and his professional reputation was almost equal to that of Hippocrates.

DEMOCRACY (Gr. δημος, people, and κρατεω, to rule), the government of the people by themselves. By the Greeks democracy was understood to mean the government of a state by a large body of citizens, in opposition to aristocracy, the government by a few rich or high-born families. In most of the Greek republics there was a perpetual struggle for political power between two classes or factions of the citizens, whose general broad distinction was into poor and rich, or into the many and the few, which, as Aristotle

remarks, are convertible terms, for it is always the rich who are the few and the not rich who are the many. The contests of these factions led to frequent revolutions, and a state was said to be democratic or aristocratic as the one or the other prevailed. But the Greek republics were never at any time democracies in the modern sense of the term. They were all aristocracies, some of them with a broad, others with a narrow basis of citizenship. Of government by the people, meaning by the people all the adult males of a nation, ancient history gives us no example. The fundamental basis of democracy is the recognition of the rights of man as man. Its central principle is the equality of all men before the law, without regard to birth, property, or social rank; from which principle is deduced the right of all men to an equal voice or vote in deciding upon public affairs, or in selecting agents and representatives to perform the functions of legislation and to execute the laws. The principles of democracy are forcibly and clearly stated in the American declaration of independence, in the words of Thomas Jefferson, who has been called "the apostle of democracy": "We hold these truths to be self-evident: that all men are created equal; that they are endowed by their Creator with certain inalienable rights; that among these are life, liberty, and the pursuit of happiness. That, to secure these rights, governments are instituted among men, deriving their just powers from the consent of the governed." These principles are still more fully developed in the constitutions of the states of the Union. The constitution of New Hampshire (1792) says: "All men are born equally free and independent; therefore all government of right originates from the people. . . . All power residing originally in and being derived from the people, all the magistrates and officers of government are their substitutes and agents, and at all times accountable to them." The bill of rights prefixed to the constitution of Virginia in 1776, adopted by the convention of 1829–'30, and re-adopted by the convention of 1850–'51, says: "All men are by nature equally free and independent, and have certain inherent rights, of which, when they enter into a state of society, they cannot by any compact deprive or divest their posterity; namely, the enjoyment of life and liberty, with the means of acquiring and possessing property, and pursuing and obtaining happiness and safety. All power is vested in, and consequently derived from, the people; magistrates are their trustees and servants, and at all times amenable to them." The constitution of Florida (1838) says, "that all elections shall be free and equal, and that no property qualification for eligibility to office, or for the right of suffrage, shall ever be required in this state." The Greek republics were founded on principles very different from these. Political power among them was never given to the mass of the people. It was carefully kept in the hands of a privileged class, even when the most liberal parties were in the ascendant. In the Athenian republic, the most democratic of the Greek states, when the population and the suffrage were most extended, in 317 B. C., there were but 21,000 persons entitled to vote out of a total number of more than 500,000. In 444 B. C. there were 19,000, but upon a revision of the lists being made at the suggestion of Pericles, nearly 5,000 names were struck off because those who bore them did not belong to the privileged class. Thus at the most splendid period of Athenian history, only 14,000 persons, or about 1 in 40 of the population, had a right to vote. In aristocratic England about 1 in 20 are voters, while with truly democratic institutions in any country the proportion of voters to the population will be as 1 to 5 or 6. Sparta was still more undemocratic than Athens. The number of voters in Laconia at the time of the Persian wars, according to Herodotus, was only 8,000, while the number of free citizens who were rigidly excluded from political power is computed to have been 16,000, exclusive of women, children, and slaves. In 369 B. C. the number of Spartan voters had fallen to 2,000; fifty years later there were scarcely 1,000, and in 244 B. C. they had diminished to 700. The Roman citizens, 93 B. C., numbered 463,000, which was probably about $\frac{1}{50}$ of the population of Italy at that period. The Italian republics of the middle ages were also far from being democratic in their institutions. In fact, real democracy was first put in practice in government by the colonies of New England. In Connecticut, in 1639, the elective franchise was given to all men who had taken an oath of allegiance to the commonwealth; the magistrates and legislature were chosen annually by ballot; and the representation was apportioned to the population. To this day the most perfect democracies in the world are the towns of New England, where the whole adult male population assemble together and decide by their votes their own public affairs.—Much confusion of ideas on the subject of democracy has been caused by not discriminating between political and social democracy, between the democracy of laws and the democracy of sentiment and manners. The principle of the legal and political equality of men is not inconsistent with the utmost variety of natural and social distinctions. It only forbids the creation by law of artificial distinctions. The example of the American people shows that democratic political institutions are compatible with very great inequalities in cultivation, manners, style of living, social consideration, and the distribution of property.

DEMOCRITUS, the father of the atomistic philosophy, born in Abdera, Thrace, about 460 B. C., died in 361. He inherited a large fortune, travelled extensively in Asia, made himself acquainted with the various schools of philosophy of his day, and was promoted to high offices on his return to his native country. He was called the "laughing philosopher," in contrast to the "weeping philosopher" Heraclitus, because he taught that a philosopher must never

trouble himself about the follies of man, but regard them with the most serene equanimity. He wrote many works on physical, moral, mathematical, musical, and technical subjects. The most complete collection of the small remnants of his writings extant is that of Mullach (Berlin, 1843). "Every thing," he says, "is composed of atoms or infinitely small elements, each with a definite quality, form, and movement, whose inevitable union and separation shape all different things and forms, laws and effects, and dissolve them again for new combinations. The gods themselves and the human mind originate from such atoms. There are no casualties; every thing is necessary and determined by the nature of the atoms, which have certain mutual affinities, attractions, and repulsions."

DEMOIVRE, Abraham, a French mathematician, born at Vitry, in Champagne, May 26, 1667, died in London, Nov. 27, 1754. Upon the revocation of the edict of Nantes, he took refuge in England, and devoted himself to teaching mathematics. He soon became connected with Halley and Newton, was admitted into the royal society of London in 1697, and was one of the committee appointed to decide on the rival claims of Leibnitz and Newton to the invention of the method of fluxions. He survived most of his early associates, and his subsistence latterly depended upon his solutions of problems relative to games of chance, which he was accustomed to give in a coffee house. Beside memoirs in the "Philosophical Transactions," he published the "Doctrine of Chances" (1718), the "Annuities on Lives" (1724), and *Miscellanea Analytica, de Seriebus et Quadraturis* (1730).

DEMON (Gr. δαιμων), a name given by the ancients to a spirit, or immaterial being, supposed to hold a middle place between men and the celestial deities. Demonology plays a prominent part in the oldest religions of the East, and it was an element in the original worship of the dark-colored primitive inhabitants prior to the Aryan migration—of the whole Finnish-Turkish-Mongolian stock, including the occupants of China, Thibet, and Further India. More ancient in India than the Vedas, it has maintained itself there either secretly or by public sanction alike in Brahminism, Buddhism, and Islamism. Its fullest and most systematic development is found in Buddhism, which reckons 6 classes of beings in the universe, 2 only of which, those of men and gods, are accounted good; the other 4—the Asuras, irrational animals, Pretas or goblins, and the denizens of hell—being esteemed evil. The Asuras are the most powerful of the wicked spirits, and, like the Greek Titans and the Scandinavian Jotuns, are in constant warfare with the gods (*Devas*), the contest being already begun in the age of the Vedas. They dwell beneath the 3-pronged root of the world-mountain, occupying the nadir, while their great enemy Indra, the highest Buddhist god, sits upon the pinnacle of the mountain in the zenith. The Meru, which stands between the earth and the heavens, around which the heavenly bodies revolve, causing day and night according as they are on one side or the other of it, is the battle field of the Asuras and the Devas. The 3 lower divisions of the Meru are held by various races of demons, the 4th being the lowest heaven, and occupied by the 4 Maharadshas, who are appointed to be kings of the demons. Around the Asuras cluster numerous associated groups, as the Rakshasas, probably of Aryan origin, appearing sometimes as gigantic opponents of the gods, sometimes as terrible ogres with bloody tongues and long tusks, eager to devour human flesh and blood, and lurking in fields and forests; the Jakshas, malignant and mischievous, yet little to be feared, honored by the original Asiatics as aërial spirits, and exalted by the Brahmins to be servants of Kuvera; the Nagas, snakes with human countenances; the Mahoragas, great dragons; the Khumbandas, shapeless dwarfs, of uncertain origin, but unknown to the Brahminic demonology; the Kinnaras, horned, and having a horse's head, the musicians of Kuvera, and dangerous to men; the Gandharbas, the musicians of Indra; the Garudas, kings of birds; and the Picatshas, or vampires. According to their nature and office, the different species of demons dwell in the air, the water, the earth, in holes and clefts, in the lower portions of the Meru, with the gods whose servants they are, or on the golden mountains which enclose the inland seas in the Buddhistic system of worlds.—Among the Persians the Indian terminology is transposed, the great Asura representing the good creating principle, and the devs being the evil spirits; thus indicating that religious antagonism at some time existed between the eastern and western Aryans. As completed by Zoroaster, the Persian system made the principle and personifications of evil nearly an equal balance and eternal parallel with the good principle and its personifications. Ormuzd created 6 resplendent angels of love and holiness, called Amshaspands, himself being the 7th and highest; Ahriman then created the 6 archdevs, to oppose the Amshaspands, to paralyze their efforts for good, and substitute evil. Ormuzd created 28 Izeds, or beneficent spirits, who presided over the heavenly bodies, and showered good gifts upon men; but Ahriman made the 28 devs to counteract their influence, and to cause all manner of turmoil and distress. The most powerful and pernicious of the devs was the two-forked serpent Ashmogh. The next series of Ormuzd's creations was an infinite number of Fervers, spirits representing the archetypes of all things, and which became the guardian angels of men, animals, and plants. Ahriman made an equal number of corresponding evil spirits, so that every man and thing has its attendant bad as well as good genius. To arrest the progress of evil, Ormuzd made an egg filled with spirits of light, but Ahriman made an egg which contained an equal force of spirits of darkness, and then broke both together, so that good and

evil were only the more confounded. Ormuzd created the material world, but could not exclude Ahriman and his ministers from its deep opaque elements. Ormuzd created a bull, the symbol of life, which Ahriman slew. From its blood grew the original plants and animals, to harass and destroy which Ahriman made wolves, tigers, serpents, and venomous insects. From its bleached elementary particles grew the ribas tree, into the stems of which Ormuzd infused the breath of life, and they became the first man and the first woman; but every human being is tempted through his whole career by Ahriman and his devs, which slip into the body and produce all diseases, and into the mind and produce all malice. While human life thus hangs wavering between two antagonistic agencies, each of which would be infinite but for the other, it is declared that ultimately Ahriman shall be overpowered, driven through torrents of melted lead, purified, and forgiven, and Ormuzd shall reign supreme.—In the ancient Egyptian religion, Seth (or Typhon) was the manifestation of the abstract idea of evil, as Osiris was of good. It is abundantly illustrated in the early sculptures that they were regarded as brothers, as parts of the same divine system, and both worshipped as gods. The emblems were designed to show that good and evil affected the world equally, and existed together as a necessary condition of human existence; thus the Indian systems had admitted both the creator and destroyer as characters of the divine being. So nearly equal in esteem were Seth and Osiris, that their names are sometimes interchanged as if synonymous in the titles of the older kings; and Seth is represented in attendance with other gods pouring from a vase the symbols of life and power over the newly crowned king. At a later period, probably through the influence of foreigners from Asia, evil was resolved into sin; Seth was confounded with the snake-giant Apophis, the enemy of gods and men; and the brother of Osiris no longer received divine honors. His name and square-eared figure were effaced; he ceased to be esteemed a necessary antagonistic companion to Osiris, and was regarded as acting in opposition from his own free will, as Ahriman opposed Ormuzd, or as the Manichæan Satan opposed God; and he was expelled from the Egyptian pantheon, perhaps in the time of the 22d dynasty. The representation of the great serpent Apophis, the symbol of sin, as pierced by the spear of Atmoo (or Horus), may have been the antetype of the python slain by Apollo.—Demons first appear distinctly in the religious world of the Greeks, in the "Works and Days" of Hesiod. In Homer they are not distinguished from the gods, and the name is applied to the Olympian divinities. The Homeric personages most nearly corresponding to the oriental and mediæval demons are the Titans, the representatives of force acting against the divine government, and especially Ate, the representative of guile and mischief. Ate is the power that tempts and misleads men to their own cost and ruin, as they afterward find out. She may even tempt the Deity also, for she beguiles Jupiter himself when Hercules is about to be born (Iliad, xix. 95). Mr. Gladstone thinks her traditionally connected with the Hebrew conception of the Evil One, and says that her nature and function are best expressed by the English word "temptress." Hesiod makes the demons generically different from the gods, but yet essentially good. They were, according to him, the long departed golden race of men, who after death had become guardian terrestrial demons, watching unseen over the conduct of mankind, with the regal privilege, granted by Zeus, of dispensing wealth and taking account of good and bad deeds. They formed the intermediate agents and police between the gods and men. The demon of Socrates is an eminent example of faith in a ministering and benevolent spirit, specially devoted to the welfare of a single person, and inspiring him with wisdom; and bears resemblance to the guardian angels in Christian conception, and to the familiar spirits of mediæval magicians. The Hesiodic creed received an important modification from the later philosophers. Empedocles first introduced the distinction of beneficent and maleficent demons, with every grade of each; and was followed by Xenocrates, Plato, Chrysippus, and Plutarch. Perhaps the reckless and half wicked silver race which Hesiod represents as buried in the under world, where, though not recognized as demons, they nevertheless had a name, dignity, and substantive existence, may have been the germ of the conception of perverse and malignant demons. This modification of the doctrine, as Plutarch says, relieved the philosopher from great difficulties in the consideration of divine providence, since many phenomena which could hardly be attributed to the gods, could thus be explained by referring them to the agency of demons. The old myths had erred in assigning to the great divinities proceedings inconsistent with their dignity; and both the truth of the legends and the exaltation of the divine character were saved by supposing that the terrific combats, Titanic convulsions, the abductions, flights, concealments, and other discreditable mythological actions, had been the work of bad demons, who were far beneath and unworthy the notice of the tranquil and immortal gods. The objectionable religious mysteries and ceremonies, too, which custom retained, were necessary as the only means of appeasing, not the gods, but the malignant demons. This distinction served an important purpose in the first controversies between paganism and Christianity, the Christian writers, as Clement and Tatian, finding ample warrant in the earlier pagan authors for treating all the gods as demons, and in the later for denouncing the demons generally as evil beings. The insensible change which had taken place in the meaning of the word was thus overlooked, and it could be answered by the pagan authors

that the audience of Empedocles would repudiate one branch of the Christian statement, and that of Hesiod the other. How many of the minor Greek divinities were latterly included in popular conception or even by the philosophers among demons is indeterminate, but the early Christians traced the whole system of paganism to the agency of Satan, making all the characters of the mythology fallen angels. The pagan demons were long lived, but not immortal; Plutarch records, "Great Pan is dead;" and it is a very ancient belief that the oracles became dumb at our Saviour's birth.—In the angelology of the Jews the distinction between upright and fallen spirits appears clearly in many passages of the Old Testament, though at a later period it was corrupted by popular superstitions. With the mingling of Jewish and Hellenic ideas in the first Christian centuries, and with the speculations especially of the Alexandrian philosophers, began the manifold developments in the doctrine of demons by the cabalists and other students of the black art, which were increased by the introduction of foreign elements from the Scandinavian mythology, from the Saracens of Spain, and from the Orient through the returning crusaders, and formed the complicated and fantastic systems that in the middle ages were important elements alike in popular belief, poetry, and magic. From the Saracens were derived the djinns of Arabian and Persian romance, and from the Northmen came a knowledge of Loki, the calumniator of the gods, the grand contriver of deceit and fraud, who is beautiful in figure, but whose mind is evil, and who is unsurpassed in the arts of perfidy; in vengeance for his stratagems against gods and men he has, according to the Edda, been seized and confined in a cavern formed of 3 keen-edged stones, where he rages with a violence which causes all the earthquakes, and where he shall remain captive till the end of the ages, when he shall be slain by the doorkeeper of the gods. The Talmudists say that Adam had a wife called Lilis, before he married Eve, and that of her he begat nothing but devils. This Lilis or Lilith was a famous mediæval witch, and is introduced by Goethe in the Walpurgis night scene in "Faust." The cabalists made Adam the natural king of the world of spirits prior to his fall, and described Solomon as a most accomplished magician. They people the fire, air, earth, and water with salamanders, sylphs, gnomes, and undines, to one of which classes all evil spiritual agencies belong. This classification appears to have been borrowed from Michael Psellus, a Byzantine writer of the 11th century, who however reckoned 6 classes. Other writers made 9 kinds of demons, the same number that Dionysius made of angels. The 1st rank consists of the false gods of the gentiles, whose prince is Beelzebub; the 2d, of liars and equivocators, as the Pythian Apollo; the 3d, of inventors of mischief and vessels of anger, whose prince is Belial; the 4th, of malicious revenging devils, whose prince is Asmodeus; the 5th, of cozeners, as magicians and witches, whose prince is Satan; the 6th, of those aërial devils spoken of in the Apocalypse who corrupt the air and cause plagues, thunders, and fires, and whose prince is Meresin; the 7th is a destroyer, causing wars, tumults, combustions, uproars, who is mentioned in the Apocalypse, and called Abaddon; the 8th is that accusing, calumniating devil, called Diabolus, that drives men to despair; the 9th embraces tempters of several sorts, whose prince is Mammon. Gregorius Tolosanus makes 7 kinds of ethereal spirits, according to the number of the 7 planets, and esteems the good angels to be those which are above and the demons those which are below the moon. Marsilius Ficinus made devils the 6th in his 9 classes of intelligent beings. Wierus, a celebrated demonographer of the 16th century, in his *Pseudomonarchia Dæmonum*, following old authorities, establishes a complete infernal court, with its princes, nobles, officers, and dignities. According to him, Satan is no longer the sovereign of hell, but Beelzebub reigns in his place. The following is an outline of the court: Beelzebub, supreme chief of the infernal empire, founder of the order of the fly; Satan, leader of the opposition; Eurynomus, prince of death, and grand cross of the order of the fly; Moloch, prince of the realm of tears, grand cross of the order; Pluto, prince of fire; Leonard, grand master of the sabbats, knight of the fly; Baalberith, master of alliances; Proserpine, archdevil, sovereign princess of malignant spirits; Nergal, chief of the privy police; Baal, commander-in-chief of the infernal armies, grand cross of the order; Leviathan, lord admiral, knight of the fly; Belphegor, ambassador in France; Mammon, ambassador in England; Belial, ambassador in Turkey; Rimmon, ambassador in Russia; Thamuz, ambassador in Spain; Hutgin, ambassador in Italy; Martinet, ambassador in Switzerland; Lucifer, highest officer of justice; Alastor, executive officer in great undertakings; Nisroch, chief cook; Behemoth, chief cup-bearer; Dagon, chief pantler; Mullin, chief *valet de chambre;* Kobal, director of spectacles and amusements; Asmodeus, superintendent of gambling-houses; Nybbas, master of pageants; Antichrist, conjurer and necromancer. According to Paracelsus, the air is not so full of flies in summer as it is at all times of invisible devils. Not so much as a hair's breadth is free from them in heaven, earth, or waters, above or under the earth. Yet the sublunary spirits who alone interfere in human life have no power over the stars and heavens; they could not seduce the moon from its orbit, turn the planets from their courses, or stop rivers; they are confined beneath the moon till the day of judgment, and can work no further than God and the four elements permit them. Demons and sorcerers celebrate their nocturnal orgies in an assembly called the sabbat, which was first convened, say some cabalists, by the great Orpheus. Others, however, derive it from

the Bacchanalian revelries, but no allusion to a sabbat is found in the fathers of the church or in the decrees of councils. Sorcerers or witches bear a mark upon their bodies imprinted by the devil, which by a certain inward sensation gives notice of the hour of gathering; or in a case of urgency, a sheep is made to appear in the sky in a cloud, which is seen only by the ministers of Satan, who hasten in a moment. Ordinarily it is necessary either to sleep or to close one eye before proceeding, and sorcerers always fly to the sabbat through the air on staffs or broomsticks, or on the backs of subaltern demons, and are often transformed into goats, cats, or other animals. They usually issue from their houses through the chimney. Master Leonard, in the favorite form of a three-horned goat with a black human countenance, presides at the sabbat, and every guest does homage to him. Stolen children are brought to him, and swear through their godparents to renounce God, the Holy Virgin, and the saints, and are marked by one of his horns with a sign which they bear during their novitiate. Singing, dancing, and horrible feasting are continued till the first crowing of the cock, when the assembly suddenly disperses. Demons also retreat from the sound of bells. Angels and demons have been said to be incorporeal as compared to mankind, but corporeal as compared to God. It is remarkable that the Europeans more frequently represent demons as black, but the negroes of Africa on the contrary suppose them to be white. Bodin makes them and also the souls of departed men not only corporeal, but round in shape like the sun and moon, because that is the most perfect form, being without roughness, fractures, or prominences; yet they can assume any shape at their pleasure, appear in what likeness they will, traverse miles in an instant, transform the bodies of others into whatsoever shape, and remove them from place to place; the most powerful magicians, too, as Simon Magus, Apollonius of Tyana, Pasetes, Iamblichus, and Odo de Stellis, can force them to deceive all the senses, build castles in the air, represent armies and prodigies, command treasures, reveal secrets and future events, and perform many other such wonders. Jason Pratensis says that the devil, being a slender incomprehensible spirit, can easily wind himself into human bodies, couch in the bowels and hinder their operation, vitiate the health, and terrify the soul. Burton calls melancholy the devil's bath (*balneum diaboli*), since it is caused by the devil's mingling himself with the bodily humors.—Sorcery, or black magic, is the art of invoking the infernal powers in order to obtain from them supernatural knowledge, or the power of performing supernatural things. Cardan relates that his father, after the accustomed solemnities, conjured up, Aug. 13, 1491, 7 devils in Greek apparel, about 40 years of age, some of ruddy and some of pale complexion, who boasted their superiority to men, and affirmed that their average life was 700 or 800 years. Eric, king of Sweden, is recorded to have had an enchanted cap, by virtue of which and some magical words he could command spirits to trouble the air, make the wind blow which way he would, and raise tempests. There are witches in Sweden and Norway who make a business of selling favorable winds to sailors. The most mighty cabalistic word is *agla*, which being uttered toward the east will either drive away malignant spirits or produce marvellous revelations. In Webster's "Witchcraft" an account is given of a child, who, having heard some fearful spell muttered, caught the words, and afterward repeated them till such tempests and thunderings were produced that a whole village was burned by the lightning. Jacob Boehm declared that he could not without peril to his soul's safety disclose the original name of Lucifer, so tremendous would be its influence. In the black art there is either a compact with the devil, when he is ever at hand to do the behests of his victim, or the sorcerer invokes diabolical aid on special occasions. The devil usually appears uncalled to persons in distress, and avails himself of the temptation of the moment to conclude a pact with them, by which he extricates them, and serves them for a specified number of years, after which he shall own their soul. Thus Faust, in vain pursuit of perfect knowledge, sold himself to Mephistopheles, the second in power of the fallen archangels; and thus young men, ruined by play, were often supposed to do. The compact must be written in blood. To invoke a demon, it is necessary, for safety, that the person first enclose himself in a magic circle drawn with charcoal and blessed water, which no evil spirit can cross. The awful formulas of conjuration being then repeated, the demons first appear with frightful howlings, flashings, and tremblings, vomiting fire and fumes of brimstone all about the circle. The conjurer must not exhibit a tremor if he would keep his ascendency, but must firmly pronounce all the forms of constriction, till at length he reduces them to the human form and to gentle countenance and behavior. The conjuration must be in different words to different demons, and at different hours on the various days of the week; it is also different according to the purpose to be served; but rightly performed, it is a spell which no demon can resist. Even the most malignant of them can be compelled by a great magician to be a dutiful servant; thus Paracelsus was believed to carry a demon about with him in the hilt of his sword, which the alchemists, however, maintained to be the philosopher's stone, and no demon; and the magicians of Salamanca and Toledo imprisoned demons in rings, vials, boxes, and caskets. Solomon is reputed to have had a signet ring with the mystic word *Shemhamphorash* engraved upon it, which gave him command of the spirits, and transported him every day at noon into the firmament, where he heard the secrets of the universe. Cardan affirms that no man was ever great in any art or action that

did not have one of these demons to aid him. The conjurer should warily guard against wiles and fraud on the part of the fiends, and can only leave his circle and depart home in safety after the shrieks of the retiring demons have died away, and every trace of brimstone has disappeared. If a demon has entered into a person and "possessed" him, he can be expelled by means of exorcism. Exorcists were recognized by the council of Antioch (341) as a special ecclesiastical order, and in the Latin church are still one of the 4 minor orders of the clergy. Holy words, as the names of God, Christ, and the saints, holy water, the sign of the cross, the recitation of psalms, litanies, prayers, and adjurations, are used to expel the evil spirits who by divine permission, it is believed, not only tempt the soul of man, but sometimes also possess the human body. At the time of the reformation, the power of casting out devils was claimed, like the power of working miracles, as one of the tests of the Catholic church, and the Jesuits denied that heretical teachers had ever exhibited such power. There was also a popular belief in charms and talismans, as capable of warding off their attacks.—As exhibited in the grim superstitions and fantastic illusions of mediæval science, demonology is poetically interesting; but it has historical and tragical interest, as manifested in demoniacal possessions. To attribute certain nervous maladies and mysterious diseases to demoniacal agency has been as universal as the belief in demons. The phenomenon of preternatural and involuntary activity is often presented, followed by a cataleptic or trance-like state which overwhelms the sufferer. So wonderful is the power of sympathy, that the mania is often contagious, constraining the beholder, by a sort of fascination, to become an actor. A noted ancient example is the Corybantic and Bacchantic fury of the Greeks, manifested in violent dancing, subsequent exhaustion, and optical delusions, by which men were mistaken for wild beasts; thus Euripides (Hipp. v. 141) makes the chorus address Phedra: "O young girl, a god possesses thee; it is either Pan, or Hecate, or the venerable Corybantes, or Cybele, that agitates thee." At the commencement of our era the belief was general throughout the known world, and was recognized in the Gospels, where Christ is represented as casting out demons. Avicenna first designates, under the name of lycanthropia, the madness of men who lie hid by day, and howl about graves and deserts in the night, and will not be persuaded but that they are wolves. It was to this disease, perhaps, that Pliny referred (lib. viii. cap. 22), when he said that some men were turned into wolves in his time, and from wolves back to men again. Donat ab Altomari says that he saw two of them in his time, and that they had hollow eyes, scabbed legs and thighs, and were very dry and pale. Wierus gives an account of one that appeared in the streets of Padua in 1541, and Olaus Magnus says that they were common in Sweden. This hallucination spread through the whole of central and southern Europe. Voltaire relates that in the district of the Jura, between 1598 and 1600, more than 600 lycanthropes were put to death by a single judge. Another of the early modern epidemics, attributed to demoniacal agency, began at Aix la Chapelle. Amid the festivities of midsummer day, in 1374, a large troop of men and women from the adjacent country rushed into the city, and in the public squares and churches danced in circles with the utmost violence for hours together, apparently unconscious of the presence of spectators, till at last they sank to the ground exhausted, groaning fearfully. In this state they professed to see visions of good and evil spirits, whose names they shouted out. Incredulous spectators, who came to witness the phenomenon, were themselves seized with an irresistible impulse, and danced and became ecstatic in their turn. The epidemic spread in a few months through the Netherlands and the Rhenish provinces, and though regarded as an affair for the clergy rather than the medical faculty, yet the powers of exorcism could not always drive away the evil spirits. The authorities of the Rhenish provinces having decided to banish from the country every person who was attacked, the disease soon subsided. It reappeared at Strasbourg in 1418, and the persons who were taken with it could, according to Paracelsus, do nothing but dance until they were dead or cured. Sufferers found a resource in the legend of St. Vitus, and entitled the malady St. Vitus's dance (*chorus sancti Viti*), and they were accustomed to appeal to that saint for healing. The disease continued in Germany, and Paracelsus boasts of the number he had cured of it. About the middle of the 15th century a rumor spread through the Pays de Vaud that the environs of Bern and Lausanne were filled with sorcerers and cannibals. Children were reported to have disappeared; persons being arrested and tortured confessed that they were possessed by devils, and great numbers of them were executed. In 1549 many of the inhabitants of Artois were charged with sorcery, and confessed not only the murder and bewitching of infants and adults, but also participation in the orgies of the sabbat and association with the horrible incubi and succubi. In spite of tortures and burnings, the epidemic of bewitchment spread before the close of the century through Mentz, Treves, Saltzburg, Constance, and Ravensburg. In 1491 the nuns of Cambrai were seized with demonomania, and for 4 years ran like dogs across the country, sprang into the air like birds, climbed trees like cats, hung on the branches, imitated the cries of animals, and divined hidden things. At last the exorcists forced the devil to confess himself the cause of these things. The schools, convents, and nunneries were long favorite localities of the malady, which in these assumed its most hysterical forms. The remarkable possession of the Ursuline nuns of Loudun in 1634, which was attributed to the

black arts of the priest Grandier, presented the usual fantastic contortions and hysterical ravings, though it was perhaps chiefly a scheme of Cardinal Richelieu to wreak vengeance on a personal enemy. The delusion of witchcraft continued, thousands suffering death by fire annually throughout Europe. In the reign of Francis I. more than 100,000 witches are said to have been put to death. The first settlers in America brought with them the demoniacal traditions of Europe, and the fearful judicial condemnations of witchcraft which began at Salem in 1692, were an exhibition of the ideas and a repetition of the measures which had been in vogue for centuries. The mania, first detected in the strange caprices of a little girl, spread through the community, and Cotton Mather regarded "the assault of the evil angels upon the country as a particular defiance unto himself." Since then occasional religious excitements in this country and Europe have presented violent phenomena which associate them with the demonomanias of the middle ages. —Among the best treatises on the subject are: Horst, *Dämonomagie* (Frankfort, 1817); Ukert, *Ueber Dämonen, Heroen, und Genien* (Leipsic, 1805); Bodin, *Démonomanie* (Paris, 1587); Colin de Plancy, *Dictionnaire infernal* (3d ed., Paris, 1844); Sir Walter Scott, "Letters on Demonology and Witchcraft" (1830); and Henry Christmas, the "Phantom World" (London, 1850).

DE MORGAN, Augustus, an English mathematician, born on the island of Madura, in the East Indies, in 1806. His father was an officer in the British army, and he was educated at Trinity college, Cambridge, where he took the degree of bachelor of arts in 1827. He had begun his studies for the bar when, in 1828, on the foundation of the university of London (known since 1837 as University college, London), he was appointed to the professorship of mathematics in that institution. He resigned this position in 1831, but returned to it on the death of his successor, in 1836, and has since retained it. He has written voluminously on the principles and history of mathematics, and has published works on arithmetic, algebra, geometry, trigonometry, the differential and integral calculus, the theory of probabilities, the use of globes, a bibliography of arithmetical books from the invention of printing to the present time, and a work entitled the "Book of Almanacs," by which the full almanac of any year up to A. D. 2000, in either the old or new style, may be turned to at once. He furnished many articles on mathematics and astronomy to the "Penny Cyclopædia," was a contributor to the publications of the society for the diffusion of useful knowledge, and is the author of many papers in the transactions of learned societies. His work on "Formal Logic" (1847) occasioned a controversy with Sir William Hamilton, as to which of them was the discoverer of a certain new principle in the theory of syllogisms. Mr. De Morgan has also been a prominent writer in favor of the system of decimal coinage.

DEMOS (δημος), a Greek word, meaning people, and also found in the compound word democracy, meaning rule of the people. It was also the name applied to the 100, in later times 177, smaller districts into which Attica, including Athens, was divided, and 10 of which formed a *phyle*. Each demos had its own municipal officers, its assemblies, and even separate religious usages. The demarch was the representative of its interests. The chief of the executive summoned the assemblies, and had the management of the public estates and police.

DEMOSTHENES, the most illustrious of the Athenian statesmen and orators, was born in Pæania, one of the δημοι, or districts, of Attica, a few miles from the city of Athens, in the interior, on the east side of Mt. Hymettus, near the present village of Liogesi. His father was an Athenian citizen of the same name; his mother was a daughter of Gylon, also an Athenian, who, having been exiled from Athens on a charge of betraying Nymphæum to the enemy, established himself near the Bosporus, and married a woman of that neighborhood, probably the daughter of a Greek settler. There were two daughters of this marriage, both of whom were sent to Athens by their father, and married to Athenian citizens, one to Demochares, father of Demochares the orator, and the other, Cleobule, to Demosthenes, the father of the subject of the present notice. The date of the birth of Demosthenes is uncertain. The statements vary from 385 to 381 B. C. The received opinion now is in favor of 385. Demosthenes and a younger sister were left orphans by the death of their father, he at the age of 7 years, and the sister at the age of 5. A considerable fortune, consisting partly of capital, and partly of a manufactory of bedsteads and cutlery, was left in charge of 3 guardians, Aphobus, Demophon, and Therippides. Under a provision of the Attic law, it was stipulated by the will of the elder Demosthenes that Aphobus should marry the widow, with a dowry of 80 minæ ($1,533); that Demophon should marry the daughter, when she reached the proper age, with a dowry of 2 talents (about $2,000); and that Therippides should receive the interest of 70 minæ ($1,166 62, at 12 per cent., the legal rate at Athens, $139 99 annually) until the son should come of age. The whole estate was valued at something more than 14 talents (about $14,000), which made, according to the standard of those times, a handsome fortune. The guardians were unfaithful to their trust, and not only failed to comply with the provisions of the will in the matter of the marriages, but squandered a large part of the property, or appropriated it to their own use. Instead of receiving his fortune, largely increased, as it should have been, when Demosthenes attained the legal age he found it reduced to 70 minæ. The early education of the future statesman was not neglected. According to his own assertion, in the oration on the crown, he received the literary training which was suitable to his rank and fortune. Several of the most eminent men of his age

are mentioned as his teachers, and among them Plato, Isocrates, and Isæus. There is considerable doubt with regard to the first two, but the influence of Isæus is thought to be perceptible in the style of the earliest speeches, especially of those delivered in the suit against the guardians. On coming of age, in 366, Demosthenes commenced legal proceedings for the recovery of his property. The case was not finally decided until 2 years later, although the diætetæ, or board of arbitrators, by whom the case was twice examined, had rendered a decision in favor of Demosthenes. In the year 364 Demosthenes brought an action against Aphobus alone, before the archon. Aphobus was condemned to pay 10 talents ($10,000). The pleas of the young orator in these trials are preserved. They are models of clear statement, logical argument, and close application of the principles of the law; but they show scarcely any traces of that vehement and overpowering oratory for which Demosthenes was afterward so distinguished. They give us a favorable opinion of the discretion of the young man, and of the calm, judicial character of the court. The prosecution of the guardians brought upon Demosthenes the hostility of Midias, a rich and powerful citizen, who manifested his insolence and hatred, and his disregard of the laws, by a series of outrages, public and private. He forced his way into the house of Demosthenes and insulted his family, for which the latter prosecuted him and obtained a verdict (361); but Midias found pretexts for evading the payment of the penalty. In 354 Demosthenes came forward and, with great public spirit, offered to assume the cost of the *choregia* of his tribe, which had for the two preceding years neglected to make the usual provision for the lyrical, musical, and dramatic entertainments at the Dionysian festival. Midias showed his malignant disposition by every species of impertinent annoyance, and he finally proceeded to open violence, by entering the goldsmith's shop and endeavoring to destroy the golden crowns which Demosthenes had provided for his chorus, by inflicting blows upon Demosthenes in the orchestra, while he was performing his duties in the sacred character of choragus, and by tearing the festal robe which he wore on that occasion. Demosthenes brought an action against him, first under the form of προβολη (a process like the modern inquest before the grand jury), before the people, who decided that there was a sufficient ground for referring the case to one of the courts. Whether it ever came to trial is doubted. Midias endeavored to intimidate Demosthenes, but without success; it is asserted, however, by Plutarch that he finally consented to accept 30 minæ, and to withdraw the accusation. Æschines, in the oration against Ctesiphon, reproaches Demosthenes with having accepted money for blows; but Mr. Grote is of opinion that the trial actually took place, and the language of the oration itself seems to imply that all offers of compromise were rejected. The date of these transactions is 353 B. C. Demosthenes had already, two years before, delivered the oration against the law of Leptines. This oration is of great importance as illustrating the high moral principles which Demosthenes applied to public no less than to private conduct. In it the orator discusses with consummate ability the whole doctrine of the sacredness of the public faith and the inviolability of contracts. In the same year he delivered the oration against Androtion, and in 353 that against Timocrates. In 354, having been appointed by lot a member of the βουλη, or senate, he passed the scrutiny required by law, in spite of the opposition of Midias and his party. In the following year he was chief of the *Theoria*, or state deputation sent from Athens to the festival of the Nemean Zeus. He took an active part at this time in the public debates on questions of foreign policy. He opposed, but not successfully, the expedition to Eubœa in 354, and delivered an able oration against the scheme, then much favored by the political leaders of Athens, of making war against Persia (περι συμμοριων). In the following year he delivered the oration in behalf of the Megalopolitans, and in opposition to the request of the Spartans for aid in conquering them. The relations between the states of Greece and King Philip of Macedon called the genius and eloquence of Demosthenes into fuller play. That ambitious monarch aimed at the subjugation of the Hellenic world as a preliminary step to the conquest of Asia. He was a man of great talent, craft, and subtlety, and not destitute of a taste for the intellectual culture which distinguished the Hellenic name. The Athenians had colonial possessions along the north-western coast of the Ægæan sea, in the neighborhood of the territories of Philip. As early as 358 B. C. he had commenced a series of encroachments, which brought on a state of hostilities between him and the Athenians. He gained possession of Amphipolis, Pydna, Potidæa, and Methone. Demosthenes early saw through his designs, and had the courage to set himself in stern opposition to them. He felt the necessity of union among the Grecian states, and urged every consideration that patriotic ardor and unsurpassed ability suggested, with a perseverance that no fatigue could wear out, and a courage greater than that shown by the warrior on the field of battle. The Philippics, so called because they are aimed against the policy of Philip, are animated by the loftiest spirit of devotion to his country, and are among the most brilliant specimens of his eloquence. But the demoralized condition of the states, the corruptibility of the public men, the fondness for pleasure, the reluctance to submit to the hardships and discipline of former times, made his efforts unsuccessful, except for brief moments of alarm, and he failed to bring about a permanent union. The first Philippic was delivered in 352. In 349 Philip attacked the Olynthians, who had made a treaty with Athens. They sent embassies to

Athens, imploring aid against Philip, and Demosthenes supported their cause by delivering the three admirable Olynthiacs, which roused the Athenians to vigorous efforts to save them. These efforts, however, were not sufficient, and finally Olynthus fell into the hands of Philip, through the treachery of Lasthenes and Euthycrates. The town was destroyed, and the men, women, and children sold as slaves. During the Olynthian war Philip had thrown out hints of a desire to make a treaty of peace and alliance with Athens. On the motion of Philocrates, an embassy was sent to open negotiations with the king. Philocrates, Æschines, and Demosthenes were members of the embassy. Philip appears to have evaded their demand that Phocis, then in alliance with the Athenians, should be included in the treaty. The ambassadors returned, and with them came ministers from Philip. The terms of the peace were discussed in two assemblies of the people, and were finally agreed to on the part of the Athenians, the customary oath having been given to the ambassadors. A second embassy, of which Æschines and Demosthenes were again members, was sent to Philip, under instructions to make all haste to receive the oaths from him; to go wherever they should learn that Philip was at the moment of their arrival, in order that as short a time as possible might intervene, because it was apprehended that Philip would not cease his encroachments until the treaty was completely ratified. But instead of going to Macedonia by sea, they took the longer way by land; instead of finding Philip at once, they waited 3 months for his return from an expedition to the Bosporus in which he was then engaged; and finally they allowed him to defer taking the oaths until he had completed his preparations against the Phocians. They accompanied him on his march into Thessaly, and the oaths were not administered until they arrived at Pheræ. The Phocians were excluded from the treaty. The ambassadors having returned to Athens, Demosthenes accused his colleagues of treachery and of being bribed by the king. Philip's object was accomplished. He passed through Thermopylæ, and conquered Phocis without resistance. The oration on the peace was delivered in 346. From this time Demosthenes was the head of the anti-Macedonian party, and the vehement political antagonism between him and Æschines, whose oratorical ability made him the leader on the other side, commenced. The oration *περι παραπρεσβειας* (the corrupt conduct in the embassy) belongs to the year 343. Philip continued his intrigues in the mean time in the Peloponnesus, and Demosthenes was unwearied in his labors to thwart them. He went on embassies to the several states, and employed all his powers of argument, persuasion, and denunciation. Philip sent a deputation to Athens, charging the Athenians with favoring the Spartans in their designs against the liberties of the Peloponnesians. An assembly was called, Philip's ministers were heard, and in the discussion of the answer to be made, Demosthenes (344) delivered the second Philippic. In the following year Philip took Halonesus from the pirates. The Athenians claimed it as an ancient possession of their own. Philip, denying their right to it, offered it to them as a gift; and it was on this occasion that the oration *περι Ἁλονησου* was delivered, though it is doubtful whether this is a work of Demosthenes. The Athenians now made vigorous efforts to counteract the schemes of Philip in Acarnania, in the Peloponnesus, and in Thrace. Philip again complained of their course, and in this year, 342, Demosthenes delivered the oration on the Chersonesus, and the 3d Philippic, a most vigorous and daring attack. Demosthenes next caused the expulsion of the tyrants who had been established and supported by Philip in Eubœa. In 340, the Athenians, under the influence of Demosthenes, took the most energetic measures to relieve Byzantium, which the king was besieging. They sent a fleet which compelled him to withdraw, without accomplishing his purpose. In the same year he introduced a reform into the naval system, by which the burdens of this department of the public service were more equitably distributed, and its efficiency increased. At the Amphictyonic assembly, held at Delphi in the spring of 340, Æschines proposed a decree against the Locrians of Amphissa, for having sacrilegiously occupied a portion of the lands belonging to the temple. The Amphissians forcibly resisted the execution of the decree, and an extraordinary meeting of the Amphictyons was summoned to consider what should be done. Demosthenes, foreseeing the evil consequences likely to result from such a step, persuaded the Athenians to send no deputies to the meeting. The assembly met, declared war against the Amphissians, and placed Cottyphus, an Arcadian commander, at the head of the Amphictyonic forces. But many causes conspired to render the undertaking a failure, so that in the following year, at the regular meeting of the assembly, the partisans of Philip were sufficiently powerful to supersede Cottyphus by appointing Philip in his place. This gave him the opportunity he had long desired, of marching with a strong force into the heart of Greece. He occupied at once the important post of Elatea. The news of this movement, arriving at evening, caused the greatest alarm at Athens. An assembly was called early the next morning, and all business was suspended in the Agora. In the midst of the universal dismay, Demosthenes took the bema, and in a powerful speech, the substance of which he recapitulates in the oration on the crown, advocated an alliance with Thebes, as the only means of warding off the impending danger. The proposal was carried without a dissenting voice, and Demosthenes himself immediately went to Thebes as head of the embassy. The alliance was concluded, and the united armies marched northward to encounter Philip. The

great defeat of Chæronea (338) struck a disastrous blow, and overturned the hopes of the patriotic party. Yet Demosthenes did not lose the confidence of the country. With a just pride, he relates that, in all the freshness of their sorrow, the people appointed him to deliver the funeral oration over the remains of those who had fallen on that disastrous day. He was also charged with the duty of superintending the fortification of the city, in anticipation of an immediate attack. But his antagonists and enemies failed not to seize the opportunity of assailing him by every form the laws of Athens allowed, and he was daily harassed by the vexatious annoyances of such contemptible characters as Sosicles, Diondas, Melanthus, and other *sycophants*, with whom the city swarmed. To put an end to this warfare, and to test the strength of public feeling in favor of the great orator, Ctesiphon, a political friend, not otherwise known to history, introduced into the senate a resolution to confer a golden crown on Demosthenes as a suitable acknowledgment for his patriotic spirit and his public services. Before the proposition could become a law, it was necessary to pass it through the popular assembly, and in the interval any citizen might prosecute the author of it by an action called γραφη παρανομων, or indictment for illegal propositions. Æschines accordingly came forward and arrested the proceeding by prosecuting Ctesiphon. Technically the accused party was Ctesiphon, but in reality Demosthenes was put on trial for the whole of his political life. For some reason, not clearly explained, the trial did not take place within a year, as the Attic law apparently required. It was postponed 8 years, and finally was held in 330. Demosthenes appeared in the formal character of counsel for Ctesiphon, but in reality, of course, in his own defence. The orations delivered by the rival statesmen were elaborated to the highest point of their abilities, and must be considered their masterpieces; but that of Demosthenes, in force and cogency of argument, in severity of invective, in loftiness of ethical spirit, and in ardent patriotism, far surpassed the oration of Æschines. The result was remarkable. Æschines exposed himself to the penalties of malicious prosecution, inasmuch as he failed to obtain a fifth part of the votes. In consequence of this he left Athens, and never returned. King Philip was assassinated in 336, two years after the battle of Chæronea, and 4 years before the trial on the crown. This event led Demosthenes to renew his efforts to unite the Grecian states against Macedon. But the unexpected vigor of the youthful Alexander quenched his kindling hopes. An embassy was sent from Athens to sue for peace, and Demosthenes was one of those selected for this painful duty. He set out upon the mission, but after proceeding part of the way, his feelings overcame him, and he returned. A false report of the death of Alexander caused another rising among the Greeks, and Demosthenes, at his own expense, sent a supply of arms to Thebes, the only state which showed energy in the movement. But Alexander suddenly appeared before that ill-fated city, and completely subdued the spirit of the people by levelling to the ground its walls and all its buildings except the house of Pindar, 335 B. C. Soon after, Alexander started on his Asiatic expedition, having appointed Antipater regent of Macedon during his absence. Greece remained quiet for several years, but the leaders were eagerly watching every opportunity for another outbreak. Nothing of consequence occurred, however, until the arrival of Harpalus in Greece. This person had been left by Alexander in charge of immense treasures at Babylon, while he prosecuted his victorious march to India. He proved faithless to his trust, and came to Athens in 325 for the purpose of securing the protection of the city. The Macedonian regent demanded the surrender of the fugitive, and the trial of the popular leaders who were accused of having accepted his bribes. Demosthenes, being among the orators thus implicated, voluntarily offered himself for trial. His whole conduct was inconsistent with the theory of guilt, the motives of his enemies in bringing the charge were quite apparent, and there is not a tittle of trustworthy evidence against the illustrious patriot. But so great was the influence of the Macedonian faction that he was declared guilty, and thrown into prison; from which, however, he escaped, it is said, with the connivance of the magistrates. He passed the time of his exile partly at Troezen and partly in Ægina, gazing daily over the sea to the shores of his native land, which are in sight from those famous places. When the news of Alexander's death arrived, the Greeks made a fresh effort to throw off the Macedonian yoke. Demosthenes joined the ambassadors sent from Athens to the several states, and again put forth all the power of his eloquence in the cause of freedom and independence. Demon, a relative, now proposed a decree recalling him from exile. He was brought from Ægina in a public ship, and was met on landing at the Piræus by crowds of Athenian citizens and the principal magistrates, who welcomed him home with the most enthusiastic demonstrations of joy. He pronounced it the happiest day of his life. The new hopes of the Greeks met with speedy disappointment. The battle of Cranon (322) and the gradual desertion of the common cause by the confederate states, one after another, left Athens to contend single-handed with Antipater. Peace was accordingly made upon his own terms. Antipater and Craterus marched upon Athens, and Demosthenes and his friends fled. In the midst of the panic Demades proposed that they should be condemned to death, and the cowardly decree was passed. Demosthenes took refuge in the temple of Poseidon, on the little island of Calaurea; but the right of asylum could not protect him from the rage of Archias, the brutal officer of Antipater, who pursued him to his retreat.

Finding himself at the mercy of his remorseless enemies, he took poison which he had kept in a quill, and died 322 B. C. at the age of 63.—There is a statue of Demosthenes in the Nuovo Braccio of the Vatican—the noblest portrait statue in existence. It represents the orator in the act of addressing an assembly. The nervous temperament, the spare figure, the concentrated fire and energy exhibited in the face and brow, embody his character with wonderful truth. Demosthenes inherited a delicate constitution, which prevented him from engaging in the gymnastic exercises and field sports of his contemporaries; but he overcame this natural defect by the most rigid temperance in food and drink. He never indulged in wine; he was one of the earliest water-drinkers on record. He was naturally afflicted with a hesitation in speech and a shortness of breath; but by incredible force of will he cured himself of these impediments. It is said that he forced himself to speak with a pebble in his mouth, and that, in order to accustom himself to the tumults of the popular assembly, he declaimed on the beach of Phalerum to the waves as they swept along the shore. In the formation of his style he took unwearied pains. Whether he copied Thucydides 8 times, according to the tradition, may be doubted; but there can be no doubt that from his early youth to the last oration he ever spoke, he never ceased to give the profoundest study both to matter and form. He seldom or never addressed an assembly in an extemporaneous speech; his rivals and detractors used to say that his speeches smelt of the lamp. If by this charge it was meant that the style of the great orator was unduly elaborate in the structure of his sentences, or overloaded with ornaments, or artificially balanced and formal, nothing can be more untrue. The labor of Demosthenes was expended in making the thought clear, and then in making his language a perfectly transparent medium for his thought. He worked upon his orations in order to remove from his ideas every obscurity, and from his expression every thing imperfect, inexact, or ambiguous. Demosthenes was never misunderstood by his hearers. Moreover, he adapted his style with a curious felicity to his subject. In his legal arguments, it is precise, clear, technical when necessary, with no attempt at the impassioned eloquence which would be out of place on such subjects and such occasions. In his deliberative and political speeches, he blends with the closest logic every form of vehement appeal to the feelings which the moment of public peril or of patriotic excitement is fitted to arouse. He begins in a moderate tone, with the simplest language and the most undeniable propositions. He grows warm with his subject; the mighty forms of the great departed seem to rise before him; the illustrious dead start from their tombs; the august image of his beloved country is a living presence to his excited mind; his language continues simple, while his meaning becomes deeper, and his feeling more intense. Nothing can stand before such a combination of power, enthusiasm, honesty, reason, and passion. No wonder he swayed his contemporaries as no other man did. No wonder his orations are still studied, as the highest models of all that is pure and exalted in eloquence. And so it happened that his style grew better as he grew older. Compare the oration against Midias with the oration on the crown. In both the instrument is admirable, but the superior mastery displayed in the latter has been acquired by constant practice during the 24 intervening years. In private life, the manners of Demosthenes appear to have been somewhat austere. He was a man of ardent and concentrated feelings, with but little taste for the festive enjoyments in which the Athenians generally delighted. His tone of sentiment was lofty and pure; his domestic life was as stainless as his public life was incorruptible. In all the virtues of the republican citizen, he left an example which none of his countrymen ever surpassed, and which the men of other races and after ages can never cease to venerate. Athens, his beloved city, is again redeemed to letters, art, and freedom. The Bema still stands, venerable with the associations of ancient glory. The Propylæa and the Parthenon, splendid and pathetic in their ruins, are the more grand and imposing because his eye rested upon them, and his voice appealed to them in the moments of his country's greatness. Across the Saronic gulf, on the little island of Poros, the ancient Calaurea, are traces still of the temple of Poseidon, sacred to memory as the last resting place of the hunted and wearied patriot; and the waves of that classic sea, as they gently lave the island's rocky shore, seem eternally to chant his requiem.—Of the works of Demosthenes there are many editions. One of the most convenient is that of Dobson, in the *Oratores Attici*. Others are those of Taylor, Reiske, Dukas, Bekker, Baiter, and Saupe. The orations of Demosthenes alone have been edited by Wolf, Auger, and Schaefer. Dindorf's text (Leipsic, 1825) is excellent; still better, that of Bekker in 3 vols. (Leipsic, 1855). The editions of single or selected orations are too numerous to be mentioned. For the use of the American student the oration on the crown, edited by Prof. Champlin, the popular orations by the same, and the Philippics by Prof. Smead, are the best. Dissen's *Oratio de Corona*, with a Latin commentary, is admirable. The translations in Bohn's "Classical Library" are furnished with useful introductions and illustrative essays. (See also Athens, vol. i. pp. 275–278.)

DEMOTIC ALPHABET. See Hieroglyphics.

DEMOTICA, a town of European Turkey, in Roumelia, 20 m. S. of Adrianople; pop. about 10,000. It is situated on the Maritza, at the foot of a conical hill, on the summit of which stands a citadel, wherein is a palace that was occasionally occupied by the Turkish sultans while Adrianople was the capital of their empire. Charles XII. of Sweden found a retreat in this town for some time after his defeat at Pultowa.

DEMPSTER, Thomas, a learned Scottish professor and author, born at Cliftbog, Aberdeenshire, Aug. 23, 1579, died at Butri, near Bologna, Sept. 6, 1625. He was the 24th out of a family of 29 children by the same mother, and at the age of 3 gave a proof of his literary precocity by mastering the alphabet in one hour. The brutal violence of his eldest brother, James, who ended a lawless life in the military service in Flanders by being torn to pieces by 4 horses, for an act of gross insubordination, having brought the family into disrepute at home, he went in his 10th year to the university of Cambridge, and studied for some time at Pembroke hall, whence he passed over to France. For several years he wandered from one university to another, and in 1596, being then 17 years of age, he received the degree of D.C.L., and was appointed regent of the college of Navarre in Paris. At this time, and indeed throughout his whole life, he was scarcely less remarkable for his violence and quarrelsome disposition than for his learning, and was continually involving himself in broils with professors and fellow students, being as ready to draw his sword as his pen. He soon terminated his connection with the college of Navarre, was subsequently professor for brief periods at Toulouse and Nimes, and in the early part of the 17th century returned to Scotland to recover a portion of the paternal property. Having previously espoused the Roman Catholic faith, he found little favor from his family or the Scottish clergy, and returned to Paris, where for 7 years he was connected with various colleges of the university. While occupying temporarily the office of principal of the college of Beauvais, he proved his capacity and intention to preserve discipline by causing a student of high family, who had sent a challenge to another, to be "horsed" and flogged in the presence of the whole college. The young man procured the assistance of several of his kinsmen, who were members of the king's body guard; but such was the energy of Dempster that his assailants were overpowered and imprisoned in the college belfry. Deeming it prudent after this to absent himself from Paris, he went to England, and was appointed by James I. historiographer royal. In 1615 he received from the king a handsome present in money, but his hopes of preferment being defeated by the opposition of the clergy on account of his religious opinions, he betook himself in 1616 to Pisa, where for several years he lectured on the civil law. A personal difficulty induced him to go to Bologna, where, after engaging in a more than ordinary number of disputes, he rose to great eminence as professor of humanity, was knighted by the pope, and loaded with distinctions. In the midst of this prosperity his wife, a woman of great beauty, eloped with a student, and the mental and physical suffering which he experienced in an attempt to overtake the fugitives put an end to his life. Dempster's works are exceedingly numerous, numbering probably over 50, and embrace a variety of subjects. He wrote and spoke with great facility the Greek and Latin languages, was thoroughly versed in philosophy, civil law, and history, and in such elaborate works as his *Antiquitatum Romanarum Corpus Absolutissimum* and *De Etruria Regali*, which are chiefly of an antiquarian character, evinced remarkable industry and erudition. His *Historia Ecclesiastica Gentis Scotorum*, the work by which he is now best known, is a sort of biographical dictionary of Scottish worthies, in which fable and fact are pretty equally mingled. Many names of authors who never were in Scotland are claimed as Scottish, and the history of many others who never existed is given with such particularity, that we must conclude that Dempster either wilfully fabricated his statements entire, or that his credulity was imposed upon; the latter opinion being the more probable, if the testimony of Bishop Lloyd may be credited, that "he was as well inclined to believe a lie as any man in his time." Baillet, on the other hand, accuses him of wilful forgery. He was an indefatigable student, working 14 hours a day, and possessed so extraordinary a memory that he is said never to have forgotten what he had once learned.

DEMURRAGE (Lat. *demoror*, to delay), in maritime law, the detention of a vessel beyond the time allowed by the charter party (or by custom if there is no special contract) for loading or unloading or sailing; also the compensation paid or damages claimed for such detention. It is usually stipulated in the contract between the owner of the ship and the freighter that the ship shall not be detained beyond a certain time for the loading of goods on board, or for the delivery of such goods, or for sailing. If there is no such stipulation, the time is fixed by usage, and called lay days. The claim for demurrage is reciprocal, by the owner against the freighter, and by the freighter against the owner—the latter case being, however, only for delay in sailing. Demurrage is allowed only for voluntary detention, and not for any accidental delay; as if a vessel is detained for a cargo over the stipulated time, and after sailing is driven back by a storm, which would have been avoided if she had started at the time appointed, no damages are allowed for the incidental delay. Yet it would perhaps be otherwise if by the detention a further delay is caused by any thing which could be foreseen, as a periodical wind, or the freezing up of a harbor, or the like. In inland transportation, where the latter cause of delay most frequently occurs, as upon rivers or canals, the rule is that the carrier is not responsible for the delay when there has been no fault on his part, but is entitled to deliver the cargo after the breaking up of winter, and earn the entire freight; or if the freighter elect to take the goods at the place of detention, he must pay *pro rata itineris*. But if there has been voluntary delay by either party, in consequence of which the vessel is frozen up by the coming on of winter, he is responsible to the other for

damages; but the measure of such damages would not be according to the rule of demurrage in respect to sea vessels.

DEMURRER, in law, a suspension of the proceedings in a cause until some point is determined by the court; in other words, the interruption of the preparation for a final trial or hearing until some preliminary objection is disposed of. A demurrer is a pleading in equity as well as at law, and in both it raises a question as to the sufficiency of the case as stated by the opposite party, or some particular part thereof. At law a demurrer may be general or special; the former specifying no particular ground of objection, and therefore raising only the question of the sufficiency in substance of the pleading demurred to; the latter being a specification of certain objections to the form of the pleading. By the recent changes in the practice both in England and this country the distinction has become unimportant, as no objection can now be insisted upon under a general demurrer but what can be raised at the trial or hearing, while the special demurrer has become of comparatively little consequence by reason of the liberty of amending pleadings which is now allowed.

DENAIN, a French town, in the department of Nord, arrondissement of Douai, on the left bank of the Scheldt, which is here navigable, 6 m. from Valenciennes, 14 m. from Douai. Owing to the successful working of the neighboring coal and iron mines, the population has increased from 900 in 1826, to about 9,000 in 1852. Denain was the scene of the brilliant victory achieved in 1712 by the French under Villars over the allies.

DENARIUS, a Roman silver coin, containing at first 10, and afterward 16 asses. Also a gold coin of 25 silver denarii. The average weight of a large number of denarii shows them to have contained about as much silver as 3 half dimes of our currency.

DENBIGH, a municipal and parliamentary borough, market and co. town of Denbighshire, North Wales, built on an eminence near the centre of the vale of Clwyd, 22 m. W. of Chester, and 213 m. N. W. of London; pop. of the borough in 1851, 5,498. The principal edifices are 2 churches, a lunatic asylum, and a spacious market hall. The shoe and leather trade is the main support of the town, but Denbigh is best known as a pleasant spot for retirement. Denbigh castle, a magnificent edifice, parts of which are well preserved, is supposed to have been built by Henry Lacy, earl of Lincoln, who received the lordship of this place from Edward I. Edward IV. was besieged in it by the army of Henry VI., and Charles I. took refuge here after the battle of Rowton Moor in 1645. During the civil war it was garrisoned by royalists, but after a siege of two months surrendered to the parliamentarians by order of the king. Its walls and defences were blown up after the restoration of Charles II.

DENBIGHSHIRE, a maritime co. in the N. of Wales, bounded N. by the Irish sea, and bordering on England; area, 603 sq. m.; pop. in 1851, 92,583. Its surface is much diversified. There are some level tracts in the N., but along the E. and W. borders extend mountain ridges. The valleys and level tracts are remarkably fertile, producing grain, beans, and peas; the uplands yield some crops of barley, oats, and potatoes, but are mostly occupied by pastures; black cattle, sheep, and goats are reared in great numbers, and excellent cheese is made. Among the minerals are coal and iron, both very valuable, lead, slate, freestone, and millstone. Immense quantities of limestone, used for fluxing ironstone, are exported into Staffordshire, and the yield of one quarry, near Llangollen, is said to be sometimes between 70,000 and 100,000 tons in a single year. The principal rivers are the Conway, the Dee, and the Clwyd, none of which are navigable within its borders. It has no seaport, and its chief channel of transportation is the Chester and Holyhead railway, which crosses it near the coast. The Chester and Shrewsbury railway runs S. about 14 miles, just within its E. boundary. A branch of the Ellesmere canal traverses the vale of Llangollen. Chief towns, Denbigh, Ruthin, and Wrexham. Before the Roman conquest Denbighshire was the territory of the Ordovices, and was annexed to the empire only after long struggles. It contains several interesting Roman remains. It was the scene of many a fierce contest under the Saxons and the Normans, in the wars of the roses, and in the revolution of the 17th century.

DENDER, or DENDRE, a river of Belgium, in the provinces of Hainault and E. Flanders, 53 m. long, joining the Scheldt at Dendermonde. It is made navigable by locks to Ath, 40 m., and is largely used for the transportation of coal.

DENDER, a river in Abyssinia and Nubia, tributary to the Blue Nile, which it joins 40 m. N. of Sennaar. It rises in a mountain range W. of Lake Dembea, skirts Abyssinia for about 95 m. before entering Nubia, and has a total course of about 260 m.

DENDERAH (anc. *Tentyra*), a ruined town of upper Egypt, near the left bank of the Nile, famous for its antiquities, which are among the most interesting and complete in that country. The principal building is a magnificent temple, enclosed with some other edifices, in a space 1,000 feet square, by a wall of sun-dried brick, 15 feet thick, and 35 feet high. It was dedicated to the goddess Athor or Aphrodite, or, as some believe, to Isis. Facing it there is a richly sculptured gateway in the enclosing wall, on which the emperors Domitian and Trajan, whose names occur in accompanying inscriptions, are represented in the act of worship. The portico or *pronaos* of the temple is 135 feet in width, and has 24 columns arranged 4 deep, each 32 feet high, and nearly 22 feet in circumference. The capitals have a full face of the presiding divinity on each of their 4 sides; the architrave is covered like the portal with sculptures representing a religious procession, and the projecting fillet of the cornice bears an inscription in Greek,

setting forth that the portico was added to the temple in the reign of Tiberius Cæsar, in honor of the goddess Aphrodite. On the ceiling of the portico is the famous zodiac, discovered in 1799 by the French savans under Bonaparte, and on the ceiling of one of the inner chambers there was a small and somewhat similar planisphere, which was removed to Paris in 1821. Taken as an ancient representation of the zodiac, intersecting the equator at a very different point from the present equinoxes, it was rashly considered to prove, by the procession of the equinoxes, its own date to be from 15,000 to 17,000 years B. C. All scholars are now agreed that it is not older than the Ptolemies, and that a zodiac was not used by the ancient Egyptians. Seyffarth finds in the zodiac of Denderah the planets placed in such order as to indicate the year of Nero's birth, A. D. 37; the temple having been, as he supposes, built or rebuilt under that emperor. In the pronaos or on the front of the temple may also be distinguished the names of Augustus, Caligula, Claudius, Nero, Ptolemy Cæsarion, and his mother Cleopatra. The last 2 personages are also represented by rude portraits. The interior consists of 3 large halls, an isolated sanctuary, and several small chambers. Rows of columns stand in some of the rooms, displaying on their capitals the budding lotus, and all the apartments but 2 are profusely sculptured. The roof is flat and formed of oblong masses of stone. Small holes cut in the ceiling or sides admitted the only light which the interior of this gloomy but magnificent building received, and some of the rooms on the ground floor were lighted only by the few rays which found their way through apertures communicating with the rooms above. There are 2 smaller temples of Roman date near that of Athor, one dedicated to Isis, and the other, it is said, to the evil genius, though some believe it to appertain to the great temple. Works are now established at Denderah for extracting saltpetre from the ruins.

DENDERMONDE, or Termonde, a Belgian arrondissement in the province of E. Flanders, pop. in 1857, 97,289, with a strongly fortified capital of its own name. The latter is situated at the junction of the Scheldt and Dender rivers, at a distance of 16 m. by rail from Brussels; pop. in 1857, 8,662. It contains 9 places of worship, many charitable and educational institutions, an academy of design and architecture, and several fine private collections of art. In the church of Notre Dame are 2 pictures by Vandyke and other works of art, and David Teniers was for some time a resident of the town. The surrounding country is fertile and famous for producing the finest flax in Flanders. An active trade is carried on in this article, in grain, linseed, hemp, and oil, and in the various manufactures, the most important of which are woollen cloths, cotton yarn, and lace. The town is among the oldest in Belgium, and many Roman antiquities have been found in the neighborhood. In 1667 it resisted a siege of Louis XIV. by opening the sluices. In 1706 it was taken by Marlborough, and in 1745 by the French. The present fortifications date from 1822, and the bridge over the Scheldt from 1825.

DENDROBIUM, a genus of epiphytes or parasitical plants, found chiefly in the damp tropical parts of Asia, and belonging to an order remarkable for the grotesqueness as well as beauty of its flowers. The species are numerous; and in some instances they affect dry and open places on the bark of trees in New Holland, and even on bare rocks exposed to the sun. Dr. Royle found *D. alpestre* on the Himalaya mountains, at an elevation of 7,500 feet. The flowers are generally very beautiful, varying in color from a deep yellow to nearly white. They possess a high fragrance. In cultivation they thrive best when planted in pots filled with earth, but require an artificially elevated temperature to insure success.

DENGUE, called also Dingee, Dunga, Dandy, Bouquet Fever, Bucket Fever, Breakbone Fever, &c., a peculiar febrile epidemic, which at varying periods has pervaded the East and West Indies and the southern and middle states of the United States. Its first known appearance was in 1780, when it broke out at Philadelphia suddenly in the autumn, and raged for 2 or 3 months. Both sexes and all ages were affected by it, and in the district where it occurred hardly any one was exempted from its attack. It was named by the people, Dr. Rush states, the breakbone fever. Its next appearance was at Calcutta in 1824–'5; here it is very fairly described by Dr. Mellis. In 1826 it seems to have occurred in a mild form at Savannah, and perhaps elsewhere. In the autumn of 1827 it appeared in the West Indies, occurring as before as a universal epidemic. In St. Thomas the negroes gave it the name of the "dandy fever," from the stiff gait and appearance of those affected by it. When it appeared in Cuba this name, in undergoing the Spanish pronunciation, was changed into dunga or dengue, which it has since retained. It appeared again at Savannah in 1827, and in the autumn of 1828 raged through most of the southern cities. It disappeared in the winter. A few cases were seen in 1831. In 1844 it appeared at Mobile, and in 1848 at Natchez. In 1850 it again spread over the southern states, and presented the same characteristics as in the previous epidemics. The usual symptoms of dengue are pain, stiffness and swelling of some of the smaller joints, usually of the hand or foot, or of the muscles of a limb, stiffness of the neck, aching of the back and loins. These symptoms are soon followed by fever, headache, suffusion of the eyes, full, quick, frequent pulse, hot, dry skin, restlessness and thirst. The fever seldom remits, but generally declines and disappears on the 2d or 3d day. At this time the skin loses its dryness, and abundant perspiration takes place, with considerable relief of the pains in the joints; during this deceptive lull of the disease many consider themselves recovered, but soon

discover their error, as usually on the 4th day a disturbed and irritable condition of the stomach, vomiting, languor, lassitude, and debility, occur. On the 5th or 6th day an eruption appears, relieving the lassitude and uneasiness, but bringing on a recurrence of the pains in the joints and muscles. The eruption, which resembles scarlatina in some particulars, and is accompanied with a sensation of itching and burning, usually subsides in 2 or 3 days, and is attended with desquamation of the cuticle. The arthritic pains are usually of longer duration, and often render the patient lame for some weeks. The disease is very rarely fatal. In 1780 the breakbone fever occasionally proved so, perhaps from the resort to depleting measures, which seem to be contraindicated in this disease. The treatment adopted has usually been the administration of one or more emetics or a mild purgative, followed by diaphoretics and anodynes; occasionally opium has been administered in some form to allay the arthritic pains. After the subsidence of the eruption the use of tonics, and particularly of the various preparations of cinchona, is indicated.

DENHAM, Dixon, an African traveller, born in London, Jan. 1, 1786, died at Sierra Leone, June 8, 1828. He served with credit throughout the Peninsular war, and at Waterloo. In 1822 he joined Clapperton and Dr. Oudney in their exploring expedition. Setting out from Tripoli, the travellers crossed the desert and reached Lake Tchad, the coasts of which to the west and north were examined by Denham. He was separated from his companions, and after great sufferings returned to England in 1825. The result of their travels was published in 1826 under the title of "Narrative of Travels and Discoveries in Northern and Central Africa, in the years 1822, 1823, and 1824." Soon afterward Denham was appointed lieutenant-colonel, and superintendent of the liberated African department of Sierra Leone, and in 1828 governor of the colony, but died in the same year.

DENHAM, Sir John, an English poet, born in Dublin in 1615, died in 1688. In 1641 he published "The Sophy," a tragedy which was praised by Waller, and had an immediate success, and in 1643 appeared his poem "Cooper's Hill," on which his fame rests. The following two famous lines occur in the apostrophe to the river Thames, in that poem:

> Though deep, yet clear; though gentle, yet not dull;
> Strong without rage, without o'erflowing full.

DENINA, Giacomo Maria Carlo, an Italian historian, born at Revello, Piedmont, Feb. 28, 1731, died in Paris, Dec. 5, 1813. He took holy orders, acted as professor at Pinerolo and Turin, was subjected to persecutions on the part of the Jesuits, repaired (about 1782) to Berlin, in compliance with an invitation of Frederic II., for the purpose of writing a history of the German revolutions (which appeared at Florence, 8 vols., 1804), and wrote there several other works relating to the king himself, and to Russian literature, also an effusion in praise of Peter the Great (*La Russiade*, Berlin, 1790; written in French, as well as some of his other works). While at Mentz in 1804, he was introduced to Napoleon, to whom he dedicated his *Clef des langues* (Berlin, 1804), and who shortly afterward appointed him imperial librarian at Paris. Denina wrote many other literary, critical, and historical works. One of them (*Discorso sopra le vicende della letteratura*, 2 vols., Turin, 1761; 4 vols., Berlin, 1792–1811; German translation, 1785–'88) displays considerable bibliographical erudition in treating of the progress of the literature of various European nations. But his literary fame rests chiefly upon his great work on the revolutions of Italy (*Istoria delle rivoluzioni d'Italia*; last edition, 5 vols., Venice, 1800), translated into several European languages, containing a general history of that country from the time of the Etruscans down to 1792. He left in MS. 3 vols. of a history of Piedmont, which have not been published in Italian, but have appeared in a German translation (*Geschichte Piemonts und der übrigen Staaten des Königs von Sardinien*, Berlin, 1800–'3).

DENIS, Saint, apostle and first bishop of Paris in the 3d century. He was one of a company of missionaries who, after the persecution of Severus, were sent from Rome, about 250, to revive the drooping church in Gaul; and after preaching in various parts of that country and suffering much at the hands of the pagans, he arrived at Lutetiæ or Paris, where he made many converts. He built a church there, and made it the seat of his bishopric. During the persecution under Aurelian he was condemned to death by the Roman governor Pescennius, and with a priest named Rusticus, and a deacon Eleutherus, was beheaded in 272. The bodies of the martyrs were thrown into the Seine, but were recovered by a Christian woman, Catulla, who caused them to be interred near the scene of the execution. A chapel was built over the spot, and after it had fallen to ruin was replaced by St. Genevieve with a church in 469, which was afterward united to the famous abbey of St. Denis. A number of French churches are said to have been founded by this saint or his companions; he became the patron of the kingdom, and his name served as a war cry to the French, who used to rally in battle at the words *Montjoye Saint Denis*. His festival is kept Oct. 9. The popular belief that after his decapitation he walked about with his head in his hands, may have originated in the ancient paintings, which represented him so engaged, as an emblem of the manner of his death.

DENIZEN, in English law, an alien born who has received by letters patent from the king certain privileges belonging to natural born subjects. Thus he may take lands by purchase or devise, but not by descent. In American law there is no middle class of this kind between aliens and citizens, unless we may designate as such those who have declared an intention to become citizens, but have not become fully naturalized under the laws of the United States. In

some of the states, by statute, such persons are allowed to take and convey real estate, the difference between them and aliens being that, although the latter can take real estate and hold it until some proceeding is taken by public authority to divest his title, commonly called office-found (*i. e.* an inquest by official action), yet upon such proceeding being had, the land would escheat to the state although the alien should have conveyed to another. Another signification is sometimes attached to the term, in a more popular sense, though it is also to be found in some law writers, viz., a resident. This meaning is not wholly inconsistent with the other, as it may at an early period, when the doctrine of citizenship was not well settled, have been understood of the children of aliens born in England. By the present law of that country such children are recognized as subjects, except in certain cases, as the children of persons representing or in the service of foreign governments who are temporarily in England. The same rule is recognized in the United States, and as a consequence it was thought necessary to provide by law that the children of Americans born abroad should be held to be American citizens.

DENMAN, Thomas, lord chief justice of England, born in London, July 23, 1779, died of apoplexy, at Stoke Albany, Northamptonshire, Sept. 22, 1854. The only son of an eminent physician and medical writer, he was graduated in 1800 at St. John's college, Cambridge, was called to the bar in 1806, returned to parliament for Wareham at the general election of 1818, and in 1820 for Nottingham. In the latter year he took a distinguished part as solicitor in the trial of Queen Caroline. In 1822 he was appointed common serjeant of the city of London; from 1830 to 1832 he officiated as attorney-general; in March, 1834, he was raised to the peerage, and from 1832, when he retired from parliament, until 1850, he was chief justice of the king's bench. His high personal character, his great abilities as a lawyer and magistrate, and his zeal in behalf of the abolition of slavery and of various liberal measures, gained for him a distinguished place among the chief justices of England.

DENMARK (Dan. *Danmark;* Ger. *Dänemark;* Fr. *Danemark*), "the land or mark of the Dane," called also the *Danske Stat*, "states of Denmark," a kingdom in the north of Europe, between lat. 53° and 58° N., long. 7° and 13° E., bounded N. by the Skager Rack, N. E. by the Cattegat, E. and S. E. by the Sound and the Baltic, S. by the free states of Lübeck and Hamburg, the grand duchy of Mecklenburg-Schwerin, and the kingdom of Hanover, and W. by the German ocean. It consists of the peninsula of Jutland, the islands of Seeland, Funen, Laaland, Falster, Langeland, Alsen, Möen, Samsöe, Läsöe, Femern, Bornholm, and many smaller ones, and the duchies of Schleswig, Holstein, and Lauenburg; beside which it possesses the Färöe islands, Iceland, Greenland, and the islands of Santa Cruz, St. Thomas, and San Juan, in the West Indies. The following table shows the population of Denmark proper in 1858, and of the duchies and colonies in 1855:

Circles	Area in sq. m.	Population.
Copenhagen	2,833	143,591
Seeland and Möen		400,166
Bornholm	213	28,949
Funen and Langeland	1,284	196,811
Laaland, Falster, &c.	647	84,096
Jutland	9,696	646,237
Duchies.		
Schleswig	3,545	395,860
Holstein	3,269	523,523
Lauenburg	413	49,475
Colonies.	21,900	2,468,713
Färöe islands	395	8,651
Iceland	38,200	64,603
Greenland	384,000	9,892
West India islands	110	37,137
Total	445,705	2,588,996

The sea-coast of continental Denmark, extending about 460 m. along the German ocean and the Skager Rack, and 650 m. along the Cattegat, the Little Belt, and the Baltic, is generally low, flat, and sandy. The W. coast of Schleswig is protected from the ocean by dikes, but the E. coast of that duchy and the shores of some of the islands present abrupt chalk or limestone cliffs. The fiords, or arms of the sea which indent the coasts, are among the most remarkable natural features of the kingdom. The Lym fiord, which entirely insulates the N. part of Jutland, occupies nearly 252 sq. m. It was formerly separated from the German ocean by a narrow strip of land, through which in 1825 the sea broke in 2 places. The Ringkiöbing and Ise fiords are also notable for their size; and the Kieler fiord, in the duchy of Holstein, forms the spacious harbor of Kiel, in which the British fleet anchored in 1854. The lakes of Denmark are numerous, and some contain excellent fish, but all are small. With the exception of the Elbe, which forms part of the S. boundary, there are no large rivers, the most considerable being the Eider, 105 m. long, navigable almost to its source, and flowing into the German ocean; the Trave, 65 m. long, and also navigable, flowing into the Baltic; and the Guden, 80 m. long, discharging itself into the Cattegat. The broad passage called the Great Belt separates the islands of Seeland and Funen, and the Little Belt the latter from the coasts of Jutland and Schleswig. The surface of the kingdom is an almost unbroken plain, elevated in most places but a few feet above the ocean, and in others depressed below the level of the sea. The N. W. part of the peninsula is a desolate region, over which tempests and drifting sands sweep with destructive fury. To consolidate the soil and break the force of the winds, various kinds of trees and shrubs, of which the improvidence of former generations had nearly stripped the country, are now planted here, and their destruction is forbidden under severe penalties. From the promontory of Skagen at the extreme N., a low barren ridge runs through continental Denmark into Germany, the highest summit at-

taining an elevation of about 1,200 feet. The island of Funen contains a range culminating at the height of 400 feet, called the Funen Alps, and Seeland has eminences 560 feet above the sea. All the rocks belong to the tertiary and upper secondary formations, and, with the exception of the hill of Gipsberg, which seems to have been upheaved from far below the surface, have apparently been deposited from water in regular strata. Several species of chalk are found, above which is an extensive bowlder formation traversed by seams of lignite, and above this again beds of clay and marl are spread over a large part of the country. The soil is almost wholly alluvial, and in the E. part of Jutland and in the duchies is covered with rich vegetable mould. The N. and W. parts of Jutland, however, are sandy wastes, and for a distance of 200 m. along the coast there is an almost continuous line of sterile flats called *klitten*. The larger islands are fertile and characterized by a rich marshy loam, interspersed with occasional tracts of moor. The climate, owing to the low and almost insulated position of the country, is temperate and humid, the cold being greatest in Jutland. The winters are seldom severe for that high latitude, the mean temperature from November to March ranging from 7° to 25° F., though in January and February the thermometer sometimes falls 22° below zero. From June to the middle of August the mean temperature ranges from 59° to 73°, and the extreme heat is 89°. The shortest day is 6½ hours, and the longest 17½. The weather is very variable, but thunder storms are rare. Violent winds, rains, and fogs frequently occur, and drought is seldom felt. The mineral products are of little value, and are confined principally to fullers' earth, potters' and porcelain clays, freestone, and salt. Coal mines were formerly worked in the island of Bornholm, but are now abandoned; there is one establishment for making salt in Holstein; peat is abundant, and amber is collected on the shore of the German ocean. The fine forests which once adorned Denmark have decayed or been cut down, and of the scant woods which remain, chiefly on the E. coast of Jutland and in the island of Funen, ¼ is the property of the crown. Pine, beech, oak, and birch are the principal varieties of timber. The alimentary crops are wheat, rye, oats, barley, buckwheat, peas and beans, potatoes, other common vegetables, and fruits. The average annual yield of wheat is estimated at 3,200,000 bushels, rye 1,280,000, oats 3,600,000, barley 16,000,000, buckwheat 1,000,000, peas and beans 2,000,000, and potatoes 2,250,000 tons. About 450,000 lbs. of tobacco are produced, 2,500 cwt. of hops, and large quantities of rapeseed, hemp, and flax. A great proportion of the land is devoted to pasturage, and the rearing of horses and cattle forms an important branch of industry, and a considerable source of national wealth. Cattle are valued chiefly in connection with the dairy, from which is drawn the principal revenue of the farm. The breeds of horses are excellent for cavalry or for draught; sheep are kept more for their milk (of which butter is made) and their flesh than for their wool; there are 3 species of swine, and poultry of all kinds abound. The rivers and fiords furnish valuable fish, among which are the herring, cod, mackerel, and salmon.—The inhabitants of Denmark are of 5 distinct races, viz.: 1, the Danes, who occupy Jutland, Seeland, and part of Schleswig; 2, the pure Germans of Holstein, Lauenburg, and the greater part of Schleswig; 3, the Frieslanders, who dwell on the W. coast of Schleswig, and the small islands in the German ocean; 4, the Angles, inhabiting the regions between the Flensburg fiord and the Sley; and 5, the Norwegians of Iceland and the Färöe islands. Of these, the first comprise nearly ⅔ of the entire population. About ⅔ of the inhabitants use the Danish language, and the rest speak German. The Danes are strong, well made, patient, industrious, and contented. They have regular features, blue eyes, and light hair. They make bold seamen and brave soldiers, but have little enterprise. The proportion of paupers is 3 per cent., only ⅓ of that of Holland. About 60 per cent. of the population are engaged in agriculture, which is conducted with great industry; but from the subdivision of land into small farms, the possession of a few acres being the summit of a Danish husbandman's ambition, it is seldom carried on with appliances requiring much outlay. The art of husbandry, however, is steadily progressing, and Holstein and Lauenburg, notwithstanding heavy dues and taxes, are tilled with considerable skill. About ⅓ of the available land are devoted to useful purposes. Both agricultural and industrial resources are more fully developed in the duchies than in Denmark proper, and Holstein is probably the most flourishing part of the whole kingdom. Manufactures generally are in a backward state; they comprise silk, linen, woollen, and cotton goods, leather, lace, gloves, straw hats, sail cloth, thread, paper, soap, glass, earthenware, plated ware, iron ware, saltpetre, gunpowder, arms, refined sugar, tobacco, soda, potash, brandy, and malt liquors. The peasantry make most of their wearing apparel and domestic utensils with their own hands.—Lying between two seas, in easy communication with all the maritime nations of Europe, commanding the entrance to the Baltic, abounding in good harbors, and possessing a large body of hardy and excellent seamen, Denmark enjoys unrivalled facilities for commerce, and beside its own import and export traffic, conducts a large carrying trade for other countries. The principal articles of export are grain, butter, cheese, brandy, smoked and salted meats, horned cattle, horses, skins, hides, whale and train oils, fish, cider down, woollens, tallow, and bristles. Among the imports are wines, salt, drugs, silk, wools, cotton, cotton fabrics, timber, coal, iron, colonial produce, spirits, glass, flax, hemp, coffee, rice, tobacco, and whalebone. The value of imports from all countries in 1856 was

68,325,291 rix dollars ($37,373,934 U. S. currency), and that of exports 34,535,059 rix dollars ($18,880,677). The following table shows the share in the above amounts of the countries chiefly concerned in the Danish trade:

Countries.	Value in rix dollars.	
	Imports.	Exports.
Hamburg	23,051,062	9,181,784
Great Britain	12,089,628	8,442,604
Sweden and Norway	6,561,412	5,825,150
Russia	3,516,191	289,609
Lübeck	2,511,031	993,479
Prussia	1,771,445	1,727,230
South America	2,184,593	25,111
North America	107,857	29,232
West Indies (Danish and foreign)	3,457,072	293,595

The entrances at the various ports were 71,361 vessels of 1,719,643 tons, and the clearances 71,094 vessels of 1,649,339 tons. Until about the close of the 18th century the commerce of Denmark was oppressed by legislative enactments which tended more to the immediate emolument of the crown than to the general prosperity and wealth of the kingdom. Imported manufactures had to be sold at auction by the revenue officers, and the importer received the proceeds after the duties had been deducted. These duties were excessively high; monopolies were often granted to rich companies for trading even with the colonies; and heavy taxes were also laid on the domestic traffic between different provinces. But toward the year 1797 a more liberal policy began to prevail; the customs regulations assumed the form of a more permanent tariff; many of the most burdensome restrictions were taken off, and commercial treaties have since been made on a basis of reciprocity with the United States and other nations. Connected with the commercial regulations is the question of the Sound dues, which a few years ago acquired considerable prominence. The Sound is a strait leading from the Cattegat into the Baltic, between the island of Seeland and Sweden, its width at the narrowest part being about 3 m. Both coasts were once owned by Denmark, which has consequently from a forgotten period claimed the right of imposing tolls on all vessels navigating this passage. This exaction was from time to time resisted by various nations, and several obtained exemption either by payment of an annual commutation or by treaty, but at the congress of Vienna the Danish claims were generally admitted. Subsequently the question of their abolition was agitated. A meeting of representatives of several European powers was held in Copenhagen in the first months of 1856, and Denmark agreed to accept as compensation for the removal of the tolls the sum of 35,000,000 rix dollars ($19,145,000 U. S. currency), payment of which was to be apportioned among the various states interested in the trade of the Baltic. The proposal was accepted by the United States as well as other powers, and a convention between the former and Denmark was signed in Washington, April 11, 1857. Great Britain paid 28.90 per cent. of the indemnity, Russia 27.80 per cent., Prussia 12.60 per cent., and the United States 2.03 per cent. or $393,011.—The domestic shipping trade of Denmark is very large, and as no inland point is much more than 40 m. from the sea, most of the internal communication is carried on by water. There are 4 large canals, one of which, called the canal of Kiel, from the town of that name on the Kieler fiord, to a navigable part of the Eider, 23 m. distant, connects the Baltic with the German ocean, and is navigable by vessels of 150 tons. It has 7 sluices, and the same number of bridges. The Stecknitz canal, in Lauenburg, completes a chain of communication between the Baltic and the Elbe. The Daneskiold canal is in the island of Seeland, and that of Odense connects the capital of Funen with the sea. There are 3 railways, viz.: from Copenhagen via Roeskilde to Corsoer on the Great Belt; from Altona, opposite Hamburg, to Kiel, with branches to Glückstadt and Itzehoe, and to Rendsburg; from Toenningen to Flensburg, with a branch to Rendsburg. The high roads, which are wide, macadamized, and well kept, are under the care of a corps of royal engineers.—The religion of Denmark is Lutheran, but all creeds are tolerated. The national church is governed by 11 bishops nominated by the crown. It embraces almost the whole population, and has at Copenhagen a missionary college founded in 1777, and a seminary for approved candidates in divinity, beside 12 religious communities in various parts of Denmark proper and the duchies. The Jews number 4,143; Mormons, 2,044; Baptists, 1,548; Roman Catholics, 1,151; Anglicans, 140; others not of the established religion, 1,555. Great attention is paid by government to education, and there is in the ministry a department of public worship and instruction, under which are superintendents for the several divisions of the kingdom. The ministers appoint teachers and regulate the course of studies in the public schools, of which some are free. Every village has at least one school, and there are moreover 30 or 40 gymnasia, and several normal seminaries. Copenhagen and Kiel have their universities, the former attended by 1,200, the latter by 300 students. There are asylums for the deaf and dumb, and literary and scientific institutions of various kinds are established throughout the country. Every child between the ages of 7 and 14 is obliged by law to attend some school, and it is rare to meet a Danish peasant, however poor, who cannot read and write. The number of periodicals is large in proportion to the population.—The government of Denmark is a hereditary constitutional monarchy. By the constitution of Oct. 2, 1855, the king must confess the Evangelical Lutheran religion, be at least 18 years of age, and give his oath to the privy council of state that he will maintain the fundamental laws. His dignity is inviolate, and all his ordinances must be countersigned by the minister of state, who is appointed by him, and who is responsible to the king or diet before

the supreme court of the state. The king appoints officers, declares war, and concludes treaties of peace, alliance, and trade; but he cannot alienate the territory or essentially modify the political relations of the state without the consent of the diet. The legislative power is divided between the king and diet, which consists of 80 members, 20 of whom are appointed by the king, 30 by the representative assemblies of different portions of the state, and 30 by election of the citizens. It sits once in 2 years in Copenhagen; its president and vice-president are appointed by the king; and its proceedings are either in the Danish or German language. It proposes laws, which are not valid till sanctioned by the king; and taxes cannot be imposed without its consent. The supreme court of the kingdom consists of 15 members, 5 of whom are chosen from the diet, and 10 from the high courts of the country. Personal freedom, freedom of the press, religious freedom, the inviolability of private residences, and the right of public assembly, are secured. The highest court of the kingdom is the privy council of state, consisting of 5 ministers for the entire monarchy (3 for Denmark, 1 for Schleswig, and 1 for Holstein-Lauenburg), and presided over by the king. The administration of the government is carried on by 5 ministries: of foreign affairs, of interior affairs, of war, of naval affairs, and of the finances. The estimated revenue of the whole kingdom for the fiscal period of 2 years ending March 31, 1860, is $18,563,650; and the expenses, of which $875,200 were for the civil list, were estimated at the same sum. The national debt, April 1, 1858, was $62,942,196. The numerical strength of the army on a peace footing is nominally 40,000, but only 10,000 men are actually employed. The navy comprises 4 ships of the line, 9 frigates, 7 corvettes, 4 brigs, 3 schooners, 17 transports, and 78 other vessels of different kinds. The capital and principal town is Copenhagen.—There is no authentic account of the early settlement of Denmark, but the Cimbri seem to have occupied it toward the end of the 2d century B. C. In A. D. 250 the country was occupied by the Goths under the half fabulous Odin or Wodin, whose son Skiold is mentioned as first monarch of Denmark. During the 8th and 9th centuries the Danes began to acquire renown by their maritime expeditions, in which they invaded England and Scotland and conquered Normandy. In the 9th century the different states of Denmark became united under one monarch, and in 1000 and 1014 Norway and the greater part of England were added to the growing kingdom. In 1016 Canute, under whom Denmark became Christian, completed the conquest of England, where his race continued to rule until 1042. The feudal system was introduced into Denmark in the 12th century, and contests took place here between the sovereign and the barons similar to those which convulsed England during the same period. In 1387 Margaret, styled the northern Semiramis, widow and successor of Haco, king of Norway, and daughter of Waldemar III., a descendant of Canute, mounted the thrones of Denmark and Norway, and, claiming the Swedish crown also in right of her husband, vanquished a competitor in that country, and united the 3 powers by the compact of Calmar in 1397. But the Swedes always resisted this union, and after a series of contests, in which they were finally led by the famous Gustavus Vasa, seceded from it in 1523. During this troubled period the population dwindled, the seas swarmed with pirates, commerce fell away, and incessant quarrels between the king and his nobles or the latter and the clergy added to the disasters of the kingdom. After the extinction of Margaret's line in 1439, and the deposition of Eric VII., the states elected Christian, count of Oldenburg, king, from whose grandson, the ill-famed Christian II., the crown passed in 1523 to Frederic I., duke of Schleswig and Holstein. Frederic's son, Christian III., united these 2 duchies to the crown 11 years later, and divided the greater part of them between his brothers, a measure which caused a long series of disturbances. In his reign a code of laws called the "Recess of Kolding" was promulgated. In the 17th century Christian IV. sided with the Protestants in the great religious war, but was worsted by Wallenstein in 1626–'7, and compelled to sue for peace. Eleven years later commenced the first of several wars with Sweden, which lasted until 1645, and cost Denmark several extensive provinces. A few years later the Swedes under Charles Gustavus overran Holstein, crossed the frozen Belt into Funen, took Odense, and invested Copenhagen, but were successfully opposed by Frederic III. In 1658 they again besieged Copenhagen, and continued their operations until the death of Charles Gustavus in 1660, when Denmark secured a peace by the sacrifice of territory. The same year was marked by the restriction of the power of the nobility and the extension of the royal prerogative. The succession, too, which had formerly been to some extent elective, was by the commons, who sided with the king in his struggle with the nobles, acknowledged hereditary in the family of Frederic. A new war with Sweden terminated in 1669, and another was occasioned in 1699 by an attempt of Frederic IV. to invade the dominions of the duke of Holstein, an ally of Sweden. Copenhagen again became the seat of war, when the Danes, terrified by the energy of the young Charles XII., bought peace by the payment of a sum of money, and remained neutral until the disasters of the Swedes in the Ukraine tempted them to renew hostilities. The war lasted until the death of Charles XII. in 1718, after which Sweden began to decline and Denmark to pursue the wise policy of peace. By a defensive alliance, however, with Russia, Prussia, and Sweden in 1801, she involved herself in a quarrel with England, suffered severely in the naval battle off Copenhagen, and lost her colonies in the East and West Indies,

which were restored to her, however, by the treaty of peace which followed. In 1807, Napoleon having threatened to make Denmark take part in the war against England, the latter sent a large armament to the Baltic to compel the surrender of the entire Danish navy. The British forces landed near the capital, and soon forced the government to give up its fleet. A war of exasperation naturally followed. Hostilities were carried on by sea, partly at the entrance to the Baltic, partly off the Norwegian coast, the Danes fighting with spirit, and sometimes with success, and both parties suffering severely in their commerce. Denmark again lost her West India islands, and again recovered them on the peace concluded in 1814, but Heligoland and her fleet remained in the possession of her enemy. It was stipulated that Norway should be ceded to Sweden, as an equivalent for Pomerania, which province Denmark had received from Sweden, and which in 1815 she made over to Prussia, in exchange for the duchy of Lauenburg and a large sum of money. Serious complications now arose between the crown and the duchies. The population of Holstein especially sympathized more with the German empire than with Denmark, and an antipathy of races sprang up, which various political measures deepened into an alarming disaffection. A prominent subject of complaint was the royal succession. The expected extinction of the male line in the reigning family afforded a prospect of rendering the duchies independent of the Danish crown, and the project of annexing Schleswig to the German confederation was openly advocated in the provincial assembly. In this state of affairs the king issued letters patent, proclaiming that with the exception of certain parts of Holstein the laws of succession should be uniform in all parts of his dominions, the effect of which was to add greatly to the popular discontent; and when the present monarch, Frederic VII., mounted the throne in 1848, the duchies resorted to arms, and appealed to their German brethren for assistance. They were aided by Prussia, who, being pressed by the revolutionary movements of Germany, sent a large force into Schleswig, drove out the Danes, who had found little difficulty in putting down the insurgents there, and followed up her success by an invasion of Jutland. Meanwhile England and Russia interfered; an armistice was signed, Aug. 26, on terms highly displeasing to the duchies; and although Prussia undertook a second campaign in the spring and summer of 1849, Schleswig and Holstein thenceforth relied mainly on their own resources. They placed their army under Gen. Willisen, a brave and able soldier, and maintained a spirited resistance, until signally defeated at Idstedt, July 23, 1850. Prussia had now definitely withdrawn from the contest, and with Austria gave her influence on the side of Denmark. The mediating powers prepared to occupy the strongholds of the country; the duchies were forced to submit, and the question of succession was referred to a convention of the plenipotentiaries of the principal powers of N. and W. Europe. By a treaty signed by these representatives, May 8, 1852, the succession was settled upon Prince Christian of the Sonderburg-Glücksburg line and his male heirs; an arrangement which gave great dissatisfaction both to Denmark and to Schleswig and Holstein, as in the event of the extinction of this family Russia reserved the ancient right of succeeding to a portion of the duchies. The new order was announced to the diet in Oct. 1852, and was at once rejected. It met the same fate before a new assembly in Feb. 1853; but the king, feeling himself pledged to the foreign powers, resolved upon a second dissolution, and the measure was finally adopted by a third parliament, June 24.

DENMARK, Language and Literature of. The Danish language (*Danske Sprog*) is a sister of the Swedish and Norwegian, and a descendant of the *Danska* or *Norræna Tunga*, northern tongue, as the Sagas call what became the Icelandic, which is also called in Danish *gamle Nordiske*, the old northern language. After the separation of its offspring, the *Norræna* received the name of *Islenzka*, from Iceland, discovered in 860 and settled in 870, by Norwegians. The Dansk, Svensk, Norsk, with their still hale and vigorous mother in Iceland, constitute a group collateral to that of the Germanic or more southern tongues; both groups issuing from one powerful and deeply rooted trunk. Both Northmen and Germans are traceable to the regions about the Euxine, to Thrace, and eastward as far as the region of the Oxus river, where they had been connected with other branches of the Aryan family, whose most developed eastern language was the Sanscrit. Relations with the Lettic and Latin, with the Doric and Æolian dialects, and with adventitious Armenian, Finnic, and other elements, cannot be discussed here. The Mœso-Gothic, Norræna, and Anglo-Saxon are the 3 ancient branches of the Scandinavo-German stem. The branches of the Norræna are, in the order of their affinity to it, the following: that on the Färöe (sheep) isles, that of the Dalarne or dales of the Swedish highlands, the Svensk, the Dansk, and the Norsk, which last differs by a peculiar accent from the Danish. This stands in a similar relation to the Icelandic with that of the Italian to Latin; having become weaker, simpler, more vocal, and shorn of most of the original grammatical forms. It is also most affected by German influence.—Beside the literary language in Denmark proper, there are two groups of popular dialects, the first of which consists of the idioms of northern Seeland, of southern Seeland, of Fyen (Fünen), of Falster, and of Langeland, together with the very peculiar idiom of Bornholm; while the second group comprehends the North Jutic or Normano-Jutic in the N. and W. region of the peninsula, and the South Jutic or Dano-Jutic in Schleswig on the coast of the Little Belt. The dialect of Mors, near the N. coast of Jutland, is very peculiar, and that of Schonen has

become Svio-Gothic since the commencement of the 17th century. Owing to the extraordinary richness of the Icelandic in roots, the Danish abounds in compact and intuitive words for all natural objects, especially in nautical and economical, also in concise ascetic and law terms. This great store is increased by the modifying influence of prefixes and suffixes, and by the Germanic facility of combining simple words into clearly intelligible compounds. The Danish is, however, more mild than the German, having fewer aspirated and hissing sounds. Germanic elements were introduced into it in two ways, to wit: Anglo-Saxon, by the Danish invasions of and rule (Canute the Great, 1016–'35, Hardicanute, 1035–'42) in England, whence missionaries were also sent to convert the Danes; German, in consequence of the warlike expeditions of the Waldemars (1st, 1157–'82; 2d, 1202–'41; 3d, 1340–'75, &c.) and of other Danish kings, of the wars and commerce with the Hansa, of the rule of German dynasties (Eric VII. of Pomerania, Christopher of Bavaria, Christian I. of Oldenburg, 1448, and his successors), also in consequence of the journeys of Scandinavians during the 13th century and afterward, and their studies in German universities. Luther's reformation, however, exerted the greatest influence on the Danish language; although it was, independently of this event, rapidly rising in vitality and importance, probably from the same predisposing circumstances which gave birth to the general reawakening of the European mind. This is evident from Pedersèn Jertegn's *Postille* of 1518, and his version of the New Testament in 1529, both of which exhibit an energy, fulness, and flexibility of speech, that cannot be ascribed to the religious metamorphosis of the century. Obstacles to the free expansion of the national language were found in the use of the German as the court language on the one hand, and in that of the Latin as the literary language on the other. Toward the close of the 17th century the Danish, however, began to flourish again, thanks to the fashion of writing hymns in it. The inroads of French taste soon blasted this tender vegetation, and overwhelmed the language with Gallicisms in words and phrases. In the 2d half of the 18th century, German culture, becoming predominant, overcame that evil, aided by the reformatory efforts of native poets, such as John Ewald and others. The independent development of the Danish into a literary language, in the beginning of the 19th century, is due to the revival of ancient Norsk studies, as well as to its masterly management by Baggesen, Oehlenschläger, Grundtvig, &c.; so that it now stands in the front rank among the mildest and richest languages of Europe. It is spoken not only in Denmark, but also exclusively in the islands and in Jutland, and in a part of Schleswig. It is used in the churches among the Esquimaux in Greenland; as a business language on the isles of St. Croix, St. Thomas, and San Juan, and in the former Danish factories in Guinea. Well educated Icelanders and Norwegians also speak Danish.—In time the ancient 16 runes (*Runir*), brought from Thrace, were supplanted by the German angular alphabet, which in its turn was superseded by the Roman characters. At present, the Danish letters, according to Erasmus Rask and other authorities, are 27 in number, as follows: *a*, *i*, *o*, *u* (all pronounced as in German and Italian), *e* (both é and è French), *y* (u French, ü German); *b*, *c*, *f*, *k*, *l*, *m*, *n*, *p*, *t*, *v* (all as in English), *d* (of 4 kinds: final after a vowel, like the English *th* in birth; between vowels very soft; final after a consonant, as in English; after *l*, *n*, *r*, almost silent, rendering those liquids nearly double, as in *vold*, full, voll), *g* (always hard, as in go, give), *h* (always aspirated), *j* (like the English *y* in yes, aye), *r* (always rough), *s* (always hard as in son), *x* (always *ks*); the peculiar 4 vowels: å or *aa* (like English *a* in warm, or *oa* in broad), *æ* (like *ai* in sail, German *ä*), *ø* (French *eu* in *peu*), *ö* (French *eu* in *veuve*, *œu* in *cœur*). Diphthongs: *aj*, *ej*, *oj*, *uj*, *öj*; *av*, *ev*, *iv*, *ov*, *æv*, *øv* (the *j* like our *y*, and both *j* and *v* softer than before vowels, as *ja*, *va*, &c.); improperly so called, since they rather form impure syllables. The combinations *kj*, *gj*, somewhat resemble the French *mouillé* sounds, the *j* (our *y*) being very mild and liquid. The Danes have not the sounds of our *j* in jar, *ch* in chat, *sh* in shell, *th* in thick.—The accent of genuine Danish words is mostly on the radical vowel; but in many foreign words it affects the last syllable, as in French. The grammatic forms are less explicit than in the Icelandic. The definite article of adjectives is *dèt*, neuter or objective, *dèn*, common or personal, *dé*, plural; thus: *dèt skönne Land*, the fine country; *dèn gamle Stol*, the old chair; plural, *dé gamle Stole*. It is suffixed to substantives, after dropping the *d*; thus: *Land-et*, *Stol-en*, the country, the chair; but it is *ne* or *ene* in the plural, as *Lande-ne*. The indefinite article, derived from *eet*, *een*, a, one, is *et*, *n*, *en*; *e. g.*: *et Land*, a country, *en Stol*, a chair; *Lande*, countries, without the article. The declension of substantives is confined to the suffix *s* or *es* for the genitive of both numbers. The plural is indicated in 4 ways, viz.: by change of the radical vowel (as in English mouse, mice), as *Sprog*, language, *Sprøg*, languages; or by suffixing *e*, as *Land-e*; or by *er*, as *Sag*, thing, *Sag-er*, things; or by both metaphony and the suffix *er*, as *Bog*, book, *Bög-er*, books. Adjectives become neuter by the suffix *t*; thus: *stor*, Latin *magnus* and *magna*; *stort*, *magnum*; plural *store*. The comparative degree is formed by adding *re* or *ere*; the superlative by *ste* or *este*; *e. g.*: *et lærd-ere Fruentimmer*, a more learned woman; *den hvideste Farve*, the whitest color. Some of the irregulars are: *ung-t*, *yngre*, *yngst*, young, younger, youngest; *lidet*, *mindre*, *mindst*, little, lesser, least; *meget*, *mere*, *meest*, much, more, most; *mange*, *flere*, *fleest*, many, more, most; *god-t*, *bedre*, *bedst*, good, &c.; *ond-t*, or *slem-t*, *værre*, *værst*, evil or bad, worse, worst; *gammel-t*, *ældre*, *ældst*, old, &c.; *nær-t*, *nærmere*,

nærmest, near, nearer, next; *ud*, *ydre*, *yderst*, out, utter, utmost, &c. The numerals are: *eet*, *een*, 1; *to*, 2; *tre*, 3; *fire*, 4; *fèm*, 5; *sex*, 6; *syv*, 7; *aatte*, 8; *ni*, 9; *ti*, 10; *èllève*, *tolv*, *tretten*, *fjorten*, &c.; *tyve*, 20; *tredive*, 30; *fyrretyve*, 40; but the following 4 decades are peculiar: *halvtrés* or *halvtrésindstyve* (half 60 and 20) for 50; *tres* or *tresindstyve* (3 times 20), 60; *halvfjers* or *halvfjersindstyve* (half 80 and 20, only equal to 60), used for 70; *firs* or *firsinstyve* (4 times 20), 80; *halvfèms* or *halvfemsindstyve* (also unaccountable literally), 90; *hundrede*, 100; *tusende*, 1,000. *Tres*, *firs*, and *fèms* being taken for 60, 80, 100, supposing them to be doubled, the *halvtres*, *halvfjers*, and *halvfèms* are taken for 50, 70, and 90, as the decades halfway toward 60, 80, 100. The ordinals are: *det*, *den første*, the first; *det andet*, *den anden*, the other, or 2d; the rest are formed by suffixing *de* or *te*. Time (French *fois*) is *Gang*, as *anden Gang*, the 2d time, &c. The personal pronouns are: *jeg*, I; *mig*, me; *du*, thou; *dig*, thee; *han*, he; *hún*, she; *hans*, his; *hendes*, (of) her; *ham*, him; *hende*, her; *vi*, we; *vores*, ours; *os*, us; *I*, you; *eders* (*jer*), yours; *eder* (*jer*), you; *sig*, himself, herself, themselves. The demonstratives *de*, *deres*, *dem*, are used for they, their, them. *Selv*, self, selves; but *han self*, himself, means also master of the house, *hún selv*, herself, the house-lady, &c. The possessives are: *mit*, *min*, plural *mine*, my, mine; *dit*, *din*, *dine*, thy, thine; *sit*, *sin*, *sine*, its, his, her, their; *vort*, *vor*, *vore*, our, ours; *jer*, *jere*, your, yours. The demonstratives are: *det*, *den*, genit. *dets*, *dens*; plural *de*, *dem*, genit. *deres* (also used in conversation with one or more persons, like the German *Sie*, *Ihnen*, *Ihr*, you, your); *dette*, *denne*, *disse*, this, these; *hint*, *hin*, *hinne*, that, those; *saadant*, *saadan*, *saadanne*, and *sligt*, *slig*, *slige*, such. The relatives are: *der*, who; *som*, who, whom, that; and also interrogatives: *hvem*, who; *hvad*, what; *hvilket*, &c., which; *hvordant*, &c., how. Indefinite pronouns: *der*, it, there, also with passive verbs; *man* (also German, the French *on*), one, some one; *noget*, *nogen*, plural *nogle*, some, any; *somme*, some people; *intet*, *ingen*, nobody; *alt*, *al*, plural *alle*, all; *hvert*, *ethvert*, every; *hinanden*, each other; *hverandre*, one another. The theme of the verb is the imperative; the conjugation comprehends 2 orders subdivided into 3 classes each, according to the form of the past tense.

I.—Simple Order (present and past indicative, and participle past).

1st conj.
1. *Klager*, complain, *klagede*, *klaget*.
2. *Brænder*, burn, *brændte*, *brændt*.
3. *Følger*, follow, *fulgde*, *fulgt*.

II.—Complex Order.

2d conj.
1. *Beder*, beg, pray, *bad*, *bedet* or *bèdt*.
2. *Faar*, receive, *fik*, *faaet*.
3. *Lader*, load, *lod*, *ladet*.

3d conj.
1. *Slipper*, escape, slip, *slap* (plur. *sluppe*), *sluppet* or *sluppen*.
2. *River*, tear, rip, *rev* (plur. *reve*), *revet*, *reven*.
3. *Byder*, invite, *bød* (plur. *bude*), *budet*, *buden*.

The persons are distinguished by pronouns or other words; even the numbers are often alike or confounded in common speech, even when distinguished in writing. The passive voice admits of no distinction of numbers or persons, but merely of tenses and modes. It is, however, distinguished from the Germanic dialects by having a simple form in the present and past, by means of the suffix *s* or *es;* thus: *Jeg elskes*, I am loved; *jeg elskedes*, I was loved (from *jeg elsker*, I love; *jeg elskede*, I loved or have loved). The infinitive is sometimes denoted by *at*, to; thus: *at elske*, to love; the participle present by *nde* final. There are also deponent verbs, analogous to those of the Latin. The auxiliary or periphrastic verbs are: *skal*, plural *skulle*, shall; *skulde*, should, &c.; *vil*, plural *ville*, will; *vilde*, participle *villet*, would; *har* (from *haver*), have; passive *haves*, be possessed by; *er*, am; *var*, was; *vær*, be; *faar*, get; *maa*, may, must; *kan*, can, may; *tör*, dare, need; *lader*, let, cause to, &c. *Bliver*, remain, forms the passive sense; *e. g.: bliver fundet*, is found. *Har* and *faar* with an infinitive also express duty: *Jeg har at sige Dem*, I have to say (to) you. The Danish has more varieties of circumlocution than the English, and its auxiliaries are less defective. The syntax resembles that of the English. The definite article may be omitted; but it is sometimes used where the English omits it; thus: *Natur-en*, nature; *Liv-et*, life, &c. The noun which governs a genitive is usually without the article; *e. g.: Verdens Alder*, the age of the world; *et Legemes* (body) *Tyngde*, the gravity of a body; *Mange Vandes Lyll* (many waters loud), the sound of many waters. The preposition *af* is omitted with quantities, as *en Mængde Mennesker*, a crowd of people; unless the thing measured be definite, as *en Skæppe af den ny Hvede*, a bushel of the new wheat. Adjectives follow only surnames, as *Knud den Store*, Canute the Great. *De*, when used instead of thou, takes the singular of the verb, as *Gaar De paa Komedie?* Do you go to the theatre? The active participle in *ende* final is never used as a gerund, but mostly as an adjective, and the English participle in *ing* must often be rendered by the infinitive; thus: *det er næppe vord at se*, it is scarcely worth (to see) seeing. Prepositions sometimes must be translated by other words; thus: *i*, in; *i Gaar Aftes* (in yester eve's), last evening; *i Morges*, this morning; *i Aar*, this year; *i Morgen*, to-morrow, &c. *Paa*, on, upon: *paa Söndag*, next Sunday. *Ad*, to, up, of: *ad Aare*, next year. *Om*, for, about: 5 *Rigsbankdaler om Maaneden*, $5 a month, &c. We subjoin a specimen of Danish construction:

En Købmand módtog en Fem-shillings-Mynt
A merchant received (took) a five shilling coin
der ikke syntes ham at være ægte, og
(mint) that not seemed him to be good, and
spúrgde dèrfor en Sàgfører, som gik forbi
asked therefor a lawyer (sake-farer), who went by
hans Butik, hvad han meente om den.
his shop, what he thought (meant) about it.
Denne besaae den opmærksomt,
This (he) looked at (be-saw) it attentively (upmarksome),
forsikrende den var gód, pùttede den til
assuring (for-securing) it was good, put it to

sig, og forlangte
himself (Lat. *secum*, in his pocket), and demanded (for-
endnú 1 Shilling 8 Pence, da de engelske
longed) beside 1 shilling 8 pence, since the English
Love have fastsat en Taxt af 6 Shilling 8
law had fixed (fast-set) a tax of 6 shillings 8
Pence for et hos en Sagfører indhentet
pence for one of a lawyer received (into-handed)
Raad.
advice (Ger. *Rath*).

For a thorough study of this admirable language the following works may be consulted: Peder Syv, *Simbriske Sprog* (1663), the Cimbric being the basis of the Danish orthography; Erasmi Pontopidani *Grammatica Danica* (1668); Otho Sperling, *De Danicæ Linguæ Antiqua Gloria* (1694); J. Baden, *Roma Danica, sive Harmonia Linguæ Danicæ cum Latina* (1699); Iljösgaard made the system of 10 vowels, (1743); J. H. Schlegel on the advantages and defects of the Danish language (in Danish, 1763); Erasmus Rask's grammar for Englishmen (1830 and 1846). Dictionaries: H. van Alphelen, "Royal Dictionary" (in Danish, 1764–'72), and *Dictionnaire Français-Danois et Danois-Français* (1772–'6, 3 vols.); *Dansk Ordbog* (Danish Wordbook), under the direction of the society of sciences, by Möller, Viborg, Thorlachus, Müller, &c. (1793–1825, 5 vols.); Björn Halderson, lexicon, Icelandic, Latin, and Danish, edited by R. K. Rask (1814); Danish-English, by Ferral (1845–'54); Dansk ancient glossary, by Molbech (1853); history of the language, by Petersen (also Swedish), Molbech.—During the middle ages there appears to have been no Danish literature, and from the general Scandinavian literature, of which the ancient popular and heroic songs, or Vjämpeviser (collected for the first time by A. S. Vedel, 1591; latest edition by Rasmussen and Nyerup, 1821), are the most noteworthy remains. The codes of the ancient Danish kings, dating back to the 12th century, the "Book of Medicine," by Henrik Harpestreng, supposed to have been written in the 13th century (latest edition by Molbech, 1826); a "Chronicle in Rhyme," written in the latter part of the 15th century (ed. by Molbech, 1825); and Peder Lolle's collection of proverbs, probably dating from the earlier part of the 16th century (ed. by Nyerup, 1828), are the only extant relics of the Danish literature of the middle ages. The separation of Denmark from the united Scandinavian empire (1523), and the reformation (1527–1537), wrought as great a change in the literary as in the political development of the kingdom. The reformation introduced into Denmark not only German intellectual culture, but at the same time the classical study as opposed to the dry scholasticism of the middle ages. From that time the literature of Denmark began to emulate that of the other European nations. Christian Pedersen's first translations into Danish of the New Testament and the Psalms (1529), raised the Danish to a national language. Its musical softness as well as its clearness and perspicuity in the expression of abstract ideas favored its application to poetical effusions in preference to prose writing, and even now the prose writing of Denmark is hardly equal in value to its poetry. Thus, during the 16th and 17th centuries, the principal Danish works were poems, mostly of a religious character. Anders Arreboe (1587–1637) may be called the father of Danish poetry. Anders Bording (1619–1697), Thomas Kingo (1634–1723), the author of a number of excellent hymns, and Jörgen Sörterug (died 1722), who revived the old Scandinavian epic in a true national spirit, are the most prominent among the many writers of that time whose names are preserved in the history of Danish literature. A more popular kind of poetry was cultivated by Peder Dass (died 1708), Jens Sten Schested (died 1695), and Povel Inul (died 1723). Dramatic versions of biblical history were a favorite subject of the Danish poets. Of this class of productions, *Kong Salomons Hylding*, by Justesen Ranch (1585), *Samsons Fängsel* (1633), *Karrig Nidding* (1633), and *Susanna*, by Peder Hegelund (1578), were the most successful. As a humorous poet, Töger Reenberg (1656–1742) distinguished himself by his ready wit and sound moral sentiment. Researches into the earlier times of Scandinavian history were prosecuted with great eagerness by Danish scholars, and some of their historical writings are of great value even now, though they partake more of the character of chronicles than of modern philosophical historiography. Arild Hvitfeld's *Danmarks Riges Krönike* (1595–1604), Lyschander's *Danske Kongars Slägtebog* (1622), and Arent Berndtsen's *Danemarks og Norges frugtbare Herlighed* (1656), deserve to be mentioned. Northern archæology was cultivated by Gudmund Andreæ, Runolf and Arnin Johnson, Thomas Bartholin, Peder Rosen, Broder Bickerod, and Peder Syv. Still, the poetical and historical writings of that period of Danish literature were not sufficiently conspicuous to attract the attention of other nations. During the 17th century Denmark's fame in the republic of letters was principally established by such scholars as Tycho Brahe, the great astronomer (1546–1601), Kaspar Bartholin (1585–1630), Thomas Bartholin (1616–1680), the greatest anatomist of his time, Christian Longomontanus (died 1647), Ole Römer (1644–1710), Holger Rosenkranz (died 1642), &c. The classical period of Danish literature was inaugurated by Holberg (1684–1754), who, as a dramatic poet, a historian, a writer of fiction, and a popular philosopher, held a prominent place in the literary history of the last century. A strong, bracing realism pervades his productions. Most of his works have been translated into German, and the near affinity between the literature of the two countries having become evident, a close reciprocity ensued. Johannes Ewald (1743–1781), a lyrical poet and dramatist of great merit, holds a relation to Holberg similar to that of Schiller to Goethe; both their names stand as representatives of what has been termed the golden era of Danish literature. Next to them the following authors

of that period have justly obtained an extensive popularity: Joh. Herrmann Wessel (died 1785), Johann v. Wibe (died 1782), Frederik Wilh. Wiwet (died 1793), Joh. Clemend Tode (died 1806), Enevold Falsen (died 1808), and Christian Olufsen (died 1822), by their comedies, none of whom, however, rank with Peder Andreas Heiberg (1758–1841); Ole Johann Samsöe and Levin Christian Sander, by their excellent tragedies; Thomas Thaarup, by his vaudevilles; the brothers Friman and Joh. v. Brunn (died 1816), by their lyrical poems; Jens Zetlitz and the brothers Trojel, by humorous songs; Christian Pram by his romantic epic *Stärkodder* (1785); Wilh. Helf and Christian Falster (died 1752), by their satirical poems; Hans Adolf Brorson by his hymns; Johann Nordahl, by his patriotic songs; and Jens Baggesen, the favorite songster of the nation, by his lyrics and his comic epics. A new impulse was given to the national literature by Adam Oehlenschläger (1779–1850), who holds an equally conspicuous place in the literature of his own country and in that of Germany. Imbued with the spirit of the romantic school, he sought in the primitive history of his country for those popular traditions and reminiscences by which the individuality of national literature is defined and intensified. As an epic poet, Oehlenschläger holds a position among the greatest of modern times. Next to him stand Bernhard Severin Ingemann (born 1789), the author of the epics, *Waldemar de Store*, *Dronning Margrete*, and *Holger Danske*, and Fr. Paludan-Müller, whose *Adam Homo* (a composition which may with equal justice be classed among epic, didactic, or satiric poetry) is perhaps the most remarkable production of modern Danish literature. Among living lyrical poets, Chr. Winther, Hendrik Hertz, Chr. Hendersen, Chr. K. F. Molbech, and Rosenhoff, are the most eminent. As a composer of hymns, F. S. Grundtvig is unrivalled. The most fertile field of modern Danish literature is found in the drama and the novel. Johann Ludwig Heiberg (born 1791), a son of Peder Andreas Heiberg, a philosophical and archæological writer of great merit, is also the first among the living Danish dramatists; but he confines himself to comedy and vaudeville. The tragedies of Oehlenschläger have not yet been equalled by more modern poets. Most of the lyrical poets mentioned before are also authors of serious dramas or comedies, and some of them, as Hendrik Hertz and Ingemann, have obtained a well deserved reputation beyond the limits of their own country. P. Chievitz, Th. Overskou, C. Hostrup, F. H. Guldberg (died 1852), and Erik Bögh, deserve to be noted among modern Danish dramatists. The number of popular novelists is large. The first place among them seems to be conceded to Hans Christian Andersen, though the novels published anonymously by Heiberg are scarcely inferior to his. Sten Stensen Blicher, Ingemann, Kierkegaard, H. P. Holst, F. C. Sibbern, Torkel Trane, E. Lobedanz, and several others have published novels, some of which rise above the average of modern works of fiction. Great activity prevails in Denmark in the writing of history, national archæology, and philology. In metaphysics and æsthetics the modern Danish authors have, with few exceptions, followed the track of the Germans. F. C. Sibbern is perhaps the most independent thinker. In natural philosophy, Oersted has acquired a world-wide reputation. His most celebrated work, *Aanden i Naturen*, has been translated into all European languages. J. F. Schouw ranks highly among modern physicists and geographers. Eschricht, Paulsen, Sars, Steenstrup, are authors of valuable works on zoology; Schumacher, Hornemann, Dreier, M. Vahl, and Liebmann, have written meritorious works on botany; Forchhammer and Puggaard, on geognosy; Johann Madtvig and G. F. Boissen rank high among modern philologists; Peder Olaf Bröndsted (died 1842), Johann Ludwig, Ussing, and F. Chr. Petersen, among archæologists. To Rask, Westergaard, and Fausböll, linguists are indebted for valuable researches. Among those scholars who have devoted themselves particularly to the study of Danish literature and literary history, Nyerup, Petersen, Rask, P. E. Müller, and Molbech are the most prominent. Of the remains of the ancient Scandinavian and Danish literature, numerous critical editions have been published by Halfdan Einersen, Johann Erichsen, Olaf Olavius, Hans Finsen, Finn Johnsen, Björn Haldersen, Steph. Björnsen, John Olavsen, Skule Thorlacius, G. J. Thorkelin. The number of Danish historians within the 2 last centuries has been very great. Erik Pontoppidan (died 1764) stands at the head of those of the 18th century, while Grundtvig has attained to the highest reputation among those of the present day.—See Nyerup's *Almindelig Moerskabsläsning i Danmark og Norge* (1816); Molbech's *Forelæsninger over den nyere Danske Poesie* (1831–'32); Thortsen, *Hist. Udsigt over den Danske Litteratur* (1839); Th. H. Erslew, *Almindeligt Forfatter-Lexicon for Danmark* (1843–'53, 3 vols.; suppl. vol., 1856–'58).

DENNER, Balthasar, a German portrait painter, born in Altona or Hamburg in 1685, died in the latter place, April 14, 1747, or according to another account at Rostock, in 1749. He was employed by Frederic II. and many other German princes, and was also invited by George I. to England, where, however, he met with little encouragement. His chief, if not his whole merit, consists in the mechanical finish of his pictures, some of which, it is said, require to be examined by a magnifying glass in order to appreciate the labors of the artist. There is a head of an old woman by him in the gallery of Vienna, in which even the down on the cheeks and the pores of the skin are represented with scrupulous exactness. This picture was purchased by the emperor Charles VI. for 4,700 imperial florins, and the artist was commissioned to furnish a companion piece of an old man, which is not less carefully finished.

DENNIE, Joseph, an American author and journalist, born in Boston, Mass., Aug. 30, 1768, died in Philadelphia, Penn., Jan. 7, 1812. After a brief experience of mercantile life, he entered Harvard college, where, notwithstanding his vivacious temperament on several occasions brought him into collision with the authorities, he was graduated in 1790. In the same year he commenced the study of law in Charlestown, N. H., and was subsequently admitted to the bar, at which, however, his practice was very inconsiderable. During several months in 1793 he read the Protestant Episcopal church service on Sundays to some members of that denomination in Claremont, and showed such excellent powers of elocution that he was solicited to enter holy orders, with the promise of a settlement in Portsmouth. In 1795, having previously acquired some reputation by literary contributions to various newspapers, under the title of the "Farrago," which had been very generally copied, he became connected with a small weekly journal published in Boston, called the "Tablet." This publication survived its establishment but 3 months, and in the summer of 1795 Dennie removed to Walpole, N. H., and accepted a permanent engagement on the "Farmer's Weekly Museum," a newspaper which enjoyed an extensive popularity toward the close of the last century. His most notable contributions to this were a series of essays, entitled the "Lay Preacher," in which, to use his own language, he sought to "unite the familiarity of Franklin with the simplicity of Sterne." The articles were discursive and lively, were widely copied by the newspapers of the Union, and procured for their author an established position among the few literary men whom the country then possessed. Shortly afterward Dennie assumed the editorship of the "Museum," and by collecting around him a number of able contributors so increased its reputation and circulation, that in the latter part of 1797 the publisher announced with some exultation that the journal was read by upward of 2,000 persons, and had its patrons in Europe and on the banks of the Ohio. In 1798 the bankruptcy of the publisher irretrievably ruined the prospects of the "Farmer's Museum," and Dennie was soon after induced by his friends to become a candidate for congress from New Hampshire. Having been defeated, he left Walpole in 1799 for Philadelphia, to fill the position of confidential secretary to the department of state, over which Timothy Pickering then presided. He remained in office but a few months, and in the latter part of 1800, in connection with Asbury Dickins, commenced the publication in Philadelphia of the "Portfolio," in which he adopted the editorial cognomen of "Oliver Oldschool." At the outset a quarto weekly, it subsequently became a monthly publication. Apart from the contributions of the editor, it was the vehicle of frequent communications from John Quincy Adams, whose letters from Silesia were originally published in it, Horace Binney, Judge Hopkinson, Robert Walsh, Charles Brockden Brown, and other literary men of the time, and maintained for many years a considerable reputation. In 1803 Dennie was indicted for a libel against the federal government, published in his journal, but was acquitted. He continued to be connected with the "Portfolio" until his death, and was highly esteemed for his social qualities as well as for his literary abilities.

DENNIS, a post village and township of Barnstable co., Mass., on the peninsula of Cape Cod. The township extends entirely across the peninsula, here 8 m. wide, and is separated from Yarmouth by Bass river. It contains 6 churches, a bank, and some ship yards. Most of the inhabitants are engaged in commerce and the fisheries. About 250 vessels, with an aggregate burden of 35,000 tons, are employed in the coast trade; 10 or 12 ships are engaged in the freighting business, and in 1853 there were 48 vessels (aggregate tonnage 3,160) in the mackerel fisheries. The first settlement was made at Dennis village, in the northwestern part of the township. Pop. in 1855, 3,497. Value of property in 1854 estimated at over $1,000,000.

DENNIS, John, an English critic, born in London in 1657, died Jan. 6, 1733. He was the son of a tradesman, but received a liberal education, and took the degree of A.M. at Cambridge in 1683. Afterward he travelled on the continent, and returned with a strong dislike to the forms of government existing there. He became a whig in politics, and mingled much in the society of the politicians of that school, and of the literary men of London. Among his friends were Dryden, Halifax, Wycherley, and Congreve. By his expensive habits he soon dissipated a small fortune which had been left him by an uncle, and the duke of Marlborough, hearing of his difficulties, obtained for him an appointment in the customs worth £120 a year; but he was compelled, after a while, to sell this to satisfy pressing demands, only reserving from the sale, at the suggestion of Lord Halifax, a small pension for himself for a term of years. This term he however outlived, and was in consequence reduced to great poverty, and becoming blind, was compelled in the latter part of his life to depend upon the charities of literary friends, many of whom he had grossly calumniated. As a dramatist he hardly deserves mention, though some of his plays obtained a transient popularity, especially the one entitled "Liberty Asserted," in which the French, with whom the English were then at war, were roughly handled. Of his essays the best are the "Grounds of Criticism," and those on Addison's "Cato," and Pope's "Rape of the Lock," though the 2 latter are characterized by the bitterness with which he usually spoke of his contemporaries. Addison had been one of his friends, but he took offence at something which appeared in the 2d and 3d numbers of the "Spectator," and which he supposed to refer to himself, and, in revenge, wrote the essay on "Cato." He was a man of a very peevish and suspicious disposition, and was al-

most always engaged in controversy. He attacked Pope, Addison, and Steele; and Pope in return satirized him in several works, especially in the "Dunciad." He had also a most exaggerated idea of his own importance. While the negotiations were in progress previous to the peace of Utrecht, he was in great fear that the French king would refuse to make peace except on condition that the author of "Liberty Asserted" should be delivered over to him. One day, being at the house of a friend on the Sussex coast, and perceiving a vessel in the distance, he was seized with the idea that it was coming to carry him away to France, and that he had been inveigled thither for that purpose. Accordingly he immediately set out for London, congratulating himself on his escape. He had invented a new way of imitating thunder for his play of "Appius and Virginia," which was brought out and failed in 1708; shortly afterward, during the performance of "Macbeth," hearing the thunder produced by his apparatus, he rose in the pit, and exclaimed: "S'death! how these rascals use me; they will not let my play run, yet they steal my thunder."

DENOMINATOR, in algebra and arithmetic, the divisor used in producing a fraction. The denominator of a decimal fraction is not written; it is equal to 1, with as many ciphers annexed as there are places in the fraction. The name denominator is derived from its arithmetical use, since it gives the denomination or name to the fraction, 3ds, 5ths, 7ths, &c., while the numerator gives the number of parts taken.

DENON, Dominique Vivant, baron, a French archæologist, born at Châlons-sur-Saone, Jan. 4, 1747, died in Paris, April 27, 1825. He accompanied Bonaparte to Africa as a member of the Egyptian commission. His *Voyage dans la basse et la haute Égypte*, which excited much interest on its publication in 1802, was a forerunner of the magnificent work afterward published by the Egyptian commission.

DENSITY, a term somewhat indefinite in meaning, being sometimes used in its true sense, and referring to the number of particles of matter comprised in a given space; sometimes in a secondary sense, as synonymous with specific gravity. In the first sense it is opposed to rarity, and the density of one substance cannot properly be compared with that of another, there being no mode of measuring the absolute size of particles of matter, or their absolute weight. All bodies are believed to be to some extent compressible, and gases are compressible in exact proportion to the force used in compressing them; at least, this is the result obtained by experiment; but it may not be the exact law, and probably does not hold true when the gas is nearly compressed into a liquid, or when the pressure is almost nothing.

DENT, a S. central co. of Mo., recently formed out of the N. part of Shannon co., and named in honor of Frederic Dent, an early settler in Missouri. The soil is fertile, and the surface is much diversified. Pop. in 1856, 3,207, of whom 118 were slaves.

DENT, John H., a captain in the U. S. navy, a native of Maryland, died in July, 1823. He commenced his career as midshipman in March, 1798, under the command of Com. Thomas Truxton, in the frigate Constellation of 36 guns, and was attached to that ship when she captured the French frigate Insurgente, on Feb. 1, 1799. Soon after the engagement he was promoted, and served in the same ship as 4th lieutenant when she captured the French frigate La Vengeance, on Feb. 1, 1800. He served in command of the schooners Nautilus and Scourge, in the squadron of Com. Edward Preble, during the war with Tripoli, and participated in the several attacks upon that city and harbor in the months of July, August, and September, 1804. He was promoted to the rank of master commandant in Sept. 1804, and to that of captain in Dec. 1811.

DENTATUS, Marcus Curius, a Roman consul, who flourished in the 1st half of the 3d century B. C. He was of Sabine origin, and the first of his family that ever filled any high public office. In 290 B. C. he subjected the Samnites; in 275 he vanquished Pyrrhus in two great battles; in 274 he subdued the Samnites, Lucanians, and Bruttians. On the conclusion of his 3d consulship he retired to a small farm in the country of the Sabines, and cultivated it with his own hands. While thus engaged the Samnites sent an embassay to him with costly presents. They found him sitting at the hearth cooking vegetables for his dinner. He rejected their gifts, telling them that he would rather rule over those who possessed wealth than possess it himself. In 272 B. C. he was called to fill the office of censor, in which capacity he constructed an aqueduct which conveyed water from the Anio into the city, and by a canal he carried off the water of the lake Velinus to the Nar, and thus gave to the Reateans a large tract of excellent land. He is said to have been born with teeth; hence his surname of Dentatus.

DENTISTRY, Dental Surgery (Lat. *dens*, tooth), the surgical treatment of the teeth, including, beside their extraction, the remedying of their serious defects, and the mechanical operation of making and fitting artificial teeth to supply the places of those lost. Although it is only within less than a century that this art has taken the rank of a distinct profession, attention was directed from the earliest periods to the means of preserving and improving the beauty of the teeth. The ancient Hebrew writers evidently appreciated their importance in giving expression to the countenance, as when Jacob blessing Judah says: "His teeth shall be white with milk" (Gen. xlix. 12); and Solomon compares a fine set of teeth to a flock of sheep even shorn (Song of Solomon, iv. 2). In the time of Herodotus the art of dentistry appears to have been practised in Egypt as a distinct branch of surgery, as was also the treatment of the diseases of the eye and of the ear. Little, however, is known of the attainments of these early practitioners. In the ancient tombs

of this people artificial teeth of ivory or wood were found by Belzoni and others, some of which were fastened upon gold plates. It is also stated that teeth of the mummies have been found filled with gold. Thus it would seem that the ancient Egyptians understood processes of the art which are commonly regarded only as inventions of the refined nations of modern times. Artificial teeth are alluded to by several of the Greek and Latin poets, as Ovid, Martial, Horace, &c. The works of Galen, written in the 2d century, contain the earliest treatises upon this subject, and they continued to be the best until the works of Fallopius, Eustachius, and Ambrose Paré appeared in the 14th, 15th, and 16th centuries. During the 18th century the attention of medical men in France and England was directed to the subject, and a number of elaborate works were published devoted exclusively to the art. These, and prominently among them the treatise of John Hunter (1771–'78), laid the foundation of the English school of dentistry. The subject, however, was treated anatomically and philosophically rather than practically; and the same may be said of the writings of the eminent French surgeon of this period, Bichat. Neither of these was a practical dentist, and the subsequent publications of Dr. Blake in 1798, and of Fox in 1803 and 1806, as of others at later dates, served rather to elucidate the physiology of the teeth and the nature of the diseases to which they are subject than the method of treating them. From advertisements in the newspapers of 1703 the practice of the art, making teeth and cleaning them, appears to have been in the hands of silversmiths or jewellers. In 1826 the eminently practical work, "Principles of Dental Surgery," of Leonard Koecker, M.D., who had practised dentistry from 1807 to 1822 in Baltimore and Philadelphia, appeared in London, and fully established the claims of the art to take rank as a distinct branch of science. From that time new treatises by able writers and practitioners have continued frequently to appear. The progress of the French school was very rapid in the early part of the present century. Prof. Baume's treatise on first dentition and the diseases that accompany it appeared in the year 1800; and 2 years afterward, a work on the theory and practice of the art, by Laforgue. The former has been translated into English, and incorporated into the "American Journal of Dental Science." The works of Duval, interesting for their historical research as well as their practical instruction, have been much read. Leroy's work on diseases of the gums (1806) has been translated and published in the "American Journal." A number of works were published by Delabarre between the years 1815 and 1826 on different subjects relating to the teeth and their treatment. Among them is a treatise on "Mechanical Dentistry," published in 1820, and illustrated with 42 plates. It was during this period, when publications upon dentistry were frequently appearing in France, that the manufacture of artificial teeth of porcelain was introduced; and in 1821 a work upon this subject was published by Audibran of nearly 200 pages, entitled *Essai historique et pratique sur les dents artificielles incorruptibles.* By this it appears that Fauchard in 1728 proposed their manufacture; and that in 1776 Duchateau, a chemist of St. Germain-en-Laye, attempted to produce them, and finally succeeded with the aid of Dubois, a dentist of note in Paris. The latter imitated the colors of the natural teeth and gums by the use of mineral oxides, and obtained royal letters patent from Louis XVI. for the invention. The progress of this branch of the art will be particularly noticed in the latter part of this article.—The practice of dentistry was introduced into the United States by Le Mair, of the French forces which joined our army during the revolutionary war. An Englishman named Whitlock also commenced the practice soon after the arrival of Le Mair. About the year 1788 Mr. John Greenwood established himself in New York, the first American of this profession. In 1790, and again in 1795, he carved in ivory an entire set of teeth for Gen. Washington. They were secured by spiral springs, and the neatness and ingenuity of the work was considered equal to any executed at that period abroad. Other dentists soon appeared in New York, Philadelphia, and Baltimore. Their work included the extracting of teeth, filing and cleaning them, and replacing the natural teeth when lost with artificial ones, commonly made of ivory. Dr. Hudson, formerly of Dublin, who had settled in Philadelphia, first directed his attention particularly to the cure of the diseases of the teeth, and to arresting the progress of dental caries. In 1820 the number of practitioners in the United States was probably little more than 100. Ten years afterward, as estimated by Dr. C. A. Harris, in his work on the "Principles and Practice of Dental Surgery," there were about 300, of whom probably not more than $\frac{1}{6}$ were well instructed. But the increase in their numbers was afterward very raipd. In 1842 they were believed to number about 1,400, and in 1858 about 4,000. An important event in the history of dental surgery in this country was the establishment of the "American Journal and Library of Dental Science" in Baltimore, in 1839. The society of dental surgeons was soon after formed, and at its second annual meeting the "Journal" was made the property and organ of the association. Maryland, which appears to have taken the lead of the other states in this department of science, founded by its legislature, a few months previous to the organization of the society above named, a college of dental surgery, with 4 professorships, designed for instruction in the principles and mechanical practice of the art. Two years afterward another society of dentists, like that of Baltimore, was organized at Richmond, Va., and in Aug. 1844, a third was formed at Cincinnati, Ohio, styled the "Mississippi Valley Association of Dental Surgeons." A college of

dentistry has also been established in Philadelphia and another in Cincinnati, and state and local dental societies in various parts of the country. In Aug. 1855, the national convention of dentists was organized, through the active exertions of Dr. Elisha Townsend of Philadelphia, and its first annual meeting was held in that city. Dr. John B. Rich of New York was its first president. Beside the reports of these societies, which have disseminated a knowledge of the discoveries and improvements made in the science, many very valuable works of a practical nature have been published by American authors, among which may be noticed a treatise by J. Gardette of Philadelphia, originally of Paris. This was published in 1821. In 1822 appeared in New York and London an essay on the "Disorders and Treatment of the Teeth," by Dr. E. Parmly; also, the same year, 2 volumes by Dr. L. S. Parmly, and a work called the "Family Dentist," by J. F. Flagg, M.D., of Boston. In 1829 a comprehensive treatise, and probably the most valuable ever published to that time, appeared, in one volume of over 500 pages, written by S. S. Fitch, M.D.; in 1835 a second and improved edition was published. A poetical essay, entitled *Dentologia*, by Dr. Solyman Brown, with notes by Dr. E. Parmly, is a curious and ingenious production, which appeared in 1833. The same author also published other works and many valuable papers on dentistry. The "Guide to Sound Teeth," by S. Spooner, M.D., is a valuable work, printed in 1836. The "Principles and Practice of Dental Surgery," by Prof. C. A. Harris, of the Baltimore college, is a standard text book of 600 pages 8vo.; the second edition was published in 1845. Dr. Harris also published a large 8vo. dictionary of dental surgery. In 1854 a comprehensive 8vo. volume was published by A. Snowden Piggot, M.D., entitled "Chemistry and Metallurgy as applied to the Study and Practice of Dental Surgery." A number of periodicals are supported by the profession, as the "Dental Register of the West," a quarterly, published in Cincinnati; "Dental Review," St. Louis, quarterly; "Dental News Letter," Philadelphia; the "Obturator," New Orleans, &c.—From this sketch of the history and progress of the science, it is apparent how highly its cultivation is appreciated among civilized nations. Ruder people also show a regard for the teeth, which is oftener displayed, however, in attempts to ornament them by coloring and giving to them grotesque shapes, than by devising means to preserve them. This last, indeed, is little required with people living the inartificial life of savages, and subsisting upon the simple food they use. Their teeth partake of the perfect development of their physical constitution, and are generally sound, healthy, and beautifully white. The natives of Hindostan, and the high caste Brahmins especially, are said to devote particular care to the preservation of these organs. With them it is a religious duty, inculcated in their most ancient books, to pay scrupulous regard to their cleanliness. Every morning they spend an hour rubbing them with a twig, while performing at the same time their devotional exercises. The result is that they have the finest teeth of any people.—The progress of dentistry as a science has been necessarily consequent upon that of anatomy. As the physiology of the system was better understood, the relations of the various organs to each other, and their mutual dependence, were more clearly perceived. Dentistry ceased to be a merely mechanical art, when the treatment of the teeth demanded a comprehension of these relations, and when he who practised it paused before operating, to consider whether the pain he hoped to remove with instruments might not better be alleviated by proper medical treatment, by the application of leeches to the gums, or, when it was of the nature of neuralgia, by the surgical operation of dividing the affected nerve. So intimately connected is the welfare of the teeth with that of the general system, that some knowledge of medicine, and of the diseases whose effects may reach these organs, is indispensable to the scientific dentist. His knowledge of anatomy is not confined to the bony structure of the tooth, to the soft pulp which fills its internal cavity, to the position of the nerves which communicate its complaints to the brain, nor to the manner in which it is held so fast in its socket. His science involves an acquaintance with the anatomical relations of the organs of the mouth with all parts of the system. The mucous membrane that lines it extends to the stomach and other internal organs, as the liver, intestinal canal, and those of respiration, through the larynx, trachea, and bronchi. An unhealthy condition in one part of this membrane is manifested in another. Canker, the cause of which is in the stomach, appears as a disease of the gums or the tongue. When this member is furred or coated with an unhealthy secretion, it is an indication of disease in the intestines or other internal organs. The teeth may be injuriously affected by this unhealthy secretion, the remedy for which is to be applied to other organs. The nerves, spread like a network throughout the whole system, are affected frequently in the teeth by the diseases of distant members; and an operator unskilled in their affections often sacrifices sound teeth without benefiting the sufferer by their removal. Dr. Harris mentions an instance of a gentleman, who, afflicted by such an affection of the nerves, had all the teeth on the right side of both jaws thus uselessly removed. Mr. Fox, the anatomist and physiologist, as well as dentist, being applied to in a similar case, suspected the real nature of the disease, and taking the patient to Sir Astley Cooper, a radical cure was effected by the operation of dividing the affected nerve. The effects of this connection through the nerves are reciprocal, and other members suffer in consequence of diseased teeth. Baglivi noticed this in his *Canones Medicinæ*, published in 1710: "Persons whose teeth are in an unclean and

viscid state, though daily washed, have uniformly a weak stomach, bad digestion, an offensive breath, headache after meals, generally bad health, and low spirits." Physicians, when consulted in chronic and nervous affections, often now examine the teeth, and refer the patient to the dentist. Many cases of that terrible disease, *neuralgia faciei*, which have resisted all other treatment, have been cured by the removal of diseased teeth. The nerves belonging to the eye, ear, nose, mouth, and which pass over the cheek and are distributed in many branches through the teeth, are ramifications of the great nerve of sensation, the 5th of the anatomist. Whatever part of this chain be irritated, the pain may be experienced in any other part. Thus, stumps of teeth, lying apparently harmless, may be the cause of terrible neuralgic pains in the head, as well as, for the other reason above given, of a number of other diseases apparently originating from the stomach, or often attributed in common language to impure condition of the blood.—The means of preventing the diseases to which the teeth are subject, is a branch of dental science quite as important as that relating to the arrest and cure of these diseases. These means consist, first, in giving what assistance nature requires to bring the teeth of second dentition into a regular arrangement; and secondly, in the care of the individual himself in preserving the teeth uniformly clean. As the temporary or first set of teeth drop out, which as a general rule they should be allowed to do, by their roots being absorbed, the second set already formed succeed and take their places. Of the temporary teeth there are but 20, and these are of small size. The teeth of the second dentition are 32 in number, with one or two exceptions are of larger size than their predecessors, and consequently occupy a greater space. Yet these, appearing one by one, take their places, and should occupy in the harmonious process of the growth of all the parts the same room apparently that was filled by the 20 deciduous teeth. This is accomplished by the elongation forward of the jaw, and the arch gradually assuming the form of a semi-ellipse in place of that of a semi-circle. But if any of the first teeth have been indiscreetly removed before their time, or as indiscreetly allowed to remain so as to interfere with the growth of the permanent teeth, an inequality of resistance is offered to the progress of some of the second set, which is apt to cause an irregularity in their arrangement. The same effect is often produced without any apparent cause other than that the increase of the teeth and that of the jaw do not proceed *pari passu*. A tendency to this is often noticed to be hereditary. Teeth irregularly arranged, interfering with each other, or as they sometimes do with the lips, or pointing inward so as to be removed from the healthy action of mastication, or twisted in their sockets, are not only disfiguring, but are particularly liable to disease and decay. From their first appearance to the age of 16 of the individual, they may be treated by various mechanical applications attached to the other teeth and bearing suitably upon those to be brought into place, so that without violence the work of nature is gently assisted, and a perfect set is gradually formed. So essential is this to the future welfare of the teeth, that by due attention of this kind, in the opinion of an eminent dentist, "there would not be one decayed tooth where now there are a dozen." (Harris, p. 134, 2d ed.) Cleanliness is the second requisite for sound teeth. The principal cause of their decay is generally admitted to be the presence of decomposing particles of food lodged between them. All dentists strongly urge the importance of children early acquiring the habit of brushing the teeth twice daily. Dr. L. S. Parmly goes so far as to say: "Where the teeth are kept literally clean, no disease will ever be perceptible. Their structure will equally stand the summer's heat and winter's cold, the changes of climate, the variation of diet, and even the diseases to which the other parts of the body may be subject from constitutional causes." By neglect of this duty the teeth are likely to be soon affected with caries. This disease may go on insidiously and unsuspected, involving not merely the risk of loss of these organs, but, unless exposed by the intense pain, which by a wise and beneficial provision it commonly involves, affecting the general health of the individual, and inducing maladies of the most alarming character. Many cases of disease thus engendered it is too often the province of the dentist to treat, and the life of the patient is not always saved even by the sacrifice of all the teeth. Caries of the teeth is also induced by vitiated secretions of the mouth arising from severe constitutional disorders, or the continued administration of different kinds of medicine; or it is sometimes due to a predisposition inherited from one or both parents. Its treatment is to remove the affected part, when this is superficial, by the use of the file. The surface of the bone from which the enamel is removed must be left smooth and polished, and if proper care be afterward taken in keeping it clean, the disease may not return. If the decay has extended into the bony substance of the tooth, the filing is then only preparatory to the complete removal of the diseased portion by excavating with suitable instruments, and filling the cavity with some proper material. Much attention was formerly given to shaping the cavity, in order that by its contracted aperture the filling should be held in as by dovetailing; but by the use of gold foil and sponge gold specially prepared for this purpose, it is now found practicable to apply the metal in successive portions, and build up a solid block of any shape by incorporating each portion with that which preceded it. This is done by a sort of stippling with suitable instruments, and the gold may be thus rendered so compact, it is affirmed, that its specific gravity shall

equal that of the cast metal. In wide-mouthed cavities the filling is secured by being built upon plugging carefully introduced into the cavities of the roots, and also by lateral pins of the gold filling made to enter from this into little holes or grooves drilled for the purpose into the walls of the tooth. In order to destroy the sensitiveness of the exposed nerve, Dr. Spooner of Montreal first recommended the use of arsenic, and this was made public in a treatise of his brother, Dr. S. Spooner of New York. For killing the nerve and for deadening the sensitiveness of the bone of the tooth, when but a thin shell of this covers the nerve, it is now used in combination with sulphate of morphine and tannin, in the proportion of 3 parts of each of the last two named to 1 part of arsenic. A portion of a grain weight of the mixture is introduced into the cavity, and allowed to remain long enough to accomplish the object. It has been generally considered impracticable to preserve a tooth when the decay has reached into the internal or pulp cavity. In this condition inflammation often takes place at the root, and matter collects, forming an ulcer between the periosteum of the tooth and the bone. If the discharge of this be stopped by filling the cavity, the matter will find its way through the gum, causing a gum boil near the root; or it produces inflammation of the face, often attended with great suffering, which is relieved only by the removal of the tooth. The modern treatment is to perforate the sac at the root by a fine drill passed through the cavity; and if the nerve be sensitive, this is cut out and removed by a delicate steel wire furnished with a hook at the end, so small that it can pass freely into the nerve cavity. A weak solution of nitrate of silver is then forcibly injected into the cavity, the curved beak of the syringe being surrounded with wax, which is crowded into the tooth to prevent the escape of the caustic solution. This is immediately washed out, and a piece of the solid caustic is introduced into the lanced gum boil, which connects with the diseased fang. The unhealthy portions are thus cauterized, and after creosote introduced into the cavity has remained a few days, and healthy action has taken place, the tooth may be safely filled, with the liability of further trouble from the same cause greatly reduced. —The only unobjectionable material for filling teeth is gold foil or the sponge gold specially prepared for this purpose. The latter excellent material is produced by dissolving gold free from copper in nitro-hydrochloric acid, placing the solution in a flat-bottomed vessel, and heating and precipitating by strong solution of oxalic acid. In a few hours the gold is wholly deposited, and the supernatant liquid may be decanted off, taking care not to disturb the gold at the bottom. The vessel is then several times filled with boiling water and decanted, until the last washings contain no more oxalic acid. The gold is now carefully slipped on to a piece of filtering paper, and by means of a spatula gently pressed into the form of the desired cake, but a little thicker. It is then removed to a porcelain crucible, and heated for a short time, somewhat below a red heat, when it shrinks and becomes coherent. This process was described to the London chemical society by Mr. D. Forbes in 1857. Tin foil may be used, and its malleability and cheapness well adapt it for large and badly shaped cavities, and for temporary fillings in sensitive teeth, but it is liable to oxidize and produce discoloration. The mineral cement, or amalgam of mercury, silver, and tin, has been found by some dentists a very convenient material for inserting in its soft, fresh state into cavities, particularly when these are large, badly shaped, and the tooth very sensitive. It very soon sets, forming an imperishable and exceedingly hard filling. Many dentists approve of its occasional use, provided it is composed of chemically pure materials. Others loudly condemn it, asserting that it is liable to occasion salivation, inflammation of the periosteum, and of the gums and mucous membrane.—The extraction of the teeth is an important branch of dental practice—safe and easy with good instruments in skilful hands, but, as practised by the unprofessional operator, not a little hazardous. This is apparent from the cases recorded of the extraction in one instance of 6, and in another 5 teeth at once, together with the tearing away of the anterior and posterior plates of the cavity called the antrum in the roof of the mouth, which occurred in one case in Virginia, and in the other in North Carolina, a blacksmith being the operator in each case. Ambroise Paré particularly notices the danger of inexpert operators attempting to extract teeth. Speaking of his "tooth mullets," he observes: "Unless the person knows readily and cunningly how to use them, he can scarcely so carry himself but that he will force out 3 teeth at once." The improved instruments of modern times, however, have greatly lessened this risk, and pain is avoided by the use of anæsthetic agents, if necessary, or by the application of the galvanic current. In this process, which is a late American discovery, the current from the common electro-magnetic machine used for medical purposes is caused to pass through a wire, one end of which is held in the hand of the patient, and the other is attached to the instrument. This end, however, is broken, and is closed only when the operator has fixed the instrument and is ready to draw the tooth. He then presses with his foot upon a board which closes the circuit, causing a slight shock to pass through the jaw. Unless the gum is inflamed and sore, the effect is almost always to benumb the nerves, so that the tooth is removed with little or no pain.—The last department of dentistry to be noticed, is the construction and application of artificial teeth. These were formerly carved from ivory of the tusk of the elephant or the tooth of the hippopotamus. They were obtained also by altering the shape of the teeth of neat cattle, of sheep, &c.; and the crowns of human teeth were often conveniently ingrafted upon the roots

of the original front teeth. All these materials are objectionable from their susceptibility to the action of the fluids of the mouth; ivory soon becomes offensive from being saturated with these fluids, and all of them are liable to decay, inducing at the same time disease in the sound teeth remaining. Porcelain teeth, well named incorruptible, perfectly resist the corrosive action of the fluids of the mouth; and as they are now manufactured, they imitate so perfectly in color and animated appearance the natural teeth, that they are often not easily distinguished from them, unless their superior beauty excite suspicion of their true character. Though of French invention, they owe their present perfection in great part to the skill of American dentists. But their manufacture being a distinct art from that which properly pertains to dentistry, and requiring peculiar skill and experience, it is now mostly carried on by persons not belonging to the profession. Single teeth are thus prepared of all the varieties that may be required, and sold to the dentists at very low prices. The first experiments in this branch in the United States appear to have been made by Mr. Charles W. Peale of Philadelphia, who, compelled at an early age to use artificial teeth of ivory, and seeing in the newspapers about 1807 an account of mineral teeth, procured pure qualities of clay and silex, and, constructing his own furnace and muffles, moulded the artificial teeth and gums in wax, made casts in plaster and brass, and swaging the gold plates, fitted them with platinum wire and gold springs of his own manufacture, and produced sets for himself and some of his friends. He made a set for his son, Rembrandt Peale, in 1808, and gave instructions in his methods to Mr. Barabino, a dentist then practising in Philadelphia. The first regular manufacturers were Greenwood, Woffendale, and Parkhurst, who were engaged in the business about 1825. French artificial teeth were made in Philadelphia from 1827 to 1830, by Plantau and McHenry. In 1829 Mr. Villers came to New York from England, bringing with him mineral teeth, which he claimed to have made by a process he discovered in 1819. The proportions of the ingredients he used in 1830 are similar to those employed at present, viz.: 4 ounces of feldspar, 1 of crystallized quartz, and 12 grains of kaolin. The manufacture of mineral teeth for the supply of dentists was first undertaken by Mr. Daniel W. Stockton, in Philadelphia, about the year 1835; and to him, together with Neal and Alcock, is due the credit of establishing this branch of business in the United States. Other persons followed their example, until in the different cities of the United States there are no less than 9 manufactories devoted to this business, the aggregate annual production of which is over 2,000,000 teeth. The consumption of platinum for the little pins which fasten these upon the plates is estimated at about $40,000 worth annually. They produce both single teeth and teeth in blocks of several.—Various methods of securing artificial teeth in their places have been in use. So long ago as 400 years before the Christian era, they were fastened by ligatures of flax and of silk, and with wire of gold and of silver, to the natural teeth that remained. The insertion of pivots of gold into the roots of the natural teeth for attaching to these artificial crowns was long since practised, and platinum and hickory wood have been substituted for gold. In modern times metallic clasps, spiral springs, and fastenings of gutta percha and of caoutchouc, have been used for this purpose; and a dentist of London has lately contrived a covering of vulcanized caoutchouc to slip over the wires, to protect the natural teeth from their wearing action. But the most perfect method is to secure the teeth, either in whole or partial sets, to a plate of gold or other metal, which is so accurately fitted to the gums that it is firmly retained by atmospheric pressure. Plate-work involves several distinct operations. The first object is to obtain, in some hard metal, an exact model of the mouth in which the plate is to be fitted. For this purpose, yellow or white wax, free from mixture of grease, and softened by warm water, is placed in a shallow vessel, called an impression cup, which may be introduced into the mouth. Plaster of Paris made into paste may be substituted for the wax. The contents of the cup are firmly pressed around the gums, and, if for the upper jaw, are made to cover the roof of the mouth as well. With care, an experienced operator thus obtains in a few minutes an exact mould of the parts to which the material is applied. The teeth, if any are present, leave their forms faithfully impressed in their true positions, and the cavities between are represented by corresponding projections in the wax or hardened plaster. The impression removed from the mouth serves to furnish a model of the jaw, which may be taken in plaster of Paris also. This is used as a pattern in moulding sand, and a cast is then obtained in any metal, as, for instance, zinc; and by pouring melted lead upon the zinc, which is turned over upon its face and surrounded with a brass or iron collar for retaining the lead, a mould in this metal is obtained precisely like the original one in wax; or the same may perhaps be more surely secured by pressing the cast into the surface of melted lead, and holding it till the lead cools. By means of the zinc cast and lead mould, the exact shape of the parts is transferred to the sheet of gold or other metal, this being placed between the two, and made, by hammering and swaging, to assume all their irregularities of surface. The fit is the more readily made, if, from the plaster model, the teeth have been cut off before making the metallic casts. A duplicate plaster cast serves to give the position of those teeth to which the plate is to be finally fitted. The edges of the plate are cut to fit between the teeth, and where there are none, they bend over the rounded gum with its exact curve. The metal commonly used for the plate is gold, more or less alloyed; for cheap sets silver is sometimes

substituted. When it has received its proper shape, a ridge of wax is laid around the lingual side, and it is placed in the mouth, in order that the patient, by opening and shutting the jaws, may indent the impressions of the teeth in the opposite jaw, which will indicate the arrangement and length of the artificial ones to be attached to the plate. The plate with the wax is then taken out of the mouth, and brushed over with sweet oil. It is then laid upon its face, and plaster is poured over it, imbedding in it a wire frame, which is bent around somewhat in the form of the jaw, and projects behind the plaster. When the plaster is hardened, another portion is poured over the other side, and in this a similar wire is introduced. The oil prevents adherence of the plaster to the plate and wax. The two frames being hinged together, and set at the right distance apart, represent the two jaws; they are called the articulator, and are used for temporarily holding the artificial teeth, while they are selected and placed in their correct positions, with reference particularly to their articulating properly with those in the opposite jaw. A little wax laid upon the alveolar ridge of the plaster model causes the teeth to adhere as they are pressed back upon it. In the same way they are held when transferred to the plate, upon which the ridge of wax lies behind them. To secure them and admit of the removal of the wax, the front portion of the plate is imbedded in a mixture of plaster of Paris and either sand or asbestus, which mixture entirely covers the fronts of the teeth. The wax can then be taken away, and the backs of the teeth be exposed without displacing them. The next step is to fasten these by a lining of the same metal as the plate attached to each tooth by the little pin in its back, and to the plate by soldering. This being securely done, the plate and teeth thoroughly cleansed, and the metal polished, it is ready for the mouth. —The numerous joints and open spaces, which were liable to catch and retain particles of food, formerly rendered this work very imperfect. The improvements which have brought it to its present state of perfection are due to the skill of American dentists. A variety of materials have been experimented upon, in which to securely imbed the bases of the teeth. Gutta percha has been used to contain them; but its texture and strength were in a short time destroyed by the action of the fluids of the mouth. It was then applied vulcanized or mixed with sulphur; and caoutchouc is employed in the same way. These prove to be important auxiliaries in mechanical dentistry, especially for temporary sets of teeth. They do not, however, readily take the colors which may be applied to more suitable substances. A method has recently been invented by Dr. A. A. Blandy of Baltimore, and called by him the cheoplastic, by which the teeth are secured in an alloy of great fusibility, and not liable to change its form in cooling. By the specification this alloy may consist of 10 to 20 parts of tin, 1 to 5 of bismuth, 1 to 4 of antimony, and 1 to 2 of silver; to these 5 to 15 parts of cadmium may be added to increase the strength of the alloy. In case an unpleasant taste should be experienced from the mixture, it may be electro-gilded. This recommendation implies a possibility of the alloy being affected by the action of the fluids of the mouth, and time is required for its capability of resisting this action to be fully tested. The alloy is to be run into a mould of the gums, and the plate is thus cast instead of being shaped by swaging. The teeth, previously arranged in the mould, are secured in their places by this melting of the alloy around them.— Another process lately introduced is to dispense with metallic plates, and mould the mineral paste into complete sets, as in making small blocks of teeth. This method is objectionable from the difficulty of procuring a perfect fit, and the liability to entire loss of the set by accidental fracture.—In 1851 the process called continuous gum was invented by Dr. John Allen, late professor in the Ohio college of dental surgery. In this a silicious compound, similar in composition to that of which the teeth are made, but more fusible, is applied in the form of a paste over the fastenings at the back of the teeth, and also in the front, so as entirely to bury the ends of the teeth, as the natural ones are buried in the gums. To withstand the high degree of heat requisite for baking this upon the plate, platinum is substituted for gold. Platinum has beside the advantage of forming at a high heat a close union with the silicious compound, which is spread over the lingual side of the plate as well as over the bases of the teeth. When thoroughly dry, the work is baked at a white heat in the muffle of an assaying furnace. A new application of the paste is then made to fill all the crevices caused by shrinking, and upon this coating are made numerous ridges and depressions with the spatula, which, when afterward covered with the coloring enamel, cause this to assume different shades of the color, and present the appearance of the veins, rugæ, &c., seen upon the natural gums and roof of the mouth. The baking is repeated, and after this the coating of coloring matter, called the gum enamel, is applied, when a third baking completes the process. The process claimed by Dr. Hunter is similar to that above described. The compositions made use of are empirical mixtures of pure silica and feldspar, with suitable flux to produce a fusible compound, possessing sufficient strength, hardness, and permanency of character. The work can easily be repaired when broken, or alterations made when required by changes in the mouth, by building upon it more of the paste and again baking; in this way even the length of the artificial teeth can be increased and new ones introduced. In the same way the artificial processes called cheek restorers were applied by Dr. Allen, which are projecting portions built upon the artificial gums far back in the mouth, and serve to distend the cheeks when these are fallen in. The composition of

the paste for the gums has been perfected by Dr. E. A. L. Roberts of New York, who has largely manufactured it for Dr. Allen, and given it increased density and strength, overcoming in a great measure its brittleness, and causing it most effectually to resist the action of the fluids of the mouth. In the application of these artificial substitutes various kinds of professional talent and mechanical skill are called into play; and the operator, in order to give the natural expression to the mouth, imitating the true colors and proportions of the teeth and of the gums, must even possess a certain degree of that genius and taste which guide the pencil of the artist or the chisel of the sculptor. The mechanical operations connected with the work have led to increased knowledge in the use of plastic compounds, and introduced improved methods of treating the metals employed. (See Blowpipe, Furnace.)

DENTITION. In all the higher animals the teeth are developed directly from the mucous membrane, and are therefore, like hair, nails, feathers, &c., appendages of the skin, and form no part of the true osseous system. As early as the 5th week of fœtal life, according to the observations of Prof. Goodsir, a deep, narrow groove, between the lip and the rudimentary palate in the upper jaw, indicates the future situation of the teeth. Within the next 3 weeks papillæ developed at the bottom of the groove become the germs of the future milk or temporary teeth. In the progress of development the papillæ are enveloped in open follicles, and these again are converted into shut sacs; contemporaneously with these changes, the edges of the dental groove are themselves growing, so that by the 14th week they meet, enclosing the tooth sacs. Within the sacs the papillary pulp is gradually converted into dentine, of which the body of the tooth is composed, while the enamel is formed from a separate pulp connected with the opercula of the sacs. (See Dentistry.) As teeth are required before the jaws have attained their growth, and yet from their structure are incapable of enlarging *pari passu* with the bones in which they are placed, provision is made for a temporary set, which, when they have served their purpose, are replaced by the permanent teeth. As early as the 14th week minute crescentic depressions of mucous membrane may be discovered above and at the inner part of the opercula of the milk teeth; these depressions soon become converted into minute compressed sacs, which gradually sink behind and below the sac of the milk teeth, and in these sacs are developed the first 10 permanent teeth of each jaw; the other 6 are developed in sacs placed posterior to those of the last milk teeth, which are formed in a manner precisely similar to those of the milk teeth themselves. The ossification of the permanent teeth commences a little before birth with that of the first molar, and proceeds during the first 3 years of infancy successively in the incisors, the canines, and the bicuspids. The approach of the time for the eruption of the temporary teeth is announced by an increased secretion of saliva. In the earlier months of infancy the mouth is comparatively dry, but as the teeth shoot into the gums the mouth becomes moist and the child begins to drivel. The progress of dentition is not apparently continuous, but after the eruption of each successive pair a pause of one or two months generally follows. The central incisors commonly pierce the gum in the course of the 7th month after birth, those of the lower jaw preceding the upper ones by a short interval; between the 7th and 10th months the lateral incisors make their appearance; from the 12th to the 14th month the anterior molars, and between the 14th and 20th the canines are cut; and the first dentition is completed between the 18th and 36th months by the protrusion of the posterior molars. Both the time and the order of appearance of the first set of teeth admit of a good deal of variation, their progress being hastened or delayed sometimes for a period of 6 or 7 months, by a lateral incisor, or even a molar or canine tooth, cutting the gum before the appearance of the central incisors. The period of primary dentition is one looked forward to with much anxiety, and is justly regarded as attended with increased risk to the life of the infant. Statistical inquiries show that during its continuance the proportionate mortality becomes much increased, and in the bills of mortality numerous deaths are ascribed to teething alone. It must be remembered, however, that at this time all the functions of the young being are in a state of great activity, and that teething is but one in a series of changes by which the infant is prepared to substitute for the milk provided by its mother, food suitable to the conditions of its future existence. In a healthy infant dentition in itself is attended with little inconvenience and no danger; when the teeth come to distend and stretch the mucous membrane lining the gums, there is probably a little tenderness and pain, some fretfulness, and perhaps slight febrile excitement; but in the absence of other causes of disease, this soon passes over; if, however, the nervous system is unduly excitable, dentition may seriously complicate other maladies. When the process of dentition is advancing normally, it should never be interfered with; when the gum is red, swollen, and painful, scarification may be resorted to with advantage, and may be repeated if necessary, the trifling loss of blood affording relief to the inflamed gum. When the tooth is evidently about to pierce the gum, if the child appears to suffer, it may be freed by cutting down to it with the gum lancet. In cases where convulsions supervene suddenly without an evident cause, if dentition is proceeding actively and the gums are tense and swollen, the gum lancet may be resorted to. In the convulsive affections which take place in children whose nervous systems have been rendered irritable by improper diet, or an impure or vitiated atmosphere, the late Dr. Mar-

shall Hall was a strenuous advocate of the free incision of the gums even when dentition was not making active progress; but in such cases the immediate exciting cause of the convulsions must be sought elsewhere than in the gums, and the attacks are to be relieved by removing the cause when it can be discovered, while their recurrence is guarded against by change of air and a more appropriate diet. Occasionally dentition is attended with a good deal of fever and much derangement of the digestive organs, while a sloughy unhealthy ulceration makes its appearance on the gum over the teeth just about to protrude, or at the edge of the gum of those which have recently been cut. In these cases the gum lancet does positive harm, while they readily yield to a properly regulated diet, and to the use of the chlorate of potash in solution, in doses of one or two grains repeated every 4 hours. During the earlier period of childhood a bony plate or partition separates the permanent from the fangs of the temporary teeth; as the period approaches in which the latter are to replace the former, this partition disappears, and the crown of the enlarged permanent tooth makes its way into the cavity of the temporary fang. As the permanent tooth advances, the fang of the milk tooth is absorbed, not however from any pressure exercised by the one upon the other, the two never coming in contact; and as the crown of the milk tooth falls off, the permanent tooth is ready to replace it. The first anterior or true molar usually appears at about 6½ years; about the same time or a few months later the central permanent incisors appear; the lateral ones are developed at 8, the anterior and posterior bicuspids at 9 and 10, the canines from 11 to 12, the 2d true molars from 12 to 13, and the wisdom teeth from 17 to 19. From the investigations of Mr. Edwin Saunders ("The Teeth a Test of Age, considered with reference to the Factory Children"), it would appear that the 2d dentition furnishes the best physical evidence of the age of children within our reach; in the large majority of instances he found its indications coincided very closely with the real age of the children, and when they failed the extreme deviation was but a year.

DENTON, a N. E. county of Texas, drained by two forks of Trinity river, and occupied partly by prairies and partly by vast forests called the Cross Timbers; area, 900 sq. m.; pop. in 1858, 3,907, of whom 195 were slaves. In 1850 it produced 14,171 bushels of corn, 980 of oats, and 18,728 lbs. of butter. Capital, Denton.

DENUELLE, Dominique Alexandre, a French decorative artist, born in Paris in 1818. He studied under Paul Delaroche and Duban, the architect of the Louvre restoration, and passed several years in Italy. Since 1844, when he first became known, he has been extensively employed in restoring mural paintings in public buildings, many of which have also been decorated from his own designs. He has been employed upon the churches of St. Germain des Prés, Ste. Clotilde, Notre Dame, and many others in Paris, Lyons, Orleans, Beauvais, &c.

DEODAND (Lat. *Deo dandum*, a thing to be given to God). A superstitious practice prevailed in England from the earliest time until a very recent period, whereby a chattel which had been the immediate instrument or cause of death to a human being was forfeited to the king, to be applied by him to pious uses. *Omnia quæ movent ad mortem sunt Deo danda* (all things which while in motion cause death are to be offered to God), is the rule stated by Bracton. It is supposed by Blackstone that the origin of this practice was the religious doctrine of making expiation for the souls of such as were carried off by sudden death. A singular distinction was made between an infant and an adult, viz.: that an infant falling from a cart or horse not being in motion, there was no forfeiture; whereas in the case of an adult the horse or cart was a deodand. Yet if a horse or other animal should of his own motion kill either an infant or adult, or if a cart should run over him, in either case the animal or cart was forfeited as a deodand. Another rule equally inexplicable was, that when a thing not in motion was the occasion of a man's death, only that part which was the immediate cause was forfeited; but if the thing was in motion, then the whole was forfeited; as, if a man was run over by a cart wheel, the whole cart was a deodand. It made no difference although the owner of the chattel was not in fault; it was equally a forfeiture as if he had contributed to the death. This absurd custom gave rise to a clause in indictments, which was held to be essential, viz: a finding by the grand jury what was the instrument of death, and its value; and so also in a verdict of a coroner's jury in cases of homicide. By the act 9 and 10 Victoria, c. 62 (1846), the forfeiture was abolished; and by the act 14 and 15 Victoria, c. 100 (1851), it was declared unnecessary to set forth in indictments the instrument of death.

D'EON, Chevalier. See Eon.

DEPARTURE, in navigation and surveying, the distance apart of two meridians, one drawn through each extremity of a line, such as a ship's course.

DE PEYSTER. I. Johannes, one of the early settlers of New Amsterdam, now New York, born in Haarlem, Holland, in the beginning of the 17th century, died in New York about 1685. He was of a French Huguenot family who took refuge in the United Provinces about the time of the massacre of St. Bartholomew, and in the course of a long life held many offices of trust and honor under Dutch and English colonial rule. During the short period in 1673–'4 in which the Dutch recovered possession of the province, he took a prominent part in the conduct of public affairs, and was one of the last to take the oath of allegiance to the British crown upon the final cession of the New Netherlands to that power; notwithstanding which he was subsequently at different times alderman, deputy mayor, and mayor. At his death, he

was one of the richest citizens in the colony. II. Abraham, eldest son of the preceding, born in New York, July 8, 1658, died there, Aug. 10, 1728. He was by profession a merchant, and amassed considerable wealth in lands and goods; and also filled many important public offices after the final cession of the New Netherlands to Great Britain. Between 1691 and 1695 he was mayor of New York, and subsequently became chief justice of the province, and president of the king's council, in which latter capacity in 1701 he acted as colonial governor. He was also colonel of the forces of the city and county of New York, and treasurer of the provinces of New York and New Jersey. He possessed great influence in the councils of his native city from his administrative talent, integrity, and liberal sentiments, and was the intimate friend and correspondent of William Penn, and of the colonial governor, the earl of Bellamont. The mansion erected by him in Pearl street in 1695, which was at one time the head-quarters of General Washington, remained standing until 1856. The bell presented by him to the middle Dutch church in Nassau street a short time before his death, now hangs in the Reformed Dutch church in Lafayette place.—Of the other children of Johannes De Peyster, Johannes filled the mayoralty chair of New York, Isaac was member of the provincial legislature, and Cornelius was the first chamberlain of the city of New York, beside filling various other public offices. One of his granddaughters was the mother of Major-General William Alexander, the claimant of the Scottish earldom of Stirling.—Of the descendants of Col. Abraham De Peyster, his eldest son, Abraham, was for many years treasurer of the province of New York; and his great-grandson, Abraham, commanded a detachment of royal troops under Col. Ferguson at the battle of King's Mountain. After the war he was treasurer of the province of New Brunswick, and commander of the militia. James, a brother of the preceding, was also an officer in the British army, and fell at the battle of Lincelles, in the Netherlands, in 1793. III. Arent Schuyler, grandson of Col. Abraham De Peyster, and a colonel in the British army, born in New York, June 27, 1736, died at Dumfries, Scotland, in Nov. 1832. He entered the 8th or king's regiment of foot in 1755, served in various parts of North America under his uncle, Col. Peter Schuyler, and commanded at Detroit, Michilimackinac, and various places in Upper Canada, during the American revolutionary war. The Indian tribes of the north-west were then decidedly hostile to the British government, but the prudent measures adopted by Col. De Peyster tended to conciliate and finally to detach them entirely from the American cause. To his influence over the Indians several American missionaries and their families were on one occasion indebted for the preservation of their lives. Having risen to the rank of colonel, and commanded his regiment for many years, he retired to Dumfries, the native town of his wife, where he resided until his death. During the French revolution he was instrumental in embodying and training the 1st regiment of Dumfries volunteers, of which Robert Burns was an original member. He was on terms of friendship with Burns, who addressed to him one of his fugitive pieces, and with whom he once carried on a poetical controversy in the columns of the "Dumfries Journal." He died as full of honors as of years, having held the king's commission upward of 77 years, and being probably at the time the oldest officer in the service. His nephew, Captain Arent Schuyler De Peyster, was an American navigator, who sailed several times around the globe, and in a passage from the western coast of America to Calcutta, discovered a group of islands, called after him the De Peyster or Peyster islands.

DEPOSITION, in law, the testimony of a witness reduced to writing in due form of law, taken by virtue of a commission or other authority of a competent tribunal. When taken by commission, depositions are usually in answer to questions upon the examination in chief, and upon cross-examination, prepared and submitted to the court from which the commission issues. In other cases they are taken by consent of counsel or in due course of law, the privilege of cross-examination being always preserved, except in some cases where depositions of matters within the knowledge of persons of great age are allowed to be taken for the purpose of perpetuating their testimony, and in cases where immediate death by violence is expected. This must, when possible, be sworn to and signed by the witness. In the United States, compulsory process is usually allowed to procure this evidence.—In ecclesiastical law, deposition is the act of depriving a clergyman by a competent tribunal of his clerical orders, in punishment of some offence, and to prevent his acting in his clerical character.

DEPPING, Georges Bernard, a French naturalist and historian, born at Münster, Westphalia, May 11, 1784, died in Paris, Sept. 5, 1853. He went to Paris in 1803, and first devoted himself to teaching, and afterward to miscellaneous literary labor. His juvenile works, *Les soirées d'hiver* (3d ed. 1832; translated into many European languages) and *Merveilles et beautés de la nature en France* (9th ed. 1843), became as popular abroad as at home. He joined Malte Brun in his efforts to promote the knowledge of geography in France, and wrote a great number of geographical works. His intimacy with the Danish poets Baggesen and Oehlenschläger led him to apply himself to the study of Scandinavian literature, history, and archæology, and so successfully that he won the prize offered by the institute in 1820 for the best work on the maritime expeditions of the Normans into France in the 10th century. This work was followed by his "History of Normandy from 1066 to 1204" (1835). Among the most important of his other writings are a "History of the

Commerce between the Levant and Europe from the time of the Crusades to the Colonization of America" (1830); and a "History of the Jews in the Middle Ages" (1834).

DEPTFORD, a town and naval arsenal in Kent and Surrey, England, on the right bank of the Thames, at the mouth of the Ravensbourne, on the Croydon and Greenwich railways, and at the junction of the Croydon and Surrey canals, 3 m. S. E. from London bridge, and contiguous to Greenwich; pop. in 1851, 27,896. It contains a royal naval school incorporated in 1840, and 2 ancient hospitals for decayed pilots and shipmasters or their widows. Its principal feature, however, is the dock yard, established by Henry VIII., and now enclosing an area of 31 acres. There are 3 slips for ships of the line on the river front, 2 for smaller vessels opening into a basin 260 by 220 feet, and 2 dry docks, one communicating with the basin, and the other, a double dock, with the Thames. Adjoining the dock yard is the victualling yard, containing sheep and cattle pens, slaughter houses, salting establishments, a mill of great capacity, bakeries, a brewery, and a cooperage in which casks are made by machinery. The number of persons employed in time of war in the docks has been about 1,500, and in the victualling yard about 1,200.

DE QUINCEY, Thomas, an English author, often styled "the English opium-eater," from the remarkable personal experiences detailed in his celebrated work bearing that title, born in Greenhay, a suburb of Manchester, in 1786. Many of his writings are autobiographical, but in the minute account he has given of his adventures and sufferings, fiction is supposed to be mixed with fact to such a degree as to render it impossible in many cases to discriminate between them. He was the 5th child of a merchant who spent most of his time at foreign ports, and who at his death in 1793 left to his family a fortune of £1,600 a year. His childhood was chiefly passed in rural seclusion, with 3 sisters for playmates. The death of one of these when he was 2½ years old caused him not so much sorrow as a sad perplexity; it appalled him by its mystery, but he was solaced by a trust that she would return again like the crocuses and roses. A few years later, the death of a second sister overwhelmed him with grief, and the sentiments of love and religion which it awoke were nursed by him in silent reverie, and deepened the naturally solemn tone of his mind. "If," he says, "I should return thanks to Providence for all the separate blessings of my early situation, these four I should single out as worthy of special commemoration: that I lived in rustic solitude; that this solitude was in England; that my infant feelings were moulded by the gentlest of sisters, and not by horrid pugilistic brothers; finally, that I and they were dutiful and loving members of a pure, holy, and magnificent church." He was sent to various schools, and early distinguished himself by his proficiency in Greek; at the grammar school of Bath, where he studied from his 12th till his 14th year, the master said of him that he "could harangue an Athenian mob." He was transferred to a school at Winkfield, where he remained a year in discontent, entreating his guardian to send him to the university, but in vain, though the income of his patrimony was sufficient for his support. Resolved, however, to be no longer numbered among school boys, he borrowed from a lady of rank 10 guineas, ran away from school with a volume of Euripides in his pocket, and by accident directed his wanderings toward North Wales. The inns rapidly exhausted his money, and after a few weeks he was obliged first to limit himself to one meal a day, and then to subsist only on blackberries, hips, haws, and casual hospitalities. He contrived in May, 1800, to obtain a passage to London, and there a fiercer stage of his sufferings began. For 16 weeks he constantly endured the physical anguish of hunger, and that he did not sink under his torments he ascribes to his constant exposure to the open air, since he was houseless, seldom sleeping under a roof. He was at length permitted by an eccentric character to sleep in a large unoccupied house, where he found a forsaken, friendless, hunger-bitten girl, apparently 10 years of age, for his companion, who rejoiced in obtaining a protector during the darkness amid the rats and ghosts. He has written pathetic sketches of his associations at this time with some of the refuse members of London society. He had in vain resorted to a Jew for an advance of money on the strength of his future expectations, when at length an opening was made for reconciliation with his friends; and he attended school and visited in different parts of England and Ireland till he went to Oxford in Dec. 1803. After having been an unknown and unacknowledged vagrant, a houseless wanderer in Wales, and a solitary roamer in the streets of London, he speaks of himself as now for the first time becoming an object of notice to a large society, and burdened with the anxieties of a man and of a member of the world. He was a student at Oxford till 1808. He first resorted to opium on a visit to London in the autumn of 1804, with a view of lulling the pains of rheumatism. He took it; and in an hour, "O heavens! what a revulsion! what an upheaving from its lowest depths of the inner spirit! what an apocalypse of the world within me! That my pains had vanished was now a trifle in my eyes; this negative effect was swallowed up in the immensity of those positive effects which had opened before me, in the abyss of divine enjoyment thus suddenly revealed." He says that for 10 years he "lived on the earth the life of a demiurgus, and kept the keys of paradise." It was his custom to drink laudanum either on a Tuesday or Saturday night once in 3 weeks. On Tuesday night he went to the opera, where in the elaborate harmony and scenic display he saw unfolded before him, as in a piece of arras-work, the whole of his past life, with its passions exalted, spiritual-

ized, and sublimed; not as if recalled by an act of memory, but as if present and incarnated in the music. On Saturday night he used to wander forth through the markets of London, where the poor were expending their money, and listen to the consultations of family parties on their ways and means, making himself familiar with their wishes, difficulties, and opinions, and philosophically observing as he listened that expressions of patience, hope, and tranquillity were far more common than murmurs of discontent. Such were his delights, and such were the pictures which at a later time tyrannized over his dreams. In 1809, soon after leaving the university, he took the cottage at Grasmere, among the lakes and mountains of Westmoreland, which Wordsworth had occupied before him; and he retained it 27 years. Among his associates, with whom he had formed acquaintance in prior visits, were Wordsworth and Coleridge at Grasmere, Southey at Keswick, Charles Lloyd at Brathay, and Wilson at Elleray. He often visited London, Bath, and Edinburgh; his most intimate friend in London being for many years the celebrated peripatetic known as "Walking Stewart." He was occupied especially with the study of German literature and philosophy, made translations from Lessing and Richter, and was among the first in England to interpret Kant, Fichte, and Schelling. Though he took opium on Saturday nights, it had not disordered his health, and he was ignorant and unsuspicious of its avenging horrors. But in 1813 an irritation of the stomach, the consequence of his early sufferings, returned with a violence which yielded to no remedies but opium. From this time he became a regular and confirmed opium-eater, taking it daily, and the first effect of this change was that black vapors seemed to roll away from his brain, his mind resumed its functions, and a latter spring came to close up the season of his youth. But within a year began his "Iliad of woes." It had been the aim of his whole life, with reference to which he had directed all his intellectual labors, to construct one single work, to which he purposed giving the title of an unfinished work of Spinoza, *De Emendatione Humani Intellectus*. The studies of many years had laid the foundation, but he could not command the efforts to rear the superstructure. In what he terms his state of imbecility he turned his attention for amusement to political economy. He welcomed the treatise of Ricardo in 1819 as the first profound work on the subject, and it roused him to an activity which enabled him to draw up his "Prolegomena to all Future Systems of Political Economy." Yet opium paralyzed his efforts to complete even that short work. He failed to accomplish the preface, the arrangements for its publication were countermanded, and it first appeared in 1824 under the title of "Templars' Dialogues." It is one of the most thorough, as well as briefest exhibitions of the Ricardian theory of value. Seldom could he prevail on himself to write even a letter. A change took place in his contemplations, and in his dreams. He was inclined to solitude and reverie, and mentions that on summer nights at his open window, overlooking the town and sea at a little distance before him, he often sat from sunset to sunrise, motionless, and without wishing to move. While lying awake, he could see vast processions pass along in mournful pomp, friezes of never-ending processions, that seemed to him as sad and solemn as if they were histories of "times before Œdipus or Priam, before Tyre, before Memphis;" and in his dreams a theatre seemed suddenly opened and lighted up within his brain, which presented nightly spectacles of more than earthly splendor. Space seemed immeasurably expanded, buildings and landscapes assumed proportions too vast for the scope of the eye, time became infinitely elastic, stretching out to boundless and vanishing termini, and a single night would leave the impressions of millennia passed in that time. With deep-seated anxiety and gloomy melancholy he seemed every night to descend literally into chasms and sunless abysses, depths below depths from which it appeared hopeless that he could ever reascend. From the gorgeous scenery and terrific events of his dreams he often awoke in struggles, crying aloud: "I will sleep no more." Twice he triumphed over the physical necessity for opium, and twice he relapsed. In a third attempt he found it impossible to retrace his steps, and in the imagery of his dreams he "saw through vast avenues of gloom those towering gates of ingress, which hitherto had always seemed to stand open, now at last barred against his retreat, and hung with funeral crape." In 1821 he went to London with literary purposes, and, as collaborator in the "London Magazine," became at once associated with Charles Lamb, Hazlitt, Allan Cunningham, Hood, Cary (the translator of Dante), and with other authors. His "Confessions of an English Opium-Eater" appeared in that periodical in 1821, and in a volume in 1822. They immediately obtained for him a high reputation, and have remained his most powerful and artistic production during a long career of authorship. He has been a frequent contributor to British periodicals, chiefly to "Blackwood's Magazine," "Tait's Edinburgh Magazine," and the "North British Review," of autobiographical sketches, literary reminiscences, miscellaneous essays, and historical, philosophical, and critical discussions. He also furnished several articles to the "Encyclopædia Britannica." The notices of his distinguished contemporaries and associates which give interest to several of his writings, it has been said, would have been more appropriate if marked by greater reserve. All his works show a wide range of learning and speculation, a delicate and subtle critical faculty, and a felicitous selection of words. As improvisations they would be admirable displays of mental power, but most of them are so unartistically constructed, the main idea and purpose being lost by unceasing discursions, that they are ex-

cellent only in fragments and passages. His highest and most peculiar merit is as a writer of imaginative and highly impassioned prose, the best examples of which are contained in his "Confessions," and "Suspiria de Profundis." Such are his splendid personifications of those various forms or powers of sorrow which hold dominion over man and human life: "the three ladies of sorrow, our lady of tears, our lady of sighs, and our lady of darkness." After alternating for a time between the lakes and London, Mr. De Quincey has since 1843 resided at Lasswade, a village about 12 miles from Edinburgh. In person he is described as far from prepossessing, being diminutive in his stature and awkward in his movements, with a shrivelled and yellow parchment-like skin. He daily performs set tasks of walking in his garden, and often disappears untraced for several days together from his home. He has offered his body after death for dissection, as a contribution to physiological science, believing, or affecting to believe, that the dreadful gnawing of the stomach which he experiences is caused by the ravages of a living animal. His works have been collected in Boston (21 vols., 1851–'59), and a select edition is now (April, 1859) publishing in London and Edinburgh.

DERA GHAZEE KHAN, a large town of the Punjaub, 4 m. from the right or W. bank of the Indus, in the district of Damaun; pop. about 25,000, of whom one-half are Hindoos, and one-half Mohammedans. It contains a dirty, ill-built bazaar with 1,600 shops. It has manufactories of silk, cotton, and mixed fabrics, and cutlery to the estimated amount of $100,000 yearly. The surrounding country is fertile, producing sugar, cotton, indigo, and excellent fruits.

DERAYEH, El, a town of Arabia, in the province of Nedjed, lat. 25° 15′ N., long. 56° 80′ E. It lies in a fertile and well watered valley at the foot of Mount Khoor, was strongly fortified in the oriental style, and contained about 15,000 inhabitants, 30 mosques, and 30 schools, in the earlier part of this century, when it was famous throughout the Mohammedan world as the capital and stronghold of the Wahabees. In 1819 it was taken and destroyed by Ibrahim Pasha, after a siege of 7 months.

DERBEND, or Derbent, a fortified town of Russian Daghestan, on the W. shore of the Caspian sea, lat. 42° 12′ N., long. 48° 25′ E.; pop. about 12,000, consisting of Georgians, Armenians, and Jews. It is built in the pass of Derbend, the ancient Albaniæ Portæ, lying between the sea and the extremity of a spur of the Caucasus. It is defended on the N. and S. by walls of great strength with 2 iron gates, through which the road passes, and from which it has its name, signifying "closed gates." The pass was fortified by the first Darius against the Scythians, and the present walls are said to have been built by Chosroes. It was afterward taken by the Saracens, recovered by the Persians, captured by Russia in 1722, restored to Persia in 1735, and taken again in 1795 by the Russians, who have kept it since.

DERBY, a parliamentary and municipal borough and the county town of Derbyshire, England, on the Derwent, which is navigable hence to its junction with the Trent, distant N. N. W. from London 132 m. by the London and Northwestern and Midland Counties railways; pop. in 1851, 40,609. There are 8 churches, a Catholic cathedral, and 13 dissenting chapels. The free grammar school, said to be one of the oldest institutions of the kind in England, has 10 exhibitions to Emmanuel college, Oxford. There are 6 national, several British, a female normal, a diocesan, a Wesleyan Methodist, and 2 infant schools, a library, a mechanics' institute, and a philosophical society founded by Dr. Darwin. One of the most interesting features of the town is a botanical and pleasure garden called the arboretum, founded by the liberality of Mr. Joseph Strutt, a citizen of Derby, and laid out with great taste, at the donor's expense, by the late J. C. Loudon. The manufactures are extensive, and embrace silk, lace, cotton, porcelain, jewelry, carriages, iron boilers, iron plates, red and white lead, sheet lead, &c. Various beautiful ornaments are made of the marbles, spars, and petrifactions found in the vicinity.

DERBY, Edward Geoffrey Smith Stanley, 14th earl of, and Baron Stanley, a British statesman, born at Knowsley Park, Lancashire, March 29, 1799. At an early age he was sent to Eton college, whence, after the usual residence at that institution, he was removed to the university of Oxford, and entered as a student of Christchurch. Although his academic career was more than ordinarily distinguished, he was never graduated. He entered parliament in 1821 as member for Stockbridge, and made his maiden speech on the Manchester gas-light bill, March 30, 1824, of which Hansard remarks (vol. xi. p. 11), that Mr. Stanley addressed the house "in a maiden speech of much clearness and ability." He soon took rank in the house of commons among the ablest debaters and most prominent leaders of the whig opposition to the ministry of the earl of Liverpool. He was elected member for the town of Preston, Lancashire, in 1826, and on March 11, 1827, took office as under secretary for the colonies in George Canning's administration, which office he continued to hold after the death of that great statesman, in the Goderich (earl of Ripon) cabinet, until its dissolution in Jan. 1828. During the 3 years of the Wellington government which followed, Mr. Stanley was among the first and most eloquent of the prominent orators and statesmen who then occupied seats in the popular branch of the British legislature. On the formation of the reform cabinet of Lord Grey in 1830, he was appointed to the arduous and responsible office of chief secretary for Ireland, with a seat in the cabinet, an honor rarely united with that appointment. The acceptance of office having vacated his seat in parliament, on presenting himself to the electors of Preston for reëlection, he was de-

feated by the radical agitator Henry Hunt, but was soon afterward returned, by the retirement of Sir Hussey Vivian, for the borough of Windsor, which he continued to represent until 1832, when he was elected for one of the divisions of Lancashire. In the great parliamentary struggle of 1832–'3, which resulted in the passage of the reform bill, the church temporalities bill, and the bill to establish national education in Ireland, Mr. Stanley took a brilliant and effective part. His speeches during that stormy session, in reply to the fierce assaults of Daniel O'Connell, Richard Lalor Sheil, and others, are splendid efforts of parliamentary eloquence. In 1833 Mr. Stanley exchanged the troublesome office of chief secretary for Ireland for that of secretary of state for the colonies. He was nominated to this post with the special object of carrying the abolition of slavery in the West Indies, which was effected under his auspices. In the following year, on the death of his grandfather and the succession of his father to the earldom, he became known by the courtesy title of Lord Stanley, and in the same year retired from the cabinet in company with Sir James Graham, the earl of Ripon, and the duke of Richmond, in consequence of his and his three colleagues' nonconcurrence with the ministerial proposition to appropriate the surplus funds of the Irish church establishment for secular education. In the brief administration of Sir Robert Peel (Dec. 1834, to April, 1835), Lord Stanley refused to take office. But long before the 6 years of the whig dominion under Lord Melbourne had elapsed, he and his followers, facetiously known as "the Canning leaven of the whig administration," were found voting steadily with the conservative opposition, as avowed members of the conservative party. In 1841 the whigs went out of office, and Sir Robert Peel formed a cabinet in which Lord Stanley occupied a seat as colonial secretary. In 1844, while his father was still living, he was summoned by writ to the house of peers as Baron Stanley of Bickerstaffe, and assumed the leadership of the conservative party in that body. When Sir Robert Peel resolved in 1845 to adopt a free trade policy, and remove prohibitive duties on foreign grain and breadstuffs, Lord Stanley left the cabinet and became the leader of the protectionist opposition. When, in Dec. 1845, Sir Robert tendered his resignation to the queen, Lord Stanley was invited by her majesty, at the instance of Lord John Russell, to form a protectionist cabinet, but he resolutely declined the offer. During the 6 years of Lord John Russell's tenure of the premiership, Lord Stanley added to his already high fame as an orator and a statesman, by his frank, manly, and magnanimous course as leader of the opposition in the hereditary branch of the legislature. His speech on the Irish poor laws in 1849, his speech on the affairs of Greece in 1850, and his famous explanation of the reasons why he declined the premiership when offered to him in Feb. 1851, when Lord John Russell's ministry were defeated in the house of commons on Mr. Locke King's motion for an extension of the franchise, are among the most remarkable of his forensic efforts. On June 30, 1851, on the death of his father at the advanced age of 76, he succeeded to the earldom and the vast ancestral estates in England and Ireland which are attached to it. On Feb. 20, 1852, Lord John Russell having sustained another defeat on the militia bill, Lord Derby was again called by the queen to construct a cabinet, and succeeded in performing the task within a week after the overthrow of the whig chieftain. In July of the same year parliament was dissolved, and the new parliament assembled in December. On one of the first test divisions the ministry were defeated by a majority of 19 in an unusually full house, and after 10 months' tenure of office, they were succeeded by the so-called coalition cabinet, of which the earl of Aberdeen was the head. When in his turn this last mentioned nobleman was driven from power, the seals of office were again offered to and declined by Lord Derby, and finally intrusted to the care of Lord Palmerston, who continued to hold them until 1858, when, by the same majority of 19 by which Lord Derby was overthrown 6 years before, Palmerston was defeated by the adoption of Mr. Milner Gibson's amendment on the second reading of the conspiracy to murder bill. On the resignation of Lord Palmerston, Lord Derby was again "sent for" by the queen to form the cabinet over which, with one or two unimportant changes, he still (April, 1859) continues to preside. Lord Derby was elected chancellor of the university of Oxford on the death of the duke of Wellington, is an elder brother of the Trinity house, governor of the Charter house, a trustee of the British museum and of the Hunterian museum, and fills other honorary posts. On May 31, 1825, he married the Hon. Emma Caroline Wilbraham, 2d daughter of Edward, Lord Skelmersdale, by whom, beside two sons and one daughter who died in infancy, he has issue, the Right Hon. Edward, Lord Stanley, now secretary of state for India, the lady Emma Charlotte, and the Hon. Frederic Arthur Stanley, an officer in the British army.—The earldom of Derby was conferred by Henry VII. in 1485 on the then representative of the old and heroic family of Stanley of Lancashire, for acts of prowess and devotion at the battle of Bosworth. For more than 2 centuries the earls of Derby were sovereigns of the isle of Man, under the suzerainty of the British king, and it was not until the reign of George III. that the sovereignty of that island was transferred to the British crown.

DERBYSHIRE, a central co. of England, consisting of a level or moderately hilly district, abounding in fine scenery, fertile, well cultivated, and rich in minerals; area, 1,028 sq. m.; pop. in 1851, 296,084. It is watered by the Derwent, Trent, Dove, Wye, Erewash, and Rother. The S. and E. parts produce wheat, barley, and other kinds of grain; the N. part, where the surface is more hilly, and the climate colder, is occupied chiefly by oat fields and pas-

tures. The elevated region called the High peak, consisting of a succession of bleak hills, some of which rise 2,000 feet above sea level, interspersed with narrow valleys, is famous for its romantic scenery. Dairy husbandry is carried on in nearly all quarters of the county, and yields upward of 2,000 tons of cheese every year. Among the hills are reared small sheep, and a breed of light, slender horses. Among the minerals are coal, iron, lead, zinc, copper, gypsum, black and variegated marble, fluor spar, small crystals called Derbyshire diamonds, chalcedony, jasper, and a few onyxes. The coal field covers an area of about 190,000 acres, and belongs to the same great field which extends over part of the West Riding of Yorkshire and part of Nottinghamshire. The lead mines have from time immemorial been let on lease, and are the subjects of several very ancient and peculiar laws. Courts for the adjustment of disputes occurring and debts contracted in working these mines are established in each mining district, and are presided over by the lessee's steward, assisted by 24 jurymen. There is another officer, called the barmaster, whose duty it is to put miners into possession of veins which they may have discovered, and to collect the rent due the lessee of the crown or the lord of the manor. Derbyshire is traversed by the Grand Trunk, or Trent and Mersey, the Erewash, the Derby, the Cromford, the Nutbrook, the Chesterfield, the Peak forest, and the Ashby de la Zouch canals, and by the Cromford and High Peak, the North Midland, the Midland Counties, the Birmingham and Derby grand junction, and several branch railways, beside a number of private railways for the transportation of produce of the mines. The manufactures are important, and comprise cotton, silk, calico, cambric, fustian, muslin, tape, candle wicks, machinery, agricultural implements, leather, hats, paper, and porcelain. In the mountain district there are numerous tepid mineral springs.

DERBYSHIRE SPAR, a variety of fluor spar found in Derbyshire, England, which is distinguished by its fine shades of purple, blue, red, and yellow. These, together with the soundness of the stone, render it well adapted for ornamental purposes. The manufacture of cups, tables, vases, inkstands, and other objects, is extensively carried on in several towns in the county, as at Derby, Buxton, Castleton, Bakewell, &c. The stone takes a high polish for one so soft; but the property which renders it easy to be worked, makes it liable to be soon defaced by scratches. It is found near Castleton in fissures in the limestone rocks.

DERFFLINGER, Georg von (originally Dörfling), a general of the great elector of Brandenburg, born in Bohemia in March, 1606, died Feb. 4, 1695. A tailor's apprentice, he took service as a soldier, and fought at the battle of Prague, after which he entered the Swedish army as an officer under Gustavus Adolphus. He served under Bauer and Torstensen, contributed to the Swedish victory at Leipsic in 1642, and was raised to the rank of major-general. Afterward he entered the service of Brandenburg, and distinguished himself against the Poles, Swedes, and French. In 1670 he became field marshal, and in 1674 baron of the German empire; routed the Swedes near Rathenau, June 15, 1675, and at Fehrbellin 3 days afterward, and secured the greater portion of Pomerania for the elector. In the winter campaign of 1678–'9 he caused 9,000 soldiers and 30 guns to cross the ice on sleds as far as Tilsit, and routed the Swedes under Horn near the latter city.

DERG, Lough, a lake in the co. of Donegal, Ireland, about 7 m. S. E. of Donegal, 3 m. long, and 2½ m. wide at the broadest part. It is enclosed on all sides except the S. by steep, barren mountains, which give a wild and desolate character to the surrounding scenery. Its shores are rough and precipitous. It lies 467 feet above the level of the sea, and is 75 feet deep. A multitude of little islands dot its surface, one of which, called Station island, about an acre in extent, contains a cave known as St. Patrick's Purgatory, to which between 10,000 and 15,000 Roman Catholic pilgrims from all parts of Ireland resort annually between Aug. 1 and 15. They remain on the island, which contains 2 chapels, a house for the priests, and a few cabins, from 3 to 9 days, their only food during that time being bread and water.

DERHAM, William, an English divine and natural philosopher, born at Stoughton, near Worcester, in Nov. 1657, died at Upminster, near London, April 5, 1735. The most important of his published works are: "The Artificial Clockmaker" (4th edition, 1734); "Physico-Theology" (16 discourses preached at Boyle's lecture, 1711), and "Astro-Theology" (1714), designed to prove the existence and attributes of God from an examination respectively of the works of creation and of the heavenly bodies; and "Christo-Theology" (1730), a sermon to prove the divine origin of Christianity.

DERIVATION, in modern algebra, is the mode of developing one function from another, according to some fixed law. By a function is here meant any algebraical expression of a quantity dependent for its value upon other quantities. The most usual, and perhaps the most important derivative functions, are Differentials and Integrals, which see.

DERMODY, Thomas, an Irish poet, born at Ennis in 1775, died at Sydenham, near London, in 1802. His father was a schoolmaster, and is said to have employed him while only in his 9th year as his assistant in teaching Latin and Greek. Thomas, however, soon after ran away from home, enlisted in the army, and served in the expedition to Holland under the earl of Moira, who promoted him to a second lieutenantcy; but by his intemperate habits he lost the favor of his patron, and afterward lived some time in London, and died in extreme poverty. A small volume of poems written by him in his 13th year appeared in 1792. In 1793 he pub-

lished a pamphlet on the French revolution, to which was appended a poem entitled "The Reform."

DERVISE, a Persian word meaning poor or indigent, used in Mohammedan countries substantially like the Arabic *fakir*, to designate a class of religious people who in some respects resemble the monks of Christianity. Their rule commands an austere piety, religious contemplation, poverty, chastity, modesty, patience, humility, and charity. They live in convents under the direction of a *sheikh*, but are allowed to marry, on the condition, however, of passing two nights of the week among their associates. They live by the labor of their hands, mendicity being forbidden, except in the order of the Bektashis, but their convents have generally been supplied by the donations of the sultans. Beside the fast of the Ramadan, they observe one weekly fast from morning to sunset. They hold religious meetings on Tuesdays and Fridays, in which they perform, to the sound of a flute, sacred dances, whirling around with extreme velocity, and stopping at once when the music ceases. Some lead a vagrant life, and traverse all the countries of the East from the Mediterranean to the Ganges, being lodged and fed in the convents of their order. They wear coarse robes, and walk bare-legged with the breast uncovered. The use of intoxicating liquors, as well as of opium, is stated to be common among them. In general they are said to enjoy little esteem among the people, who despise them as idlers. Some of them also act as jugglers, sorcerers, and charmers. The order of the Rufaïs, founded in the 12th century by Sheikh Ahmed Rufaï, is distinguished by fanatical excesses of self-mortification. At their assemblies some are seen holding a piece of red-hot iron between their teeth, others making incisions in their flesh. The Calenders are remarkable for their strange dress, sometimes consisting of a sheep's or tiger's skin; they wear feathers in their ears, and frequently go about half naked. The principal order is that of the Maulavis, whose chief convent is at Konieh, in Asia Minor. The origin of the dervises can be traced back to the first centuries of the Hegira. The foundation of some of the orders is attributed to Abubekr, Ali, and others; and passages of the Koran, which extol the merits of poverty and an independent, contemplative life, are quoted in support of the institution, which tradition also represents as having existed in the times of Elijah, of Jacob, and even of Seth.

DERWENT, the name of several rivers of England. I. A river of Cumberland, 32 m. long, rising in the district of Borrowdale, and flowing N. and then S. W. into the Irish sea, which it enters near Workington. It forms the lake of Derwentwater near Keswick, where it is joined by the Greta; expands into Bassenthwaite-water at the town of that name, and receives the river Cocker at Cockermouth. Its banks abound in rich and varied scenery. II. A river of Derbyshire, rising in a place called "the trough," in the mountains which extend along the N. boundary of the county, and uniting with the Trent near the borders of Leicestershire, after a course of about 50 m. Its general course is S. E. It passes Chatsworth house and the towns of Matlock, Belper, and Derby. Its scenery, particularly in the upper part, is beautifully diversified. The Wye is its largest tributary. III. A river of Yorkshire, East Riding, rising near Harwood dale, flowing nearly S. with many windings, and falling into the Ouse at Barmby, after a course of about 60 m. It is navigable to Malton, 27 m. above its mouth.

DERWENT, a river rising near the centre of Van Diemen's Land, flowing S. E. into the district of Norfolk, and entering the S. Pacific ocean through an estuary which separates the districts of Hobart Town and Richmond. The estuary is about 4 m. broad at its entrance, and retains this width for a distance of 6 or 8 m. inland. On an island at its mouth is a lighthouse 70 feet above the sea.

DERWENTWATER, James Radcliffe, earl of, a leader in the English rebellion of 1715, born in 1689, beheaded Feb. 24, 1716. He belonged to an ancient Catholic family in Northumberland. Sir Francis Radcliffe was created earl of Derwentwater by James II. in 1688, and his son Francis married a natural daughter of Charles II. His grandson James was brought up at St. Germain, and succeeded to the earldom in 1705. Personal attachment to the members of the Stuart family, as well as political principle, disposed the earl of Derwentwater to attempt the restoration of that house to the throne of England, and he entered into arrangements for that purpose with many other gentlemen and noblemen of the north and west of England. The plot was betrayed to the government of George I., who immediately suspended the *habeas corpus* act and issued warrants against the suspected. The standard of rebellion having been raised in Scotland, Lord Derwentwater, at the instigation of his countess, as it is said, commenced the movement in England, Oct. 6, 1715. The death of Louis XIV. disappointed the hopes of foreign aid, and at the first rendezvous there were but 60 persons present. Mr. Forster, member of parliament for Cumberland, was chosen leader, a selection in which his Protestantism was alone considered. They soon marched south, and approached Newcastle, which they failed in surprising. Volunteers came in slowly, and they were even compelled to decline the services of some for want of arms. Being joined by a party from Scotland, who were somewhat better, though imperfectly, equipped, they retreated toward the border, where they were joined by another body, under Mackintosh. The combined army now amounted to about 2,000 men. Two plans were proposed: one to take the southern Scottish towns and to operate against the duke of Argyle; the other to march south and encounter Gen. Carpenter, who was at the head of an inferior body of hastily levied troops. But the Englishmen would not go into Scotland, nor

the highlanders into England. Marching along the border, the dissension soon came to an open rupture. Lord Derwentwater endeavored to compromise matters, and advised the advance into Scotland; and finally they marched against Dumfries, whose inhabitants threw up intrenchments to oppose them. Without fighting, it was decided to march into England. At this a large number of the men retired at once, while the earl of Wintoun, Lord Derwentwater, and others accompanied the advance rather than give up the cause. At Penrith they were encountered by the *posse comitatus* of Cumberland, headed by the resident nobles and gentry. But this body fled on getting sight of the rebels, who continued their march, seizing the public funds where they could. They were joined by a small party of Lancashire gentlemen, and being informed that Manchester had proclaimed King James, they advanced toward that town. They occupied Lancaster, and afterward Preston, which Stanhope's regiment of dragoons evacuated on their approach. Here they received an accession of about 1,200 gentlemen and peasants, mostly unarmed and undisciplined. But Wills was now advancing against them, and Carpenter was closing in on their rear. The insurgents were totally ignorant of their critical position, which was only revealed by a letter from a private friend to Lord Derwentwater. Its contents were at once communicated to Forster, who was completely paralyzed by it. Lord Derwentwater and others threw up some barricades, but neglected to defend the approaches to the town, where a good resistance might have been made. The first attack of Wills was beaten back with considerable loss. Lord Derwentwater and his brother Charles Radcliffe showing great courage. The arrival of Carpenter made affairs desperate. The Scots were determined to sell their lives dearly, and in this they were joined by Lord Derwentwater; but the English commander Forster and others of his countrymen, dismayed at their hopeless situation, sent a secret message to treat for a surrender. After some difficulty Wills was brought to promise to spare their lives if they would surrender at discretion, and the following day these hard terms were accepted, and the royal troops entered the place. Little mercy was shown by the government; many of the common men were sent to the plantations in America, and the more important prisoners were carried to London. Lord Derwentwater was impeached and brought to trial, Jan. 19, 1716. He pleaded guilty, and threw himself on the mercy of the crown, alleging his youth and inexperience as an excuse; he was condemned to death as a traitor. The greatest efforts were made to obtain his pardon. His wife had a personal interview with the king, but to no purpose. Endeavors were made in both houses of parliament to obtain a reprieve, which was granted for two of the prisoners, Lords Carnwath and Widdrington, but the 3 others were ordered for immediate execution. Lord Nithisdale, by the stratagem of his devoted wife, succeeded in making his escape from the tower, but Lord Derwentwater was beheaded on Tower hill. He died with firmness, protesting his loyalty to James III., and asserting that "dishonorable terms had been proposed to him as the price of his life, which he had refused to accept." The estates of Derwentwater were confiscated, and afterward settled on the hospital for seamen at Greenwich. The body of the earl was conveyed by night through the country to his ancestral dwelling, and there buried. In 1805 the coffin was opened and the body found entire, and the head lying by it still showed the marks of the axe.—The countess of Derwentwater died at the age of 30, of small pox, in Deershaven, Flanders.

DERZHAVIN, Gabriel Romanovitch, a Russian lyrical poet, born in Kasan, July 3, 1743, died July 6, 1816, gained distinction in the military and civil service, was made secretary of state in 1791 by Catharine II., with whom he ingratiated himself by his panegyrical odes, minister of justice in 1802, and retired in the following year on a full-pay pension. Many of his poems abound with beautiful moral sentiments and expressions, especially his ode to God, which was not only translated into several European languages, but also into Chinese and Japanese. It is said to have been hung up in the palace of the emperor of China, printed in gold letters on white satin; and, according to Golownin's account, it was placed in the same manner in the temple of Jeddo. His complete works appeared in St. Petersburg (5 vols., 1810–'15).

DESAIX DE VEYGOUX, Louis Charles Antoine, a French general, of a noble but poor family, born at the castle of Ayat in Auvergne, Aug. 17, 1768, killed at Marengo, June 14, 1800. He was gratuitously educated at the military school of Effiat, which he left at 15 to enter the regiment of Brittany under the name of the chevalier de Veygoux. His regular conduct and strict attention to duty commended him to his superiors, while his liberal opinions estranged him from the class to which he belonged, and from his family. In the beginning of the revolution he was attached to the staff of Marshal Luckner. After Aug. 10, 1792, having signed a protest against the decree by which the legislative assembly suspended the authority of the king, he was cashiered, and afterward imprisoned, but Carnot reinstated him. He served on the Rhine under Pichegru and Moreau, with such ability that he was promoted to the rank of general of division. In 1796 he seconded Moreau in his campaign through Bavaria, and in the famous retreat which won for that general the reputation of a great strategist. On the return of the army to the Rhine, Desaix defended the fort of Kehl; and notwithstanding the dilapidated condition of the place, he held it for 2 months against the repeated efforts of the archduke Charles, and finally concluded a highly honorable capitulation. The next year he again led the army across the Rhine, an op-

eration in which he showed consummate skill. In the expedition to Egypt he received the command of a division, and after the storming of Alexandria, marched to Cairo with the vanguard. He took part in the battle of the pyramids, and being ordered to pursue Murad Bey, defeated him in several encounters, and driving him into Nubia, conquered the whole of upper Egypt. Here he established a regular government, and inspired the Egyptians with such esteem that they called him the "just sultan." When Bonaparte embarked from Egypt, he placed Kleber in command of the French troops, and ordered Desaix to follow him. The latter sailed on board a Ragusan bark, but on nearing his destination was intercepted by an English frigate, and was detained a prisoner for 30 days. Being at last released, he arrived, May 3, 1800, at Toulon, and hastened to join Bonaparte in Italy, where he arrived June 11, and was put in command of a division, with orders to prevent the army which had just taken Genoa from joining that under Melas at Alessandria. He was consequently at some distance from the main army on the morning of June 14, but on hearing the artillery, he hastily returned, and arrived in time to change the nearly lost battle of Marengo to a complete victory. But he did not witness the result of his movement; he was shot through the heart as he was entering the action. Bonaparte wept for him, had a medal struck in his honor, and decreed that a statue should be erected to his memory in the *place des victoires* at Paris, and that his grave should be placed on the summit of the Alps, under the care of the monks of St. Bernard.

DÉSAUGIERS, Marc Antoine Madeleine, a French song-writer and dramatist, born at Fréjus, Nov. 17, 1772, died in Paris, Aug. 9, 1827. At the age of 17 he produced a successful one-act comedy. He was in St. Domingo, whither he had accompanied his sister, who was married to a planter, when the insurrection of the blacks broke out, from which he barely escaped with his life to the United States, where he earned a living by teaching pianoforte playing. He returned to France in 1797, and wrote songs and light comedies. Some of his plays, such as *Les petites Danaïdes*, *La chatte merveilleuse*, and *M. Vautour*, had an unprecedented run; while his songs were more popular than those of any other writer except Béranger.

DESAULT, Pierre Joseph, a French surgeon, born of humble parentage at Magny-Vernais, a village of Franche Comté, in 1744, died in Paris, June 1, 1795. He commenced his education for the church in a Jesuit school, but exhibiting a strong inclination toward the study of surgery, was permitted to acquire the rudiments of the art from the barber-surgeon of his native village, after which he was sent to the military hospital at Befort, where he remained 3 years, giving special attention to gunshot and sword wounds. While here he translated Borelli's treatise *De Motu Animalium*. In 1764 he went to Paris, and there availed himself of the facilities for dissection with such success that he was soon competent to open a course of demonstrations in anatomy. In 1776 he became a member of the college of surgery. Thereafter his progress was rapid, having successively become chief surgeon to the hospital of the college, consulting surgeon to St. Sulpice, in 1782 surgeon-major to La Charité, and finally chief surgeon to the Hôtel Dieu, with the reputation of being the most skilful operator in France. In connection with the Hôtel Dieu he instituted a clinical class which attracted many students. The chief cases that came before the class were reported in a serial, entitled *Journal de chirurgie*, edited by the pupils. In the revolution he was arrested while lecturing, May 28, 1793, and carried to the Luxembourg, from which, however, he was liberated at the end of 3 days, more from need of his professional skill than from any leniency in his accusers. Having been employed to attend the dauphin, during the imprisonment of that unfortunate youth in the temple, he bestowed on him unremitting care. Suddenly he himself was seized with illness, which almost immediately terminated in delirium and death. The rumor of the time asserted that he was poisoned, because he refused to lend himself to the murder of his patient. This supposition was favored by the coincidence that Dr. Chopart, who succeeded Desault in his attendance, died with equal suddenness, and that soon afterward the young prince was reported dead. An autopsy in the case of Desault showing no trace of poison, his death was set down to ataxic fever. The republic pensioned his widow. Desault in manner was abrupt, even to rudeness, but under this rough husk lay many kindly qualities. His pupils gave him the name of *le bourrou bienfaisant*. He introduced numerous improvements into his art, both in instruments and their use, especially in the treatment of fractures and ligature of arteries. In conjunction with his friend Chopart, he wrote the *Traité des maladies chirurgicales* (2 vols. 8vo., 1780), which has been translated into English by Trumbull.

DES BARRES, Joseph Frederic Wallet, an English soldier and hydrographer, born in 1722, died in Halifax, N. S., Oct. 24, 1824, while on his way to England. He was descended from the Protestant branch of a noble French family, which emigrated after the revocation of the edict of Nantes. He received his education under the Bernouillis, entered the royal military college at Woolwich, and was offered the choice of a commission either in the royal artillery or corps of engineers. Preferring immediate active service, he embarked in March, 1756, as lieutenant in the 60th regiment of foot, for America; where, having raised above 300 recruits in Pennsylvania and Maryland, he was ordered to form and discipline them as a corps of field artillery, which he commanded until the arrival of one of the battalions of the royal train from England. In 1757 he commanded a detachment of volunteers

against the Indians, who had committed depredations in the neighborhood of Schenectady and other frontier towns; surprised the chiefs, whom he made prisoners, and soon after gained their confidence so completely, that they not only were restrained from further acts of hostility, but became useful to the army, in which a corps of them continued to be employed to the end of the war. In 1758 he was engaged in the expedition against Louisburg, where he had the good fortune to effect a landing in a violent surf, and to take from the enemy an intrenchment by which the debarkation of the army was greatly facilitated. At this siege he was on a critical occasion ordered to the duty of an engineer, and after the capitulation he employed himself in drawing a chart on a large scale, from papers and plans obtained there, which was found very useful in the next spring, as the navigation of the river St. Lawrence was then known only to a few Canadian pilots. At the siege of Quebec he served under Wolfe as an aide-de-camp, and was making his report when that hero received his mortal wound, and fell dying in his arms. By the expenditure of lives in the campaign of 1759 and the ensuing winter, and in the unsuccessful battle fought by Gen. Murray, April 28, 1760, the army in Canada was reduced to less than 2,000 men fit for duty. The fortifications of Quebec being in a dismantled state, the preservation of what had been acquired, as well as the expectation of future conquests, seemed to rest on the operations for its actual defence. The conducting of these operations fell to Des Barres as directing engineer, and here, and subsequently in the reduction of Fort Jacques Cartier and other strong places, which completed the conquest of Canada, his endeavors proved successful. He was afterward ordered to Nova Scotia to assist Gen. Bastide in tracing designs and making estimates of the expense for fortifying the harbor of Halifax, and securing its dock yard. In 1762 he served as directing engineer and quartermaster-general in the expedition for retaking Newfoundland, and was honored with public thanks, as having essentially contributed to the recovery of that island. After making surveys of some of its principal harbors, he was ordered to repair to New York, to proceed on reconnoitring excursions and report observations on the expediency of establishing a chain of military posts throughout the British colonies. In 1763 Lord Colville received instructions to employ him on the survey of the coast of Nova Scotia, which was projected by Admiral Spry, who proposed the undertaking to senior officers prior to recommending Des Barres to the admiralty for that duty. In this work he was engaged until 1773, and on his return to England, 1774, the king expressed his commendation of the manner in which this duty had been performed. Previous to this, many of the fine harbors of Nova Scotia were known only to fishermen, and the isle of Sable was a terror to all navigators. The want of correct charts of the coast of North America for the use of the fleet engaged in carrying on the American revolutionary war, began at this time to be felt; and on Earl Howe representing the immediate necessity of their being prepared, Des Barres was selected to adapt the surveys of Holland, De Brahm, and others to nautical purposes. These he published in 1777 under the title of the "Atlantic Neptune," in 2 large folio volumes. In 1784 the government of the island of Cape Breton was conferred on him, with the military command of that and of Prince Edward's island; and soon after he commenced building the town of Sydney, and opened and worked the valuable coal fields at the entrance of the river. From his official position he was engaged in aiding and removing the royalists from the United States after the war of the revolution. In 1804 he was appointed lieutenant-governor and commander-in-chief of Prince Edward's island, in the gulf of St. Lawrence, being then in his 82d year. In person he was short, and at the age of 95 lithe and active; about which time he talked of making the tour of the United Kingdom, to which he allotted 2 years; this performed, he was to commence that of Europe, which he calculated would take 3 years more; after which it was his intention to return to his native place, and there spend the remainder of his days. He was Capt. Cook's teacher in navigation.

DESCANT, in music, an old term, now understood to be synonymous with counterpoint. It signifies strictly an unpremeditated enlargement upon a given subject, which, sung by another voice or by voices, formed the accompaniment of the descant. Musicians distinguished between plain, figurative, and double descant.

DESCARTES, René (Lat. Renatus Cartesius), a French philosopher, born in La Haye, between Tours and Poitiers, in Touraine, March 31, 1596, died in Stockholm, Feb. 11, 1650. He was the youngest son of a councillor of the parliament of Rennes, of an ancient and noble family, and early in life, when as yet a mere boy, evinced such a disposition to inquire into the nature and causes of things, that he passed under the sobriquet of the young philosopher. His education was conducted in the Jesuit college of La Flèche, where, in spite of the extreme delicacy of his physical constitution, he made rapid progress in the Greek and Latin classics, and the other ordinary studies of such an institution. He contracted also while there a friendship with Mersenne, which lasted until the end of his life; and though Mersenne became a monk, it was chiefly through him that Descartes communicated from the profound scholastic retirement which he sedulously sought with the outside learned world. After leaving college, in his 16th year, he occupied himself in acquiring the manly accomplishments of riding and fencing, with a view to the military life, to which he was destined by the wishes of his family and the spirit of the times. But his health did not allow him to enter the service immediately, and he was sent to Paris with a tutor, in order to pass two years in the further prose-

cution of his studies. In 1616 he joined the army of the prince of Orange, and while in garrison at Breda composed his *Compendium Musicæ*, which seemed a prelude to the research for harmony which he was soon about to carry into all the realms of knowledge. He was driven to it, doubtless, by the painful uncertainty and chaotic confusion which reigned in nearly all the departments of human inquiry. As a reaction against the prevailing tone, which was the despotism of authorities, many of the finest intellects had taken refuge in scepticism, so that Mersenne could write in 1623: "There are 50,000 atheists in Paris;" and the most popular verses of the *Agrippine* of Cyrano were those which sang:

Une heure après la mort, notre âme évanouie
Sera ce qu'elle était une heure avant la vie;

which may be translated:

An hour after death, our soul, released from earth,
Will be just what it was an hour before its birth.

At the same time there was a bitter reaction against the past in the scientific aspirations of those students of Italy, France, Germany, and England, who began to cast off the fetters of the scholastic logic, and to open new methods of investigation into nature, by means of observation and experiment. Descartes was torn by the doubts of his epoch, but he shared also in its grand hopes; and if he doubted, it was only to cleanse his mind of the errors of the past, and to enable it to move more freely toward the grand constructions of the future. In 1619 he left the Dutch army, and entered as a volunteer into the service of the duke of Bavaria; he was present at the battle of Prague in 1620, and made the campaign of Hungary in 1621. The atrocities which he witnessed in this war are said to have been the occasion of his resigning his commission; but the probability is that his active mind had exhausted the uses of that mode of life, and he was eager to enlarge his knowledge of men and society by more extensive travel. Quitting the profession of arms altogether, therefore, he visited the greater part of the north of Europe, then returned to France, where he sold his estates, and speedily resumed his journeys. He spent considerable time in Switzerland and Italy, being present at Rome during the jubilee of 1625, and wherever he went observing the grand phenomena of nature, and perfecting himself in the acquisition of all existing knowledge. It was at the town of Neuburg, on the Danube, where he passed the winter, that the plan of devoting the remainder of his days to the reconstruction of the principles of human knowledge, which had long been maturing in his mind, took a definite shape. While he wandered from the Baltic to the Mediterranean, he was digesting the outlines of the great discoveries in geometry and method, destined soon to change the intellectual currents of the world. He was but just 33, and in the height and vigor of his powers. Repairing first to Paris, where he moved about from one obscure house to another to escape the intrusions of friends, he next settled in the neighboring country, and being disturbed there, finally fixed his retreat in Holland, "the busy hive of labor and liberty," where he found it more easy to create the solitude necessary to his profound meditations. His life became that of an ascetic, emancipated from all social ties and relations, in order that he might devote himself the more exclusively to what was now his only wedded wife, the truth. He did not refuse, however, all participation in the affairs of the world; in 1633 he made a brief visit to England, the following year to Amsterdam; and, indeed, he constantly, through the mediation of Mersenne, maintained an active correspondence with the learned men who sought his instruction or his friendship. In 1637 he began a more open career by the publication of a volume from the press of Leyden, entitled *Discours de la méthode*, which contained treatises on method, on dioptrics, on meteors, and on geometry. The first of these, beside an admirable picture of his life and of the progress of his studies, furnished a clear outline of a new science of metaphysics only expanded in his later and larger works. In 1641 he published in Latin, from the press of Paris, his *Meditationes de Prima Philosophia*, which carried his speculations into abstruse questions as to the existence of God and the immortality of the soul. He invited criticisms of these, which, in later editions, are arranged and replied to under 7 heads, wherein he considers all the objections raised to his original system. These works filled Europe with his name, and at the close of the year 1641 he was invited to France by King Louis XIII., but he refused to quit his retirement. In 1644 his *Principia Philosophiæ* appeared, which 3 years later was translated into French by one of his friends, Claude Picot. He then went to France, where a pension of 3,000 livres a year was conferred upon him; but as Queen Christina of Sweden invited him to Stockholm, at the same time appointing him director of an academy which she proposed to establish, at a salary of 3,000 crowns a year, he was induced once more to abandon his native country. It was a fatal choice for him, for the rigors of the climate, combined with the unusually early hours exacted from him by the queen, in an eccentric wish to take lessons from him, led to his death in less than two years. He was buried at Stockholm, but 16 years afterward Louis XIV. caused his remains to be disinterred and carried to France, where he was entombed in the church of Ste. Geneviève du Mont, in the midst of magnificent ceremonies, and of the almost universal homage of his enlightened countrymen.—Descartes was an encyclopædic genius, and it would be impossible, in an article like this, to describe the entire scope and influence of his activity. He created an epoch in the history of the human mind, and can only be classed with men of the first order, like Plato, Aristotle, Bacon, Newton, and Kant. With Bacon, he was one of the founders of modern philosophy, but

he pushed his inquiries further than Bacon in many respects, and in a somewhat different sphere. What the latter accomplished for natural science, Descartes accomplished for moral and metaphysical; and it is no exaggeration which considers him as the father of that stupendous movement of intellectual investigation which has given to the world Malebranche and Spinoza, and after them the entire school of the great German idealists, beginning with Leibnitz and Wolf, and culminating in Kant and Hegel. As a metaphysician, he was the fountain head of the speculation of a whole subsequent century, while he added to his glory in that sphere the scarcely inferior distinction of a great discoverer in the mathematics, and of an earnest and sedulous laborer in nearly all the broad domains of physical science then known. Not wholly exempt from the errors of his day, he was yet immeasurably in advance of his day; while he enjoys this singular eminence among the greater number of philosophers, too much given to the jargon of learned words and abstruse phrases, that his style, his manner of expression, is as clear and beautiful as his thought is great. French style appears nowhere more simple, limpid, and direct than in the varied dissertations of Descartes, even when he treats of subjects the most recondite and difficult. Sir James Stephen compares the language of Descartes to the "atmosphere, by the intervention of which we see, though it is itself invisible. It is the nearest possible approach to that inarticulate speech in which disembodied spirits may be supposed to interchange their thoughts. It has no technical terms, no appeals to the memory, no coloring of imagination or of art, no trope or epigram or antithesis, no rhetoric and no passion; and yet it wants neither elegance nor warmth. The warmth is the warmth of a devout solicitude to attain truth and to impart it. The elegance consists in the felicity with which every word, sentence, paragraph, and discussion falls into its proper place, and exactly fulfils its appropriate office." It was owing to this admirable clearness, perhaps, as much as to the more essential merits of his system, that it was said, at the time of Descartes' death, that everybody, great or small, in England and France, who thought at all, thought Cartesianism. The fundamental principles of the philosophy of Descartes relate to his method, which takes its point of departure in universal doubt, and places the criterion of all certitude in evidence, or in other words, in reason, as the sovereign judge of the true and the false; to the erection of the individual consciousness into the fundamental ground and source of all correct philosophy—*cogito, ergo sum;* to the radical distinction which is drawn between the soul and the body, the essential attribute of the former being thought, and that of the latter, extension; to the demonstration of the existence of God from the very idea of the infinite; to the division of ideas into those which are innate, or born within us as necessary or inspired, those which are factitious, or created by us, and those which are adventitious, or come from without by means of the senses; to the definition of substance, as that which so exists as to need nothing else for its existence, and which is applicable in the highest sense only to God, who has his ground in himself, but only relatively to the thinking and corporeal substances, which need the coöperation of God to their existence; and to the affirmation that the universe depends upon the productive power, not only for its first existence, but for its continued being and operation, or in other words, that conservation is perpetual creation. Other points in this philosophy are important, and other aspects of it are to be regarded by the student; but for the popular reader these chiefly deserve attention, because these were characteristic and creative, and furnished the themes for the greater part of the agitated discussions of later years. From his theory of doubt, except upon evidence, for instance, the philosophy of the 17th century, and the whole of modern philosophy, in fact, derived that disdain for the authority which formerly fettered the free movements of the mind, and that reliance upon reason, which Arnauld, Malebranche, Pascal, Bossuet, Fénelon, and others appealed to so effectively. This vivid determination of the consciousness, or the Me, as the proper object of metaphysical investigation, was the starting point of those great systems of thought, both Scotch and German, which are such remarkable phenomena in the history of intellectual development. It is easy to trace, also, to his doctrine of substance, the vast pantheistic speculations of Spinoza, and more lately of Fichte and Hegel. In short, the schemes of Geulinex, Leibnitz, Wolf, Kant, and perhaps of Swedenborg, are all more or less directly affiliated to the great leading ideas of the French thinker. As a whole, therefore, we are not surprised to learn that when his system appeared, it produced an instant and vivid sensation. The scholastics were astonished by an assault at once so radical and so vital; the sceptics saw with stupefaction a scepticism more searching than theirs rising into the most solid religious faith; while the independent men of science, who had long been struggling against the methods of the old dialectics, received with joy and gratitude a doctrine which seemed to place their researches on an immovable foundation of truth, and to promise to crown them with the richest fruits of progress. For a while Descartes threatened to succeed to the place of absolute dictation and mastery which had been so long assigned to Aristotle. His influence passed from the oratory and the study to the popular literature; all the great writers of the age of Louis XIV. were tinctured by it; but just as it appeared to have attained a universal acceptation, it began as rapidly to fade and shrink. The reasons of this decline are to be found partly in the growth of Locke's sensational philosophy; partly in the demonstrated impotence of Descartes' principles to resolve many of the higher problems to which he aspired; but

chiefly in the discoveries of Newton and the progress of physics, which discredited his physical theories, and therefore brought his metaphysical conclusions into distrust. The theory of vortices, by which he endeavored to explain the movements of the heavenly bodies, gave place to the simpler theory of Newton as to a law of universal gravitation; but science has not ceased in consequence to confess its obligations to Descartes for his important discoveries as to the application of algebra to geometry, his contributions to dioptrics, to mechanics, and to hydrostatics, and for that fearless spirit of investigation, which, if it led him into mistakes, enabled him also to anticipate many truths ascribed to a later period.—After the death of Descartes, in addition to the works we have already mentioned, there were published: *Le monde de Descartes, ou le traité de la lumière* (12mo., Paris, 1664); *Le traité de l'homme et de la formation du fœtus* (4to., Paris, 1664); *Les lettres de René Descartes* (3 vols. 4to., 1657–'67). The principal complete editions of his writings are *Opera Omnia* (8 vols., Amsterdam, 1670–'83); *Œuvres complètes de Descartes* (9 vols., Paris, 1724); *Œuvres complètes de Descartes*, by Victor Cousin (11 vols., 1824–'26), which is perhaps the most perfect edition; *Œuvres philosophiques de Descartes* (1835), by Garnier, who added a life, and a thorough analysis of all his writings. On the philosophy of this master, the dissertations are almost without number, but the few most useful or curious are comprised in the following list: *Recueil de pièces curieuses concernant la philosophie de Descartes* (Amsterdam, 1684, published by Bayle); *Mémoires pour servir à l'histoire du Cartésianisme*, by Huet (Paris, 1693); *Mémoires sur la persécution du Cartésianisme*, by Cousin (Paris, 1838); *Histoire et critique de la révolution Cartésienne*, by M. Francisque Boullier (2 vols., Paris, 1842); *Le Cartésianisme, ou la véritable rénovation des sciences*, by M. Bordan Demoulin (2 vols., Paris, 1843). Of late years the study of Descartes has revived among the French philosophers. See Damiron's *Essai sur l'histoire de la philosophie en France au XIX^e^ siècle*, which contains a report in 6 memoirs read to the academy, on the philosophy of Descartes and its effects.

DESCENT, in law, is the transmission of an estate in lands by operation of law, upon the decease of a proprietor, without any disposition thereof having been made by him. The term is derived from a principle existing until very recently in the English law, that an inheritance could never lineally ascend, yet upon failure of lineal descendants, it could ascend collaterally. Thus the father could not be the heir of his son, but the uncle could inherit from the nephew. There was therefore an inaptness in the expression even as used in the common law doctrine of inheritance, and still greater incongruity in American law, which allows a lineal ascent from the son to the father. Succession is the more appropriate phrase in the Roman law, and from that adopted in the French and other modern systems of law. Gibbon has well remarked that the Roman law of hereditary succession "deviated less from the equality of nature than the Jewish, Athenian, or English institutions." The oldest son of a Hebrew inherited a double portion. By the Athenian law the sons inherited jointly, but the daughters were wholly dependent upon what provision their brothers might choose to give them by way of marriage portion. The English law of primogeniture gives, not a larger proportion, but the whole, to the eldest son; and in various other respects which will be presently referred to, the natural order of equity is singularly disregarded in the law of descent. On the other hand, by the Roman law, when a man died intestate, all his children, both sons and daughters, inherited alike; and in case of the decease of either, the descendants of the decedent would take such share as would have belonged to him or her. The distinction of agnates and cognates was indeed introduced at an early period, whereby the descendants of females, who were called cognates, were excluded; but by imperial constitutions they were restored to the right of succession, with a diminution of a third in favor of the agnates, that is, descendants of males, and even this discrimination was abrogated by Justinian. On failure of lineal descendants, the father and mother or other lineal ascendants were admitted. Such was the rule as to lineal succession. In respect to collateral inheritance, by the law of the 12 tables, agnates, whether male or female, were admitted alike, but by the later law all females of collateral kindred were excluded; the hardship of the rule was in some measure relieved by the prætor, who gave to females thus excluded a share of the personal estate. Justinian restored the right of succession as it had originally existed. Descendants of females of the collateral kindred were still, however, left unprovided for. Thus, though a sister could inherit from her brother, yet her children could not; but the reverse of the rule did not hold, for there was no corresponding disability in the brother to inherit from the children of his sister. The rule of collateral succession was that the nearest agnate (or all the agnates of the same degree) took the whole estate. The mode of estimating the degree of consanguinity was by the Roman law to take the entire number of intermediate persons in the ascending and descending scale between the parties whose relationship was in question. Thus, first cousins would be related in the fourth degree, being each two removes from the common ancestor; whereas by the canon law, which has been taken as the basis of the English rule of descent, the consanguinity is measured by the number of degrees between the most remote of the two persons and the common ancestor, which in the case of cousins would be two degrees; and it would be the same between uncle and nephew. The rules of descent by the common

law of England are exceedingly artificial, being derived chiefly from the old feudal system, and by usage become fixed, though the reasons that first gave rise to them have long ceased to exist. The principal of these rules are as follows: 1. The estate descends lineally to the oldest son, to the exclusion of all others; or if he is deceased, then to his descendants, male or female, following the same rule of preference in all respects as prescribed in this and the following rules. 2. In case of the decease of the oldest son without issue, then to the next oldest and his descendants, and so to the last of the males. 3. In case of failure of male issue, then to the daughters, who, contrary to the order prescribed in the preceding rules, do not take successively, but become seized jointly of a peculiar estate called coparcenery, the incidents of which we need not now stop to discuss, further than to say that each coparcener has an absolute undivided interest, which she may convey, or which on her decease will descend to her heirs. 4. Failing all lineal descendants, the estate does not ascend lineally—that is to say, to the father or grandfather, who by the common law are incapacitated to take directly from the son or grandson, though they may indirectly through collateral heirs—but to the nearest collateral kindred, still following the preference of males to females, and, of the males of the same degree, the oldest having the exclusive right. Thus the oldest brother and his descendants will take; failing whom, the next brother and his descendants; or in default of brothers, then all the sisters in copercenery; but if there be no brothers or sisters, then the kindred of next degree will succeed, subject to the same rules of preference. 5. In respect to collateral succession, several other rules apply. (*a.*) The heir must be not only the nearest of kin of the person last seized, but must be of the whole blood, that is to say, must be descended from the same two ancestors, male and female; as, if A and B are brothers having the same father but not the same mother, if an estate descends to A from the father and he dies, B shall not inherit from him, although if A had died before the father, B would have been the heir of the father. So far was this exclusion carried by the common law, that a sister of the whole blood would take in preference to a brother of the half blood, and the estate would even escheat rather than it should descend to the latter; and the same rule prevailed in respect to more remote collateral relatives. (*b.*) It is also necessary, in order to inherit collaterally, to be of the blood of the first purchaser, that is to say, of the person who first acquired the estate; as, if A purchase land and it descends through several generations to B, who dies without issue, no collateral relative of B can take the estate unless he is also of the blood of A, from whom it originally came. (*c.*) Kindred on the side of male ancestors, however remote, are preferred to kindred descended from females, however near, unless the estate descended from a female, in which case the kindred of such female can alone inherit. Thus the relatives on the father's side are preferred to the mother's, and on the grandfather's to the grandmother's, and so in all the degrees of ancestry. (*d.*) In computing degrees of consanguinity, the rule of the canon law is adopted as before mentioned, whereby the relationship to the common ancestor is alone considered. According to this rule, brothers are related in the first degree, cousins in the second; but as this would often make a different degree of relationship between the same parties, according as it was computed from one or the other to the common ancestor, it was found necessary to adopt a further rule, that the consanguinity of each to the other was to be determined by that of the most remote from the common ancestor. Again, there might sometimes be different sets of kindred in the same degree of relationship by referring to different ancestors, as a nephew is in the same degree as an uncle, the common ancestor of the one being the father, of the other the grandfather; in such a case, another rule intervenes, viz.: that the relative representing the nearest ancestor shall take priority, according to which the nephew would inherit before the uncle. Several important changes have been made in the law of descent by statute 3 and 4 William IV., c. 106 (1833), the principal of which are: 1, that a lineal ancestor is permitted to inherit, and takes precedence of a collateral heir; thus the father is preferred to the brother or sister; 2, relatives of the half blood are relieved from disability to inherit, and succeed next after relatives of the same degree of the whole blood; 3, several provisions are made for the determination of the question who was the purchaser from whom by the rules of common law the descent was to be traced. The person last entitled is to be deemed a purchaser, unless it be shown that he took by inheritance, and so of any preceding ancestor. In the case of a devise by a man to his heir, such heir shall be deemed to have taken by the devise and not by descent, and is to be regarded as a purchaser. When land is purchased under a limitation to the heirs of a particular ancestor, such ancestor is deemed the purchaser. From this summary of the English law of descent, which gives only the general rules without noticing certain exceptions which are said to exist by ancient usage in some places, it is apparent that the basis of the system was a condition of society no longer existing. The theory of seeking for a single male heir to the exclusion of all others belongs to the turbulent period when a military head of a family was needed, and all the other members of the family found shelter in a common mansion, under the protection of an organized domestic force. The perpetuation of the rule, in a period of private immunity from violence, can serve no other purpose than to keep together the estates of great land proprietors. This may be essential for maintaining the respectability of the titles of nobility, but is inapplica-

ble to all other proprietors; and moreover, personal property, which was comparatively unnoticed by the feudal law, but which has become a large proportion of the wealth of the kingdom, is distributed by another rule, conforming to the equitable principle of the civil law. The retention of this part of the old feudal law is therefore mainly attributable to the stern prejudice in favor of ancient usage which has always been peculiar to the English people.—The law of descent in the United States is based upon the English statute (22 and 23 Charles II.) for the distribution of the personal estate of intestates, which statute is substantially in conformity with the civil law. In most of the states real and personal estate descend by the same rule, with the exception only of the interest of the husband and wife respectively, the former of whom has an estate for life in all the lands belonging to a deceased wife, and the wife has an estate for life in one third of the lands belonging to a deceased husband, which is called dower. The rule of descent in the state of New York, which may be taken as the law of most of the other states, is: 1, of the lineal descendants of the intestate, an equal proportion to all who are of equal degree of consanguinity, whether male or female; but in the case of the decease of any one of them, then his or her descendants take the proportion that would have belonged to such deceased party if living; thus, should the intestate leave 2 children and 3 grandchildren, descendants of a deceased child, the estate will be divided into 3 parts, the 3 grandchildren taking the $\frac{1}{3}$ which would have belonged to the parent whom they represent; 2, upon failure of lineal descendants, the father of the intestate will inherit, unless the estate came on the part of the mother; 3, if the father is not living, or cannot for the reason above mentioned take the estate, the mother will be entitled to hold it for life, the reversion to belong to the brothers and sisters; 4, if no lineal descendants or father or mother, then the estate will descend to the nearest collateral relatives of equal degree, and the same rule applies as in the case of lineal descendants, that the descendants of a deceased party take the same share that such ancestor would have been entitled to if living. The rules as to collateral succession are as follows: (*a*) brothers and sisters, or the children of deceased brothers and sisters, are first entitled; but in case no brother or sister is living, but there are descendants of several, then such descendants take equally *per capita*, and not *per stirpes* or representation, as would be the case if one of the brothers or sisters were living; (*b*) if no brothers or sisters of the intestate nor descendants of deceased brothers or sisters, the next heirs are uncles and aunts on the father's side, or failing these, the same relatives on the mother's side; if, however, the estate came on the part of the mother, then her relatives have the preference; but if the estate had not descended from either father or mother, then the relatives on the part of both take equally. In the descent, both lineal and collateral, relatives of the half blood are equally entitled with those of the whole blood. The rules of succession by the French civil code are nearly the same as those prevailing in this country. The variations are principally these: 1, if there are father and mother (or either of them) and brothers and sisters, the estate is divided into 2 parts, one of which belongs to the father and mother in equal proportion, the other to the brothers and sisters or descendants of a deceased brother and sister, such descendants taking by representation the share that the child whom they represent would have taken; if either father or mother is deceased, his or her share vests in the brothers and sisters; 2, if there is a father or mother, but no brothers or sisters, the collateral relatives take a half; 3, if there are children of different father or mother, the estate is divided into 2 parts, the paternal line taking one part and the maternal or uterine the other; children of the whole blood take a share in each moiety.

DESERET, a co. of Utah, bounded E. by Great Salt Lake, and W. by California. It is drained by the Mary or Humboldt river, and traversed by several mountain ranges.—The name of Deseret was also given by the Mormons to the territory around the Great Salt lake, but was not accepted by congress, who substituted therefor the name of Utah. According to the Mormons, "Deseret" signifies "the land of the honey bee."

DESERTER, in military affairs, an officer, soldier, or sailor who abandons the public service in the army or navy, without leave. In England the punishment for desertion is, with certain limitations, left to the discretion of court martials, death being the extreme penalty. By the articles for the government of the navy of the United States (art. 12), it is enacted that "if any person in the navy shall desert to an enemy or rebel, he shall suffer death," and (art. 13) "if any person in the navy shall desert in time of war, he shall suffer death, or such other punishment as a court martial shall adjudge." The rules and articles for the government of the land forces of the United States authorize the infliction of corporal punishment not exceeding 50 lashes for desertion in time of peace, by sentence of a general court martial; and the laws do not permit punishment by stripes and lashes for any other crime in the land service. In time of war a court martial may sentence a deserter to suffer death, or otherwise punish at its discretion.

DESÈZE, Raymond, a French magistrate, born in Bordeaux in 1750, died in Paris in 1828. A lawyer in his native city, he was called to Paris by the count De Vergennes, gained reputation in several important lawsuits, was chosen one of the counsel of King Louis XVI. when arraigned before the convention, and delivered an eloquent defence in his behalf. He was arrested, but liberated after the 9th Thermidor, lived in retirement during the consulate and the

empire, and on the restoration of the Bourbons was appointed president of the court of cassation.

DESFONTAINES, Pierre François Guyot, a French critic, born at Rouen in 1685, died Dec. 16, 1745. He studied under the Jesuits, received orders, and was a successful teacher of rhetoric in the college of Bourges. He was invited to Paris in 1724, to restore the *Journal des savants*, which had fallen into discredit. In this he succeeded, and published afterward, sometimes alone, and sometimes in conjunction with others, several periodicals, among which were the *Observations sur les écrits nouveaux*. His criticisms were marked by severity and rudeness, and among the many enemies whom he made by his trenchant pen was Voltaire, who had once saved him from prison, or perhaps the galleys. The paper warfare between the critic and the philosopher attracted general attention, and ended in the discomfiture of the former. The principal works of Desfontaines are a *Dictionnaire néologique*, and a translation of the Æneid.

DESFONTAINES, René Louiche, a French botanist, born in Tremblay, in Brittany, in 1752, died in Paris, Nov. 16, 1833. After studying at the college of Rennes, he went to Paris to prepare for the medical profession, but devoted himself chiefly to botany. He was received into the academy of sciences in 1782, the custom of the time being to admit young men of approved capacity, with a view of encouraging them to greater accomplishments. He immediately embarked for the Barbary states, and during two years explored the natural history, especially the flora, of the north of Africa. He published the result of his investigations in the *Flora Atlantica* (2 vols., Paris, 1798), which gave descriptions of 1,600 species of plants, 300 of which were new. On his return to Paris in 1785 he was appointed by Buffon to succeed Lemonnier as professor in the *jardin des plantes*, and from this time he was occupied with his lectures. He was the first to indicate the difference in growth and structure between the monocotyledonous and the dicotyledonous plants. He made a catalogue of the *jardin des plantes* (1804; 3d ed. in Latin, 1829); continued the *Collection des velins du muséum d'histoire naturelle*, which had been begun for Gaston of Orleans; and published numerous memoirs in the transactions of learned societies.

DESHA, a S. E. co. of Ark., bordering on the Mississippi, intersected by Arkansas and White rivers; area, 869 sq. m.; pop. in 1854, 3,971, of whom 1,840 were slaves. The surface is low, level, and subject to inundation. The soil is alluvial, and in 1854 produced 6,940 bales of cotton, and 130,055 bushels of corn. Number of pupils in the public schools, 40. Capital, Napoleon.

DESIRADE, or Deseada, a rocky island of the Little Antilles, in the Caribbean sea, E. of Guadeloupe, of which it is a dependency. It is scantily furnished with wood and fresh water. Area, 10,695 acres; pop. in 1856, 1,235, of whom 284 were whites. It was the first island discovered by Columbus in his second voyage, on which he set out, Sept. 25, 1493.

DESHOULIÈRES, Antoinette (du Ligier de la Garde), a French authoress, born in Paris about 1634, died in the same city, Feb. 17, 1694. The daughter of a *maître d'hôtel* of Marie de' Medici and Anne of Austria, she was early noted for beauty and wit, and received a brilliant education under the best masters. She studied the Latin, Italian, and Spanish languages; read the long romances of D'Urfé, La Calprenède, and Mlle. de Scudéry, which were then the delight of the court; and early began to write verses, her first attempts being corrected by the poet Hesnaut. In her 18th year she was married to Guillaume de la Fon de Boisguérin (seigneur des Houlières), who in the troubles of the Fronde embraced the party of the prince of Condé, and was exiled. Mme. Deshoulières subsequently rejoined her husband at the court of Brussels, where she became an object of suspicion, and was imprisoned in 1657 in the castle of Vilworde, where she read the Scriptures and fathers of the church, was rescued by her husband by a *coup de main* after 8 months, and on her return to France after the amnesty became a favorite at the court of Anne of Austria. She wrote poems in almost all styles from the madrigal to tragedy, and was intimate with the two Corneilles, with Fléchier, Mascaron, Quinault, Benserade, and Ménage, and with the dukes of Montausier, La Rochefoucauld, Nevers, and Saint Aignan. She attained the best success in pastorals and in moral and philosophical pieces. Her idyls, especially those entitled *Les moutons* and *Les fleurs*, were most admired, and gained her the appellation of the 10th muse and the French Calliope; and the subsequent ill success of her tragedies caused the advice, of proverbial fame, to be given her, *de retourner à ses moutons*. She became a member of the academy of the *Ricovrati* of Padua in 1684, and of the academy of Arles in 1689. Like Mme. de Sévigné, she belonged to the literary clique hostile to Racine. Voltaire said that of all French ladies who had cultivated poetry, Mme. Deshoulières had succeeded best, since more of her verses than those of any other were known by heart. The principal editions of her works are those of 1747 and 1799, each in 2 vols.

DESMIDIEÆ, minute and interesting algæ, which grow in fresh water, and whose contour and forms present singularly beautiful appearances under the microscope. For a long time claimed both as animals and plants, they seem to stand on the limits of either kingdom. The controversy as to their true place has enlisted a great number of observers, who have submitted every fact connected with their study to the most rigorous examination. Ehrenberg has claimed them as animalcules; and in the "Annals of Natural History" (London, 1840), Mr. Dalrymple has given extended observations of a similar character upon a single genus (*closterium*), which appeared to him to indicate

animality. In the "American Journal of Science and Arts" (vol. xli., 1841), Professor Bailey admits the general correctness of Mr. Dalrymple's observations, yet differs from him in some respects. He considers the desmidieæ as animalcules, and includes them in his sketch of the infusoria. In a memoir "On the Organization of the Polygastric Infusoria," in Weigmann's *Archiv* for 1846, C. Eckhard advocates their animality. He notices only the *closteria*, and derives his argument for their being animals partly from their motion, partly from their organization. According to Pritchard, in his "History of Infusoria, living and fossil" (London, 1842), Dr. Meyen shows that Ehrenberg has described and represented in his great work a very considerable number of organized bodies looked upon by botanists as belonging to the vegetable kingdom. In these representations naturalists have been able to attain what has been long desirable; for although in respect to the more highly developed and complete vegetable beings the truest delineations are indispensably necessary at the present day, it is much more requisite that every one of these lower and microscopic organisms should be laid before us in the same tangible manner. Ehrenberg has not only given systematic descriptions of these questionable animals or plants, but his own observations, coupled with those of his predecessors, upon the nature of these bodies, will be found copiously detailed by him. It is, however, apparent that all the facts known upon the subject are interpreted as if these creations were undoubtedly animals, while the same facts would bear a very different signification if we proceeded upon the supposition that they were merely plants. Meyen contended for the vegetable character of the desmidieæ, and was the first to detect the presence of starch in the cells; and the accuracy of his remarks, which had been doubted, was fully confirmed by Ralfs, Jenner, and other recent algologists. The presence of starch in the desmidieæ can be readily detected by treating them with a solution of iodine; all vegetable tissues in which starch grains are found assume a purplish or violet color on its application. Prof. Bailey did not consider this a conclusive proof of their vegetable nature, since, if animal, the starch might have been swallowed. But it is affirmed that no starch is to be detected in the young cell, while upon the growth of the sporangium or seed-vessel it appears and increases rapidly, as in the seeds of the higher plants, in which it generally abounds. Of all the circumstances which indicate the vegetable nature of the desmidieæ, this is the most important, since it can be so easily submitted to experiment. In certain cavities in *closterium*, Mr. Dalrymple noticed a peculiar motion of molecules on which he laid some stress. This motion has been frequently noticed, and is to be seen in many plants. At first sight it would seem to denote an animal function, yet really in the desmidieæ it becomes a proof of their vegetability. It has been termed swarming, on account of the commotion which arises within the cell, as if all its contents were endowed with life; as the disturbance increases, the cell opens, when the molecules, or rather zoospores, hasten from their prison, darting about in every direction, until at length they settle down into a state of repose. The presence and functions of zoospores in plants of entirely differing families and groups, render their occurrence in those under consideration no evidence of their being animals. That the desmidieæ resist decomposition, exhale oxygen on exposure to the sun, preserve the purity of the water containing them, and when burned do not emit the peculiar odor usually so characteristic of animal combustion, are also important facts respecting this family. Berkeley, in his "Introduction to Cryptogamic Botany," remarks that much controversy has existed with respect to their true nature, but that at the present day few persons will adopt the views of Ehrenberg; for if in some points there be anomalies, as in *closterium*, their whole history is so evidently vegetable, their mode of increase, growth, &c., that if we refuse them the title of vegetables, we may as well dispute that of the whole tribe of zoosporous algæ. As to their occasionally producing bodies endowed with active motion, it is now a matter of certainty that such bodies exist in a variety of algæ of very different construction; and in order that the cellulose (or peculiar material of the cell walls of vegetables) should exhibit the proper reaction when acids are applied for tests, the membranes of cells or of the fronds must be thoroughly cleansed from all extraneous matters. But perhaps the most important of all is the fact that, under the influence of light, they give out oxygen, which, added to the other characteristics, is quite convincing.—Considering the desmidieæ as vegetable productions, we find them peculiar for their beauty, variety of forms, and the external markings and appendages to be noticed upon them. They are mostly of an herbaceous green color, and contain a green internal matter. The frond divides into two valves or segments, by a sort of voluntary action; a mode of growth in the bisection of cells that Meyen and others have proved to be frequent if not universal in the more simple algæ. In the desmidieæ the multiplication of the cells by repeated division is full of interest, both on account of the remarkable manner in which it takes place, and because it unfolds the process of cell-growth in the tissue of other plants, thus furnishing valuable facts in general vegetable physiology. The compressed and deeply constricted cells of *eriastrum* offer most favorable opportunities for ascertaining the manner of this division; for although the frond is really a single cell, yet this cell in all its stages appears like two, the segments being always distinct, even from the commencement. As the connecting portion is so small, and necessarily produces the new segments, which cannot arise from a broader base than its opening, these are at first very minute, though they rapidly increase in size. The

segments are separated by the elongation of the connecting tube, which is converted into two roundish hyaline lobules. These lobules increase in size, acquire color, and gradually put on the appearance of the older portions. Of course, as they increase, the original segments are pushed further asunder, and at length are disconnected, each taking with it a new segment to supply the place of that from which it has separated. All the desmidieæ are gelatinous. In some the mucus is condensed into a distinct and well defined hyaline sheath or covering; in others it is more attenuated, and the fact that it forms a covering is discerned only from its preventing the contact of the colored cells. In general, its quantity is merely sufficient to hold the fronds together in a kind of filmy cloud, which is dispersed by the slightest touch. When they are left exposed by the evaporation of the water, this mucus becomes denser, and is apparently secreted in larger quantities to protect them from the effects of drought. Their normal mode of propagation seems to be by the production of single large spores or sporangiums, which derive their existence from the union of the green coloring matter (endochromes) of two contiguous plants. These spores are mostly globular, although they exhibit a great variety of forms with reference to their external surfaces. Sometimes they bear no resemblance to the parent plant. But once formed, they are propagated by division, in the same manner as the ordinary cells, and in the 3d generation acquire their regular form, which they may continue to propagate for years, without ever producing a true spore.—Very little is known respecting the uses of the desmidieæ. Probably they assist in preserving the purity of the water in which they grow; a function which they may fulfil in the economy of nature in common with most aquatic vegetables. The food of bivalve mollusks belonging to fresh waters seems to be made up of them. They are found principally where there is some admixture of peat, and in clear pools rather than in running streams. They abound in open places, and are rarely seen in shady woods or in deep ditches. According to Brébisson, the calcareous districts of France are very unproductive of them. So numerous are the species and so diversified their shapes and characters, that they have been divided into distinct genera as natural series present themselves in turn. In the first of these series we discover the plant an elongated, jointed filament, which may be cylindrical, sub-cylindrical, triangular or quadrangular, plane with the margins even and smooth, or with the margins incised and sinuated. In *hyalotheca* we have the mucous envelope alluded to above, within which are numerous joints, which are usually broader than long; and as each has a shallow groove passing round it, it resembles a small pulley wheel. The minuteness of the plant may be estimated from the length of these joints, which vary from $\frac{1}{2103}$ to $\frac{1}{1351}$ of an inch. *H. dissiliens* (Bréb.) is found in North America as well as in Europe. In *desmidium*, the joints are bidentate at the angles; the filament is fragile and of a pale green color; the length of the joint is from $\frac{1}{2000}$ to $\frac{1}{7000}$ of an inch. *D. Swartzii* (Ag.) is common throughout the United States. In *micrasterias* we have a simple, lenticular frond, deeply divided into two-lobed segments, each lobe inciso-dentate and generally radiate. Many species of this beautiful plant are common in this country. We have also found *euastrum*, which belongs to the same series, of frequent occurrence. Certain curious spiny objects detected in a fossil state in flint in Europe remind us of *xanthidium*, but which probably are spores; the compressed bipartite and bivalved frond of the *xanthidium* being represented in the fossils by one that is globose and entire. The constriction about the middle of the frond is lost in *closterium*, which also differs in shape, it being crescent-like or arcuate. The species of this are common and numerous. The fronds of *ankistrodesmus* are aggregated into fagot-like bundles. *Pediastrum tetras*, occurring from Maine to Virginia, according to Bailey, has an extremely minute frond composed of 4 cells, which make a star-like figure; while *P. biradiatum*, found in New Jersey (Bailey) as well as in Germany (Meyen), has many more cells, yet still arranged in a stello-radiate manner.—In collecting the desmidieæ, the student must seek in proper situations the sediment observable in the form of a dirty cloud or greenish scum upon the stems and leaves of filiform aquatic plants. This is to be carefully transferred to a bottle of pure water, and thus he will secure many beautiful species for his microscopes. If the bottle be exposed to the light, the little plants will continue in good condition, and thrive for several months, thus furnishing subjects for examination ready at hand.

DES MOINES, a S. E. co. of Iowa, bordering on Ill., washed by the Mississippi on the E. and S. E., bounded S. W. by Skunk river, and drained by Flint creek; area, 408 sq. m.; pop. in 1856, 20,198. Limestone and anthracite are the principal mineral productions. The surface is much diversified and occupied by prairies and tracts of timber. The soil is fertile, well cultivated, and in 1856 yielded 11,274 tons of hay, 221,109 bushels of wheat, 359,938 of oats, 1,456,491 of corn, 206,026 lbs. of butter, and 20,056 of wool. Capital, Burlington.

DES MOINES, the largest river of Iowa. It rises in the S. W. part of Minnesota, and takes a S. E. course to Emmet co., Iowa. Thence it runs nearly S. S. E. to the Mississippi, which it joins about 4 m. below Keokuk. The country through which it flows is an undulating, fertile region, interspersed with tracts of prairie. The state government has recently undertaken to render the river navigable as far as Fort Des Moines, a distance of over 200 m.

DESMOND, Earls of, an ancient family of great influence in the S. W. of Ireland, from the year 1329 to 1583. The line numbered 15 earls. The title and family are now extinct.

Before the English gained a footing in Ireland, the kingdom of Cork was a separate sovereignty, embracing much of the present province of Munster. It was divided into Desmond, or South Munster, Muskerry, or West Munster, and Carbery, on the S. W. In 1172 Dermod Mac Carthy, king of Cork, with the view of aggrandizing himself by the aid of so powerful an ally, swore fealty to Henry II., but soon afterward broke his plight and attacked his liege's forces. He was overpowered, and Henry, in 1177, bestowed the kingdom on Robert Fitz Stephen and Milo de Cogan. Cogan's share, falling ultimately to co-heiresses, was divided between Robert Carew, Patrick Courcey, and Maurice Fitz Thomas. The last was created by the English monarch 1st earl of Desmond in 1329. By aggressions on the lands of Courcey and Carew, and by other acquisitions, the estates of the Desmonds so increased that the 8th earl was possessor of almost the whole of the former kingdom of Cork. This earl exercised rights of sovereignty with such a high hand that he was attainted of treason, and beheaded at Drogheda, Feb. 15, 1467. His estates, being suffered to remain in his family, continued to augment until Gerald, the last earl, owned a territory extending 150 miles through the counties of Waterford, Cork, Kerry, and Limerick, and comprising 500,000 acres of tenants' land. These earls never yielded more than a nominal allegiance to the English crown. One of them in the reign of Henry VIII. agreed with Francis I. of France that he would take up arms when required, and not lay them down till he had conquered one half of Ireland for himself and the remainder for Richard de la Pole, the representative of the house of York. Francis withdrew from the agreement, leaving the earl to explain it to his sovereign as he best might. The country of the Desmonds was Irish in language, habits, and religion. Hence it was deemed a favorable locality by Philip II. of Spain, in the days of Queen Elizabeth, to attempt the conquest of Ireland. Accordingly, on July 1, 1578, a body of Italian troops, under the command of James Fitz Maurice, brother of the earl of Desmond, and accompanied by Saunders, the pope's legate, landed in the Desmond country, where they were immediately joined by Sir John of Desmond and James Fitzgerald, other brothers of the earl. At first Earl Desmond made some show of resistance, but subsided at length into neutrality. On this, Lord Justice Pelham summoned him to surrender his castles to the queen. Desmond refused, whereon he and all of his name were proclaimed traitors, Nov. 1, 1579. Desmond now raised the standard of revolt, summoned his people to meet him at Ballyhowra, Cork, to support the Catholic cause, and his dependants responded to the call. He seized on the town of Youghal, and until Nov. 1583, maintained a determined warfare. Being by that time driven from his strongholds, one after another, he was compelled to seek safety in concealment. He wandered over the country for months, and was at last killed by a peasant named Kelly, in a cabin where he had taken shelter. His estates were divided among the captains of Elizabeth's army. Sir Walter Raleigh received 20,000 acres, which he sold cheaply to Richard Boyle, afterward earl of Cork.—Jeanne Fitzgerald, wife of James, 14th earl, lived to an age exceeding 140 years. Her husband presented her at the court of Edward IV., where she danced with the duke of Gloucestor, afterward Richard III.; she was widowed during the reign of Edward IV., and died in the reign of James I., some time after 1603. At the age of 140 she travelled from her home at Inchiquin, Ireland, by the way of Bristol, to London, to urge some claim against the government. At that time she was quite vivacious and in possession of all her faculties. Sir Walter Raleigh says: "I myself knew her." ("History of the World," book i., cap. 5.) Bacon mentions that the old countess of Desmond had thrice renewed her teeth.

DESMOULINS, Benoît Camille, a French revolutionist, born at Guise in Picardy in 1762, guillotined in Paris, April 5, 1794. He was a lawyer in Paris when the revolution broke out; he ardently adopted its principles, and became one of the favorite orators of the crowd which gathered at the palais royal to hear the news of the day. On the dismissal of Necker, July 12, 1789, he mounted a table and in an impassioned speech called the people to the defence of their threatened liberty; he boldly declared that he would not be deterred from speaking by fear of the police, and with a loaded pistol in each hand, swore that he would not be taken alive. He advised the patriots to wear a green badge as a rallying sign, and as there was not a sufficient quantity of ribbon, he gave them the green leaves of the trees in the garden. The cry "To arms!" was raised; the crowd seized upon all the arms they could find at the gunsmiths', and forming in procession, carried through the streets the bust of the dismissed minister in conjunction with that of the then popular duke of Orleans. The next day the muskets and cannon at the Invalides fell into the hands of the people, and on July 14 the Bastile was taken. Camille, who had given the first, if not the controlling impulse to this insurrection, figured conspicuously among the combatants, and at once gained popularity as one of the most influential democratic leaders. His popularity was enhanced by a pamphlet, *La lanterne aux Parisiens*, in which he styled himself the "attorney-general of the lamp-post." The success of this publication encouraged him to commence, under the title of *Les révolutions de France et de Brabant*, a newspaper which commanded a large sale and exercised great influence by its vigor of thought, sparkling wit, and lively style. Such was the importance of this periodical, that Mirabeau sought to conciliate its editor, whom he soon treated as a friend, and whose support was not useless to the great tribune. Camille had been a schoolmate of Robes-

pierre, and lived on intimate terms with the future dictator of the revolution, who was then but an obscure member of the constituent assembly. He was also acquainted with Marat, the epileptic editor of *L'Ami du peuple;* but his bosom friend was Danton, whose energetic character entirely controlled the somewhat wavering mind of the young and brilliant writer. The destinies of both were closely connected from the establishment of the club of the Cordeliers. Camille was instrumental in the insurrection of Aug. 10, 1792, and was appointed secretary to the ministry of justice when Danton received that office from the legislative assembly. He must have had a share in the massacre of September, but he used his influence to preserve the lives of several intended victims. With Danton, he was elected to the national convention, and acted and voted in accordance with his friend's directions. In the contest between the Girondists and the Montagnards, he contributed to bring the former into distrust and contempt by his *Histoire des Brissotins*, a pamphlet in which ridicule was skillfully blended with serious charges. Satisfied with their fall as a party, he would have saved them individually, but this was beyond his power. Both he and Danton now tried to bring the convention to a milder policy, and Camille established a journal toward the end of Jan. 1794, *Le vieux Cordelier*, in which he advocated conciliatory measures with as much earnestness as he had urged a contrary course in his former publication. His eloquent pen shone to advantage in the cause of justice and mercy. Denouncing the system of proscription, he demanded the establishment of a committee of clemency as a preliminary step to clearing the prisons of the suspected. This generous effort, which he supported by biting satires against the Montagnards, was answered by accusations brought against him in the club of the Jacobins. Robespierre, with hypocritical generosity toward an old friend, defended him on two occasions; he represented Camille as a wayward child, whose person it was not necessary to injure, but demanded that his writings should be burned. "To burn is not to answer," exclaimed the headlong journalist; and from that day his fate was sealed. He was arrested on the same night with Danton, arraigned with him before the revolutionary tribunal, sentenced to death, and with him sent to the scaffold. On his way there, while Danton stood composed and immovable, Camille became almost frantic, struggling with his bonds, and appealing to the people. His friend vainly motioned him to keep quiet; he continued to address the crowd, and recalled to their memory all that he had done in their service. "Behold," he cried in despair, "behold the recompense reserved to the first apostle of the revolution!" His young and beautiful wife, who had vainly implored his pardon from the old friendship of Robespierre, tried to raise a riot to save him, but she was arrested, and suffered death a few days later. Camille Desmoulins holds a distinguished rank among French pamphleteers. His *Vieux Cordelier* was reprinted in 1833.

DESNA, a large river of Russia, which rises in the government of Smolensk, flows through those of Orel and Tchernigov, and falls into the Dnieper a few miles above Kiev. It is a fine stream, abounding in fish, and navigable for the greater part of its course of 600 m. It has been proposed to open a water communication between the Caspian and the Black and Baltic seas by means of a canal connecting this river with the river Oka.

DESNOYERS, Auguste Gaspard Louis Boucher, baron, a French engraver, born in Paris, Dec. 20, 1779, died there, Feb. 15, 1857. At the age of 20 he received a prize of $400 for an engraving of Venus disarming Cupid, and in 1801 established his reputation by the reproduction of Raphael's *Belle jardinière*, in the gallery of the Luxembourg. His most admired productions are copies of that great master's works, and prominent among them is an engraving of the "Transfiguration." He was elected a member of the institute in 1816, appointed chief engraver to the king in 1825, created baron in 1828, and officer of the legion of honor in 1835.

DE SOTO. I. A N. W. co. of Miss., bordering on Tenn., and bounded N. W. by the Mississippi river; area, 960 sq. m.; pop. in 1850, 19,042, of whom 9,553 were slaves. The surface is generally level, and occupied chiefly by cotton plantations. There are extensive swamps in the western part. The soil is fertile, and in 1850 produced 20,278 bales of cotton, 741,519 bushels of corn, 10,272 lbs. of rice, and 32,907 of beeswax and honey. There were 22 churches, and 416 pupils attending public schools. The county was organized in 1836. Capital, Hernando. II. A N. W. parish of Louisiana, bordering on Texas, drained by Red and Sabine rivers; area, 910 sq. m.; pop. in 1855, 9,703, of whom 5,939 were slaves. By means of Red river it has steamboat communication with New Orleans. In 1855 the productions were 9,361 bales of cotton, and 340,034 bushels of Indian corn. Capital, Mansfield.

DE SOTO, Fernando, a Spanish officer, the discoverer of the Mississippi, born at Xeres de los Caballeros, in Estremadura, in 1500, died on the banks of the Mississippi, June 5, 1542. Of a noble but reduced family, he was enabled by the favor of Pedrarias Davila to spend several years at one of the universities, probably that of Saragossa, and distinguished himself in literary studies, and especially in the athletic accomplishments of knighthood. In 1519 he accompanied his patron on his second expedition to America as governor of Darien, and was the most intrepid opponent of the oppressive administration of that officer. He supported Hernandez in Nicaragua in 1527, who perished by the hand of Davila, in consequence of not heeding his advice. Withdrawing from the service of Davila, he explored in 1528 the coast of Guatemala and Yucatan for 700 m., in search of the strait which was

supposed to connect the two oceans. It was by special request of Pizarro in 1532 that De Soto joined him in his enterprise for conquering Peru, with the promise of being appointed second in command. Being sent in 1533, with 50 horsemen and a few targeteers, to explore the highlands of Peru, he encountered and defeated 2,000 Indians, penetrated through a pass in the mountains, and discovered the great national road which led to the Peruvian capital, and was soon after selected by Pizarro to visit the inca Atahuallpa as ambassador. After the plot for the capture of the inca had proved successful, and the latter had paid an immense sum for ransom, De Soto in vain expostulated with Pizarro for treacherously refusing to release the Peruvian monarch. He was prominent in the engagements which completed the conquest of Peru, and was the hero of the battle which resulted in the capture of the metropolis, Cuzco. He soon after returned to Spain with a fortune of $500,000; met a flattering reception from the emperor Charles V., made a splendid display at court, and married the daughter of Davila, the object of an early attachment. In 1536 the belief was entertained that in the vast region then called Florida was a new El Dorado, richer than any that had been discovered. Of this faith De Soto became the martyr. He proposed to the emperor to undertake the conquest of Florida at his own expense; and the privilege being conceded to him, many Spanish and Portuguese cavaliers were ambitious to enroll themselves among his followers. With 600 men, the flower of the peninsula, exclusive of 24 ecclesiastics and 20 officers, he set sail from San Lucar early in April, 1538. After stopping at Santiago de Cuba, and then at Havana, where it was decided that the ladies attached to the expedition should remain till after the conquest of Florida, he crossed the gulf of Mexico, and anchored in the bay of Spiritu Santo (Tampa bay), May 25, 1539. His route was through a country already made hostile by the violence of the Spanish invader Narvaez, and he was constantly deluded by the Indians, whose policy it was to send their unwelcome visitors as far away as possible by telling them of gold regions at remote points. In July, 1539, he sent back all his ships to Havana. He discovered a Spaniard, Juan Ortiz, who had been in slavery from the time of Narvaez, and who now served as his interpreter. He passed the first winter in the country of the Appalachians, E. of the Flint river. Directed then to the N. E., he reached in April, 1540, the Ogeechee; thence proceeding to the S., he reached the Coosa, and on Oct. 18 the village of Mavilla or Mobile, on the Alabama. The engagement which ensued here was one of the most sanguinary battles ever fought between Europeans and the North American Indians; the loss of the Spaniards was 80 men and 42 horses; that of the Indians was reported at 2,500 men. Ships had meantime arrived at Ochus (Pensacola), but De Soto proudly refused to send back any message of his fortunes. He passed the second winter in the country of the Chickasaws, who in the spring burned his camp and their own village, when he attempted to force them to carry his baggage. Forty Spaniards perished in the flames, and in the night attack. Soon after beginning his march to the N. W., a pestilential fever carried off nearly a score of his men. He reached the Mississippi after journeying for 7 days through a wilderness of forests and marshes, was nearly a month in constructing 8 large barges to transport his army, and having crossed the river went N. to Pacaha, where he remained from June 19 till July 29. Thence he marched successively S. W. and N. W. till he reached the highlands of the White river, in the eastern portion of what is now the Indian territory. This was the western limit of his rambles. He then proceeded S. by the hot springs of Arkansas, which his companions at first supposed to be the fabled fountain of youth, and made his third winter station at Autiamque on the Washita river. In March and April, 1542, he continued S. along the Washita to the Mississippi, and while in vain attempting to descend the banks of the latter, through the bayous and marshes, he was attacked with a malignant fever, and died, after appointing Luis de Moscoso his successor. "His soldiers," says Bancroft, "pronounced his eulogy by grieving for their loss; the priests chanted over his body the first requiems that were ever heard on the waters of the Mississippi. To conceal his death, his body was wrapped in a mantle, and, in the stillness of midnight, was silently sunk in the middle of the stream. The wanderer had crossed a large part of the continent in search of gold, and found nothing so remarkable as his burial place." His followers, reduced more than one-half in number, venturing E., were driven backward to the river, where they passed the next winter. In the spring of 1543 they embarked in 7 boats, and after nearly 3 months the survivors reached the Mexican town of Panuco, now in the department of Vera Cruz, where they dispersed. The wife of De Soto expired at Havana on the third day after learning his fate.—A history of his life and travels, by L. A. Wilmer, was published at Philadelphia in 1858.

DESPARD, Edward Marcus, an Irish soldier, beheaded in London, March 21, 1803. He was a native of Queen's co., Ireland, a soldier in the West Indies, and superintendent of the English colony in Honduras. In consequence of complaints made against him he was recalled in 1790, but he could never procure an examination into his administration. This made him disaffected, and he was arrested for seditious conduct, but after his liberation he was only the more inflamed. He seduced some of the soldiers, and matured a plan to assassinate the king on his way to open parliament. The conspirators were arrested and tried by special commission at Southwark, Feb. 5, 1803. There being no doubt of their guilt, Despard and 9 of his associates suffered death.

DES PLAINES, or Aux Plaines (Indian

appellation, *She-shik-mah-o*), a river of Illinois, rising in the S. E. part of Wisconsin, flowing S. and S. W., and uniting with the Kankakee at Dresden, to form the Illinois. It is about 150 m. long, and derives its name from a species of maple called by the French *plaine*.

DESSAIX, Joseph Marie, a French general, born in Thonon, Savoy, Sept. 24, 1764, died Oct. 26, 1834. He was a physician at Paris, and in 1791 returned to his native country to diffuse democratic principles and organize a corps of volunteers. He served at the siege of Toulon, and in Italy under Bonaparte; was elected in 1798 to the council of 500, where he opposed the *coup d'état* of the 18th Brumaire; made a brigadier-general by Bonaparte in 1803, and, in the campaign of 1809 against Austria, a general of division, receiving from the emperor the surname of *L'intrépide*, and the title of count of the empire. Being wounded during the expedition to Russia, he was put in command of the city of Berlin, and in 1813 was intrusted with the defence of France on the line of the Alps. In 1814 he was kindly treated by the Bourbons, notwithstanding which he joined the standard of Napoleon after his landing at Cannes, and was imprisoned for 6 months in 1816. After the revolution of 1830, he was elected commander of the national guards at Lyons.

DESSALINES, Jean Jacques, emperor of Hayti under the name of Jean Jacques I., born about 1760, killed Oct. 17, 1806. He was a native of Guinea, and when a boy he was sold to a French planter whose name he adopted. On the revolt of 1791, Dessalines joined the insurgent army, and by energy and shrewdness, though entirely uneducated, soon obtained a prominent position. He became adjutant-general of the negro commander Jean François, who united his forces with those of the Spaniards against the French; and when Toussaint L'Ouverture suddenly left his Spanish allies and went over to the French side, Dessalines adhered to his fortunes. Having been raised to the rank of lieutenant-general, he led a successful campaign against the mulatto chief Rigaud. The promptness and energy evinced in this movement recommended him to Toussaint, who thenceforward always sent him where the utmost severity was considered necessary. His name spread terror wherever he went. Thousands of mulattoes were slaughtered, drowned, or shot by his orders. At the same time he led a most dissolute life, and enriched himself by extensive robberies perpetrated in the guise of legal confiscations. When Napoleon sent his brother-in-law, Leclerc, to reconquer Hayti, Dessalines conducted a bloody guerrilla war against the French, to which history scarcely furnishes a parallel. One of his most remarkable feats was the obstinate defence of the town of St. Marc against Gen. Boudet. When unable to hold the town any longer, he burned it down, himself setting fire to his own palace, butchered all the white inhabitants of the place, and likewise all whom he fell in with on his retreat. Peace having been made in 1802, by Christophe, Dessalines became a French general and governor of the southern portion of the island. Here he plunged once more into debauchery, but at the same time he intrigued against Toussaint, and, it is believed, secretly betrayed him. When Toussaint's nephew Belair rose against the tyranny of the French, Dessalines treacherously enticed him by promises of assistance, and had him murdered in cold blood with 300 of his followers. But his loyalty to the French was of short duration. Rochambeau, having succeeded Leclerc in the chief command of the French army of occupation, vied in bloodthirstiness with the savage negroes. Among others, he tortured to death the negro general Maurepas and his whole family. Dessalines resolved upon a terrible retribution. He erected 500 gibbets, and hung half a regiment of French whom he had captured by a bold countermarch. A brief war of extermination followed, and in Dec. 1803, aided by an English squadron, he definitively expelled the French from Hayti. In Jan. 1804, the army elected him governor-general of the new republic. For a few months he ruled in a spirit of moderation, and took some wise and just measures toward a healthy reorganization of the commonwealth. But soon his brutal nature prevailed over his judgment, and he returned to his favorite occupation of exterminating the whites. In April, 1804, he made an unsuccessful attempt to conquer the Spanish portion of the island, and after his return he became more frantic than ever. In imitation of Napoleon, he assumed the imperial crown (Oct. 8, 1804), and proclaimed a new constitution, which concentrated all real power in his own hands. A number of organic laws followed, most of them judicious, but inefficient, since his recklessness and eccentricities, bordering on absolute lunacy, frustrated their execution. His extravagance deranged the finances, his dissoluteness corrupted the morals of all classes. Beside his legitimate wife, he kept 20 concubines, who drew their salary from the public treasury. His thirst for blood became more and more insatiable. Suspicious of traitors and assassins, he put to death every one whom he supposed to have any independence of character. At last some of his generals entered into a conspiracy against him, and, entrapping him into an ambuscade, cut him to pieces. Of all fiends in human form who have obtained a place in history, Dessalines was undoubtedly one of the most remarkable. In a slender and hideous frame he united the wildest passions of the ferocious savage with extraordinary shrewdness, an undeniable keenness of judgment, and a clear statesmanlike knowledge of the men and things he had to deal with. However abominable his character may appear, it is nevertheless true that he understood the means of accomplishing the independence of Hayti better than even Toussaint himself. But he left Hayti a ruined and desolate, though an independent state. His widow, to whose influence are ascribed the few acts of forbearance

he exercised toward the whites, died in Gonaives, Aug. 8, 1858, at a very advanced age.

DESSAU, or Dessaw, the capital of the German duchy of Anhalt-Dessau, on the river Mulde, 2 m. from its junction with the Elbe, and on the Berlin and Leipsic railway, 67 m. S.W. from Berlin; pop. 12,000. The ducal residence is large, and has a fine park and a picture gallery. The theatre, the residence of the hereditary prince, the council house, the castle church, the government building, the gymnasium, St. Mary's church with some pictures by Lucas Cranach the younger, and the fine cemetery, are the most attractive features of the town. There are many scientific, artistic, religious, and industrial institutions and societies, a commercial school, a large ducal library, an orthopædic institution, and a bank with a capital of about $2,000,000. The manufactures embrace woollen, linen, and cotton fabrics, musical instruments, hats, leather, and tobacco. An important wool market is held here, and a flourishing trade in grain and other produce is carried on. Moses Mendelssohn, the philosopher, was born here in 1729. Dessau was noted as early as 1213, and in 1313 had a school independent of the church. In the German revolution of 1848 it was one of the most democratic cities of Germany. Its environs are adorned with beautiful gardens, which have been reclaimed from sandy wastes.

DESSOLLES, Jean Joseph Paul Augustin, marquis, a French general and statesman, born at Auch, Oct. 3, 1767, died Nov. 4, 1828. Having distinguished himself in Italy under the command of Bonaparte, he was appointed brigadier-general, May 31, 1797. A successful expedition in Valtelina was rewarded, April 13, 1799, with the rank of general of division. After the defeat of the French at Novi, where the commander-in-chief, Joubert, was killed, Dessolles joined the army on the Rhine, then under the command of Moreau, and participated in the two campaigns of 1800. He became attached to his new commander, and from this period a coolness seems to have existed between him and Bonaparte. He was, however, appointed a member of the council of state, and placed for a while in command of the French army in Hanover, but was soon superseded by Bernadotte. In 1808 he commanded a division in Spain. On the fall of Napoleon in 1814, the provisional government appointed him commander-in-chief of the Parisian national guards and the regular troops in the 1st military district. He was present at the meetings of the allied sovereigns at Talleyrand's, to decide upon the government to be given to France. He strenuously opposed the establishment of a regency under Marie Louise, and on the arrival of Count d'Artois he received the title of minister of state, and was appointed major-general of all the national guards of France. When the news of Napoleon's landing at Cannes reached Paris, Dessolles issued energetic orders to interrupt the progress of the usurper, and he retained his command until after the departure of the king on the morning of March 20, 1815. He then retired to his estate near Paris, where he lived unmolested during the Hundred Days. On the second restoration, he resumed the command of the national guard, but soon gave it up, being unwilling to support the reactionary policy then prevailing. In the chamber of peers he advocated the freedom of the press. On Dec. 28, 1818, he was appointed to the premiership and ministry of foreign affairs, receiving about the same time the title of marquis; but the king having determined that the electoral law of 1817 should be altered, Dessolles resigned his office, but continued to serve as a peer till his death.

DESTERRO, Nossa Senhora do Desterro, or Santa Catharina, a city of Brazil, capital of the province of Santa Catharina, on the W. coast of the island of that name; pop. with the adjoining district, 6,000. It has a small but excellent and well fortified harbor, and is the centre of an active commerce, the coffee exported hence bearing a high reputation. Artificial flowers made of fish scales, feathers, beetles' wings, &c., are also important articles of trade. The city has little or no architectural beauty, but is a favorite resort for invalids on account of its salubrious climate.

DESTOUCHES, Philippe Héricault, a French dramatist, born in Tours in 1680, died July 4, 1754. After leading a somewhat adventurous life, he was hospitably entertained at Lausanne by M. de Puysieux, the French envoy to Switzerland. His first comedy, *Le curieux impertinent*, was performed there with great applause, and was scarcely less successful when it appeared at Paris. Some other plays of his, among them *L'irrésolu*, attracted the attention of the regent duke of Orleans, who appointed him to several missions, the most important being that to London, where in 1717 he accompanied the abbé, afterward cardinal Dubois. After his return in 1723, on the sudden death of the regent, he retired to his country seat near Melun, where he wrote a number of comedies, the best of which are *Le philosophe marié* and *Le glorieux*, performed with great success in 1727 and 1732. His collected works were published in 1750, in 4 vols. 4to.

DESTUTT DE TRACY, Antoine Louis Claude, a French philosopher, born at Paray-le-Fresil, near Moulins, in the province of Bourbonnais, July 20, 1754, died near Paris, March 9, 1836. The descendant of a noble Scottish family, he entered the army, and was a colonel when the revolution broke out. As a deputy to the constituent assembly, he advocated liberal reforms, while adhering to the moderate party. In 1791 he retired to his country seat at Auteuil, and devoted his time to philosophical studies. During the reign of terror he was imprisoned, but liberated after the 9th Thermidor. The consular government appointed him a senator, and he was subsequently created a count of the empire. He published his *Éléments d'idéologie* in 1801, his *Grammaire* in 1803, and his *Logique* in 1805,

and was elected to the French academy in 1808. He took an active part in the fall of the empire; presented, April 2, 1814, in the senate, the motion of forfeiture against Napoleon; and entered the royalist chamber of peers, where he always voted with the majority. His *Traité de la volonté et de ses effets* appeared in 1815. He also wrote an *Essai sur le génie et les ouvrages de Montesquieu*, followed by a *Commentaire sur l'Esprit des lois*. A disciple of Locke, Condillac, and Hobbes, he belongs to the sensational or materialist school of philosophy. His theory of language is considered a masterpiece of analysis.

DETMOLD, the capital of the little sovereign principality of Lippe-Detmold, in Germany, on the river Werra and on the E. slope of the Teutoburg mountains; pop. 4,716. In the vicinity was fought the celebrated battle in which Arminius destroyed the army of Varus, A. D. 9, and also a battle between Charlemagne and the Saxons, in 783.

DETROIT, the chief city of Michigan, and capital of Wayne co., situated on the N. W. side of the Detroit river or strait, extending along the river nearly 4 m., of which over 2 m. presents a city-like appearance. The centre of the city is about 7 m. from Lake St. Clair and 18 m. from Lake Erie, 80 m. E. S. E. of Lansing, 302 m. W. of Buffalo, and 526 m. from Washington; lat. 42° 20′ N., long. 82° 58′ W. The river runs from Lake St. Clair to a point just below the city, in a direction about 30° S. of W., and from thence it runs nearly S. to Lake Erie, a distance of 15 m. The original bed of the river, before it was narrowed by docking out, was from 48 to 52 chains in width; but from the docks of the central portion of the city to the opposite docks of Windsor, in Canada, it is only about half a mile. The depth, in June, 1841, varied from 12 to 48 feet, averaging about 32 feet. The descent from Lake St. Clair to Lake Erie is about 6 feet, or 3 inches to the mile. The velocity of the current in the channel opposite the city is about 2¼ m. per hour. It rises and falls with the surfaces of the great lakes of which it is a connecting link, the average annual variation being only about 2 feet, and the extreme variation, from Feb. 1819, when it was the lowest, to July, 1838, when it was the highest ever known, was only about 6 feet. The waters of the river and lakes rise during a succession of wet seasons, and fall during a succession of dry ones. The Detroit river is so deep, and its current so strong and uniform, that it keeps itself clear, and its navigation is not affected (as the Ohio, Mississippi, and most other rivers are) by floods, droughts, sand bars, trees, sawyers, rocks, or dams of ice.—Where the principal part of the city is situated, the ground rises gradually from the river to the height of from 20 to 30 feet, at a distance of 15 to 30 rods from the river bank; it then falls off a little, and again rises gradually to the height of 40 to 50 feet above the river, which renders the drainage very good. The whole country for more than 20 m. back of the city is excessively level, rising gently and with great uniformity at the rate of about 5 feet in the mile. The Detroit river was visited by the French as early as 1610, but the first permanent settlement where the city of Detroit now stands was made in 1701 by a party under Antoine de la Motte Cadillac. It fell into the hands of the British in 1760, and was ceded with the country to the United States by the treaty of peace of 1783. Nearly the whole town was burned in 1805, after which its plot was changed under an act of congress in 1806. A portion of the city is regularly laid out, the streets running parallel with the river, and crossing each other at right angles thereto, though there are numerous irregularities. The streets and avenues vary in width from 50 to 200 feet, the most of them being either 60 or 66 feet, but some are 80, some 100, some 120, and a few avenues 200 feet in width. The inhabitants are supplied with water taken from the river opposite the upper part of the city, and raised by means of a hydraulic establishment and steam forcing pumps into a large reservoir about half a mile back from the river, sufficiently elevated to carry it in iron pipes to all parts of the city. Buildings are in course of erection (1859) for a court house, custom house, and post office. The Michigan insurance company bank is a fine building of shell limestone, which presents on its surface many beautiful petrifactions. The firemen's hall, odd fellows' hall, and some of the public school houses are also fine buildings. There are about 30 churches, of which several are large and splendid; many spacious and beautiful stores; some large and elegant dwelling houses, and several extensive hotels. There are various charitable institutions, and in 1857 there were 35 public and 22 private schools. There are 3 daily newspapers, each of which publishes a semi-weekly and weekly edition; there are also 5 other weekly newspapers, a monthly medical journal, a monthly journal devoted to education, and 2 semi-monthly "bank-note detectors." The following table shows the increase of the population:

Year.	Pop.	Year.	Pop.
1810	770	1850	21,019
1820	1,442	1854	40,373
1830	2,222	1855, estimated at	51,000
1834	4,968	1856	59,000
1840	9,102	1858	70,000
1845	13,065		

In 1858 there were about 12,000 to 15,000 Irish, an equal number of Germans, and about 4,000 French.—The U. S. government made 5 great leading roads (post roads) in Michigan while it was a territory, all diverging from Detroit. The Michigan central railroad was finished to Ypsilanti, 30 m. from Detroit, in 1837; to Ann Arbor, 38 m., in 1839; to Kalamazoo, 145 m., in 1845; and to Chicago, 282 m., in 1851. The railroad from Detroit to Toledo (60 m.) was completed in 1857, connecting at Monroe with the Michigan southern road. The Detroit and Milwaukee road, from Detroit to Lake Michigan, opposite Milwaukee, was opened for travel in 1858; and a road from Detroit to the foot of

Lake Huron, opposite Port Sarnia, the termination of the Grand Trunk railway in Canada, will be finished in the course of 1859.—Detroit is the great concentrating point of the produce, commerce, banking, and heavy business of the whole state. There are numerous large warehouses on the river, beside the great freight depot of the Central railroad, which is 800 feet long and 100 feet wide. The retail trade of the city is very large, and the wholesale business has become extensive also. Nearly all the merchants in the upper lake region, as well as in the interior of the state, make many of their purchases in Detroit, and a large proportion of them buy all their goods there. The largest branch of industry is the sawing of lumber. There are on the river within the city limits 9 large steam saw mills, which cut from 3,000,000 to 8,000,000 feet each per annum, making in the whole about 40,000,000 feet annually of pine lumber, the logs being floated down to the mills from Lake Huron and the creeks and streams which fall into the St. Clair river. Ship and boat building has also been a very large and important branch of business. The Michigan central railroad company have an extensive workshop for the manufacture of cars, and for repairing their locomotive engines. The Detroit locomotive works are connected with a large foundery, machine shop, and boiler factory, for the manufacture of locomotive and other engines, and the casting of mill irons and machinery of various kinds. There are many other establishments, large and small, for all kinds of machine work, and brass and iron casting, beside shops for working in wood, making sash, blinds, doors, casings, &c.; 2 steam pail factories, one steam flouring mill, 2 large tanneries, and several breweries. Two miles below the city works have been erected and in operation several years for smelting native copper and copper ore from the shores of Lake Superior; 10 m. below, a blast furnace and rolling mill have been in operation several years. The furnace is employed in smelting ironstone from the upper peninsula. From 10 to 15 m. from the south shore of Lake Superior there are several hills of ironstone, very rich in the finest quality of iron, which will furnish an inexhaustible supply. The following table shows the industrial progress of the city from 1855 to 1857:

Establishments.	1855.	1856.	1857.
Stores	335	383	420
Groceries	260	247	280
Taverns	49	52	56
Offices	175	236	255
Mechanic shops	343	399	421
Stationary steam engines	46	50	69
Forwarding houses	24	26	29
Iron machine shops	10	11	10
Iron founderies	7	8	11
Breweries	17	20	23
Bakeries	21	27	28
Fire engine houses	9	9	13
Flour mills	3	4	5
Saw mills	6	6	9

The estimated value of the leading articles of export in 1857 was $10,996,399, and of the total foreign imports $1,139,791 64. The imports by railway of flour and grain in 1857 and 1858 were as follows:

Articles.	1857.	1858.
Flour, bbls	482,192	592,287
Wheat, bushels	650,874	839,704
Corn, "	447,219	231,040
Oats, "	196,564	150,486

The number of vessels built in the Detroit collection district during the fiscal years 1856–'7, ending June 30, with their aggregate tonnage and the total tonnage of the district, are as follows:

Vessels.	1856.	1857.
Steamers	9	10
Ships and barks	1	1
Brigs	..	1
Schooners	22	7
Sloops and boats	1	10
Total number built	33	29
Tonnage of do	7,626	6,764
Tonnage of district	58,688	57,707

The assessed valuation for purposes of taxation was, in the latter part of 1858, $16,360,000, with a city debt of about $300,000.

DETROIT RIVER. See DETROIT.

DEUCALION, king of Phthia, in Thessaly, and son of Prometheus and Clymene. According to ancient tradition, being forewarned by his father of an approaching deluge, he built a ship in which he and his wife Pyrrha were saved from an inundation which destroyed all the rest of mankind. When the waters subsided, their vessel rested on Mount Parnassus, and their first care was to consult the oracle of Themis as to how the world should be repeopled. Being advised to throw behind their backs the bones of their great mother, and interpreting mother to mean the earth, they cast stones behind them, from which sprang up men and women.

DEUTERONOMY (the second law; Gr. δευτερος, second, νομος, law), the 5th book of the Pentateuch, containing the history of what passed in the wilderness during about 5 weeks (from the beginning of the 11th month to the 7th day of the 12th month), in the 40th year after the departure of the Israelites from Egypt. In it Moses recites to the people the events which had taken place in their history, and explains again the law which had been received at Sinai.

DEUX PONTS (Ger. *Zweibrücken*, two bridges), a canton and town in the circle of the Palatinate, Bavaria; pop. of the canton, about 150,000; of the town, 7,920. The canton was formerly an independent duchy, and in 1795 came by inheritance into the possession of the king of Bavaria. During the wars of the French revolution it passed into the hands of the French, to whom its possession was confirmed by the treaty of Luneville in 1801. In 1814 it was finally restored to Bavaria. Much of the canton is mountainous, but in the valleys and on the lower hills agriculture is carried on to a considerable extent. It has extensive forests, and iron, copper, and freestone are found. Much attention is also paid to the raising of

horses, cattle, and sheep.—The town of Deux Ponts was the capital of the ancient duchy, and once possessed a handsome ducal palace, which was partially destroyed by the French, and has since been converted into a church. The name of the town, which in Latin is *Bipontium*, was given to it on account of the two bridges across the Erlbach, near the old castle of the dukes. The Bipont editions of the Greek and Latin classics were commenced here in the latter part of the 18th century.

DEV (Sanscrit, *div*, to play, desire, shine, be mad or proud, tease, &c.; Slavic, *div-iti*, to wonder; *dzrir*, wild), the Parsee name of the *peetiare Ahriman*, or evil-breeding principle, and of his progeny of night, death, darkness, drought, dulness, dearth, dirt, negation, and starvation. The devs were the producers of these and of all other dire and dreadful calamities, as well as the seducers of men to all moral evils; the prototypes of the devils of Christian history. For the διαβολος (scatterer, confounder) itself seems to be of recent formation in this sense, having been unknown to the ancient Greeks. As Ahriman, though akin to Ormuzd, both being the offspring of Zervane Akerene (Slav. *trvanie*, duration, *a* privative, and Slav. *kraj*, margin), or endless time, was his antagonist, so were the 6 arch-devs opposed to as many Amshaspands representing the principles of light, life, love, law, right existence, and happiness; both being also the prototypes of the 7 choirs of devils and of angels. Beside the regular army of evil spirits, rushing down from the desert of Gobi upon the south-western people of Ormuzd, compelling them to leave their native land, Eeriene Veedjo (*Iran*, pure), under the guidance of Jemshid, and to change their settlements 13 times, there were especial devs of falsehood, envy, putridity, and all other evil things, distinguished by specific names, such as Eshem, the man-killer; Akuman, the ugliest of all; Epeosho, the destroyer of waters in the shape of a dragon-star (probably a comet), &c. The Darudjs, a particular sort of devs, opposed to the good Izeds, or secondary good genii, are also conspicuous. The ever renewed contest of the two principles will end with the destruction of the earth by the comet Gurzsher. The cosmogony and theology of the Parsees is contained in the Zend Avesta.

DEVA (Lat. *deus*, *divus*), among the Aryans in general, an epithet of divine persons and things; hence often opposed to the *dev* of the Parsees. It is commonly applied to the goddess Durgā, the wife of Siva, of terrific form and irascible temper. Devakātmajā is the mother of Krishna, who is also named Devāki. Devatarū is the holy fig-tree, belonging to Sverga or paradise. Devatā denotes a deity; Devadatta, the younger brother of Buddha, who is called Devadattārraja (Deodatus senior). Devadeva is a name of Brahma; Devapati is Indra, the god of the sky; Devayajna is the Homa or burnt sacrifice; Devarishi, a celestial saint. There are a great many classes or choirs of inferior devatas, who are ministers to the higher gods, such as the 12 Adityas or forces of the sun; the Maruts or winds, the celestial musicians; in short, endless motley hosts with variable attributes. (See Brahma.)

DEVANAGARI. See Sanscrit.

DEVAPRAYAGA, a town of Gurhwal, Hindostan, situated at the place where the rivers Bhagirathi and Alakananda unite and form the Ganges. This portion is considered by the Hindoos as the most sacred part of that holy river, and is believed by them to have the property of washing away sins. The town is not large, and is inhabited principally by Brahmins, who are supported chiefly by the contributions of pilgrims. It is built on an eminence about 100 feet above the river, and contains a celebrated Hindoo temple, built of large stones joined together without the use of mortar.

DEVENTER, or Dewenter, a fortified city of Holland, province of Overyssel, on the Yssel, 8 m. N. from Zutphen; pop. in 1850, 14,378. It has narrow streets, spacious market places, handsome public promenades, a large town house, a court house, a prison, a weigh-house, 5 churches, a synagogue, various literary and educational institutions, 6 hospitals, and an orphan asylum. It has an excellent harbor, a prosperous trade, and extensive manufactories of Turkey carpets, stockings, iron ware, &c. It exports annually about 600,000 lbs. of butter.

DE VERE, Maximilian Schele, professor of modern languages and belles-lettres in the university of Virginia, born near Wexio, in Sweden, Nov. 1, 1820. He first entered the military and afterward the diplomatic service of Prussia. Emigrating finally to the United States, he was appointed in 1844 professor in the university of Virginia, a position which he continues to occupy. Prof. De Vere has been an industrious and extensive writer, as well as a laborious student and teacher. His contributions upon a great variety of subjects, of a historical, literary, and scientific character, have appeared in the British quarterly reviews, the "Southern Literary Messenger," in "Putnam's" and "Harper's" magazines, and elsewhere. He has published 2 volumes: the first in 1853, "Outlines of Comparative Philology;" the second in 1856, "Stray Leaves from the Book of Nature." The former is a very full and comprehensive treatise, now in use as a text book at the university of Virginia; the latter a graceful and pleasing series of papers, dealing with a number of curious and interesting subjects, chiefly in the department of the minute naturalist. The miscellaneous articles contributed by Professor De Vere to the periodicals mentioned above have been valuable and interesting; among them we refer especially to a series of papers in the "Southern Literary Messenger," entitled "Glimpses of Europe in 1848," which are remarkable for political insight and vivid coloring. He has made himself master of English, and writes it with much perspicuity, force, and elegance.

DEVEREUX, Robert, 1st earl of Essex, born about 1540, died in Dublin, Sept. 22, 1576. He succeeded his grandfather early in the title of Viscount Hereford, and recommended himself to Queen Elizabeth by his bravery and good conduct in suppressing the rebellion of the earls of Northumberland and Westmoreland, in 1569. For his service in driving them into Scotland he received the garter and the earldom of Essex. Afterward, in 1573, he was persuaded to undertake an expedition against Ireland, in company with other noblemen and gentlemen. In consideration of his contract to furnish half the expense of the enterprise, he was to have one-half of the colony as soon as it was established. The expedition was directed against the Irish province of Ulster, but in its prosecution Essex was subjected to many trials and disappointments, to the desertion of his friends, and inability to carry out his plans. He was obliged to make peace with O'Neal, when, by continuing the war, he had the fairest prospects of driving him out of the country. Harassed with his difficulties, he retired to England, but was again induced to return, with the title of earl marshal of Ireland and the promise of support and assistance. As these promises were but poorly kept, he was overcome with grief, and the agitation of his mind threw him into a fatal dysentery. There was suspicion of poison, which was not diminished by the marriage, soon after, of his countess to the earl of Leicester.

DEVEREUX, Robert, son of the preceding, 2d earl of Essex, born at Netherwood, in Herefordshire, Nov. 10, 1567, executed in the court of the tower, Feb. 25, 1601. He succeeded to his title in his 10th year, and in 1578 was sent by his guardian Lord Burleigh to Trinity college, Cambridge, where after 4 years he took the degree of master of arts. He retired to his seat at Lampsie, in South Wales, but appeared at court in his 17th year, and his youth, address, and spirit soon captivated Elizabeth. In 1585 he accompanied the earl of Leicester to Holland, and displayed his personal courage in the battle of Zutphen, in which Sir Philip Sidney fell mortally wounded. In 1587 he was appointed to the honorable post of master of the horse, and in the following year the queen ostentatiously showed her favor for him while reviewing the army at Tilbury, created him captain-general of the cavalry, and conferred on him the honor of the garter. He succeeded Leicester as prime favorite, and his attendance was constantly required at court. In 1589, when an expedition against Portugal was undertaken by Drake and Norris, Essex suddenly disappeared from court, followed the armament, and joined it on the coast of Portugal, where he was a leader in taking the castle of Peniche and in advancing upon Lisbon. Though he had departed without the permission of the queen, he was quickly reconciled with her after his return, and at once assumed a superiority over Sir Walter Raleigh and Sir Charles Blount, the rival competitors for royal favor. He was challenged by Blount and wounded in the knee, and the queen is said to have expressed her gratification that some one had taken him in hand, as otherwise there would be no ruling him. In 1590 he married the daughter of Sir Francis Walsingham, the widow of Sir Philip Sidney, and in the following year had command of a fruitless expedition in Brittany against the Spaniards, who were attempting its conquest. When, in 1596, alarm was excited by the hostile preparations in the Spanish harbors, he was joined with Lord Admiral Howard in command of the expedition against Cadiz, and entered the city by land soon after the engagement in the harbor, in which 13 Spanish ships of war were taken or destroyed. The intrigues of the Cecils, who had regarded Essex with jealousy from his first introduction at court, caused him to be coolly received on his return; but he quickly recovered favor, the queen preferring him as an accomplished courtier and Sir Robert Cecil as a man of business. Two subsequent expeditions which he conducted against Spanish shipping, in one of which Lord Thomas Howard and Sir Walter Raleigh were his seconds, met with little success. The queen received him with frowns and reproaches, and he retired to Wanstead; nor would he be pacified by her acknowledgment that the charges against him were unfounded, but after a long negotiation he accepted the office of hereditary earl marshal as indemnity for the promotion that had been given to his rivals. In 1598 he quarrelled with the queen about the appointment of deputy in Ireland, and when she boxed him on the ear, and bade him "go and be hanged," for turning his back to her in presence of her ministers, he swore that he would not endure such an affront even from Henry VIII. himself, and withdrew from court. Only a formal reconciliation was ever effected. In 1599 the province of Ulster was in rebellion, and Essex, invested with unusual powers, accepted the lord-lieutenantcy of Ireland. His campaign resulted only in a temporary armistice, and completed his ruin. He returned in haste, retired from his first audience with a cheerful countenance, but was immediately ordered to consider himself a prisoner in his own house, and was for a time delivered to the lord keeper to be kept in "free custody." After months of hesitation, both on his own part and that of Elizabeth, he at length conceived the plan of forcibly banishing his enemies from her majesty's council. At the head of a force of 80 knights or gentlemen, and about 200 other persons attached to him by friendship or fear, he made his way into the city, but was disappointed in expecting the people to rise in his favor; he completely failed in his design, and took refuge in Essex house, where he was besieged and forced to surrender. He was committed to the tower, tried for treason, condemned, and executed, the queen reluctantly and irresolutely signing the warrant. He was an accomplished scholar, a patron of literature, and the most frank and impetuous of the politicians of his time. He erected a monument to Spen-

ser, gave an estate to Bacon, and was the friend of Wotton and other men of learning.

DEVEREUX, Robert, son of the preceding, 3d earl of Essex, born in London in 1592, died in the same city, Sept. 14, 1646. He was educated at Eton and at Merton college, Oxford. He succeeded to his title in 1603, and in his 15th year was married to Lady Frances Howard, who was a year younger than himself. He proceeded to the university and thence to the continent, while his wife remained at court, and numbered Prince Henry and Rochester (afterward earl of Somerset) among her admirers. A divorce ensued between her and the earl of Essex, on the plea of his natural incapacity, and she was soon after married to Rochester. Essex led a solitary life in his country house, till in 1620 he raised a troop and served under the elector palatine in the wars of the Netherlands. He was engaged in several campaigns abroad, and as vice-admiral commanded a fruitless expedition sent by England against Spain. His second marriage resulted unhappily and in a divorce. At the outbreak of the civil war he was appointed lord general by the parliament, laid siege to Portsmouth, and was proclaimed a traitor by Charles. He fought against the king at Edgehill (1642), captured Reading (1643), advanced into Cornwall, and, after refusing to negotiate with the royalists, met with a succession of disasters which forced his army to capitulate, he himself escaping in a boat to Plymouth. He repaired to London, where a parliamentary deputation waited on him in honor of his faithful services. He again raised a corps, but ill health soon obliged him to quit his command. As early as 1644 he suspected Cromwell of a design to obtain the supreme command of the army, abolish the house of lords, and erect a new government according to his own principles. He therefore urged his impeachment before the house of lords, and Cromwell took revenge by proposing the "self-denying ordinance," by which members of both houses were excluded from all offices, whether civil or military. This measure having passed, Essex ceased to be a parliamentary general, but for his services £10,000 per annum was voted to him out of the sequestered estates of the loyalists. He died in the next year, and was interred in Westminster abbey, the houses of parliament expressing their respect for his memory by attending his funeral.

DEVIL (Gr. διαβολος, scatterer or accuser), in Jewish and Christian theology, the sovereign spirit of evil. The doctrine of the fathers of the church, founded upon certain passages of the Scriptures, makes him the leader of a rebellion in the angelic world, the enemy of God, the author and constant promoter of sin, now suffering chastisement for his crimes, and destined to eternal punishment. Though called the prince of this world, and though all heathendom was the effect of his agency, yet his power was broken by the work of Christ, so that Christians can rise superior to the might of his influence. As sovereign of the demons, he figured prominently in the practice of magic and in many of the poetical legends of the middle ages. In the mysteries he was often represented on the stage, with black complexion, flaming eyes, sulphuric odor, horns, tail, hooked nails, and cloven hoof. Milton in the character of Satan, and Klopstock in that of Abbadonna, have personified the devil as a fallen angel, still bearing traces of his former dignity amid the disfigurements caused by sin. The Mephistopheles of Goethe is a more malignant character, and chuckles in anticipating the ultimate ruin which he is preparing by his arts.—The Yezidis, a singular race found in Koordistan and Armenia, are perhaps the only acknowledged worshippers of the devil. They seem to have once professed Christianity, then Mohammedanism, and now risk their destiny on devilism. Admitting that the mighty angel Satan, the chief of an angelic host, at present has a quarrel with God, they yet believe that a reconciliation will hereafter take place, and that he will be restored to his high estate in the celestial hierarchy. This is the foundation of their hope, and they esteem their chance for heaven a better one than if they trusted to their own merits or to the merits of the leader of any other religion whatsoever. (See Demons.)—Among the most complete theological treatises on the subject are those of Mayer, *Historia Diaboli* (2d ed., Tübingen, 1780); Semler, *Versuch einer biblischen Dämonologie* (Halle, 1785); and Schulz, *Untersuchung über die Bedeutung des Worts Teufel und Satan in der Bibel*.—The devil, as the ideal of evil, vice, craft, cunning, and knavery, has played a prominent part in literature. The following are examples: Hocker, *Wider den Bann-Teufel* (Magdeburg, 1564); Musculus, *Wider den Ehe-Teufel* (Frankfort, 1566); Fabricius, *Der heilige, kluge, und gelehrte Teufel* (Eislingen, 1567); Luberti, *Fast-Nachts-Teufel* (Lübeck, 1573); Brandmüller, *Der Geiz-Teufel* (Basel, 1579); Musäus, *Melancholischer Teufel* (Tham, 1572), and *Speculativischer Teufel* (Magdeburg, 1579); the *Theatrum Diabolorum* (Frankfort, 1565, containing 20 old German writings similar to the preceding); Velez de Guevara, *El diabolo cojuelo* (Barcelona, 1646); Damerval, *Le livre de la diablerie* (Paris, 1508); *Le diable bossu*, *Le diable femme*, *Le diable pendu et dépendu*, *Le diable d'argent*, *Le diable babillard* (all early in the 18th century); *Le diable confondu* (the Hague, 1740); *Le diable hermite* (Amsterdam, 1741); Le Sage, *Le diable boiteux* (Paris, 1755); Frédéric Soulié, *Mémoires du diable* (Paris, 1844); the "Parlyament of Deuylles," printed by Wynkin de Worde (1509); the "Wyll of the Deuyll and Last Testament;" the "Devill's White Boyes" (1644); "Devil turned Roundhead" (London, 1642); the "Devill of Mascon" (Oxford, 1658); and Defoe, the "Political History of the Devil, as well Ancient as Modern" (London, 1726).

DEVIL-FISH, a cartilaginous fish of the ray family, and the genus *cephaloptera* (Duméril).

In this genus the head is truncated in front, and provided on each side with a pointed, wing-like process, separate from the pectoral fins, and capable of independent motion; these processes, however, seem sometimes to be prolongations of the pectorals, and give the name to the genus, which signifies wings upon the head. The pectorals are of great breadth, triangular, resembling wings, and making the transverse diameter of the fish greater than the longitudinal, with the tail included; the jaws are at the end of the head; the lower are the most advanced; the eyes are prominent and lateral; the tail is armed with one or two serrated spines, and is long and slender; in front of the spine is a small dorsal fin with 36 rays; the teeth are small, numerous, flat, and arranged in many rows; the small nostrils are placed near the angles of the mouth, and openings (probably the auditory) are situated on the dorsal aspect of the appendages to the head, behind the eyes; the branchial openings are 5 on each side, large, linear, near each other, the 5th being the smallest; the ventral fins are small, rounded, near the base of the tail; the skin is rough to the touch, like that of some sharks; the skeleton is cartilaginous. The old genus *cephaloptera* has been divided by Müller and Henle, and the genus *ceratoptera* added. In the first the mouth is on the ventral aspect, and the pectorals are prolonged forward to a point beyond the head, resembling horns; 4 species are described. In the second the mouth is at the end of the snout, the upper jaw is crescentic, and the under convex; there are no teeth in the upper jaw, and they are small and scale-like on the under; the pectorals are separated from the precephalic fins by a rayless space; this includes 3 species, and among them, probably, the one mentioned below as caught at Kingston, Jamaica. The devil-fish mentioned by Catesby, in his "Natural History of Carolina," is probably the same as the gigantic ray described by Mitchill in vol i. of the "Annals of the Lyceum of Natural History of New York," under the name of the "vampire of the ocean" (*C. vampyrus*, Mitch.). This specimen was taken in the Atlantic, near the entrance of Delaware bay, in 1823, and was so heavy as to require 3 pair of oxen, a horse, and several men to drag it on shore; it was estimated to weigh about 5 tons, and measured 17¼ feet long and 18 feet wide; the skin on the back was blackish brown, and on the belly black and white, and very slimy; the mouth was 2¾ feet wide, the greatest breadth of the skull 5 feet, and the distance between the eyes 4⅙ feet; the cranial appendages were 2½ feet long and a foot wide, tapering, supported internally by 27 parallel cartilaginous articulated rays, allowing free motion in almost all directions, and probably used as prehensile organs; the immense pectorals were attached to the scapular arch, and contained 77 articulated parallel cartilaginous rays, and were used like wings to fly through the water. The specific name of this ray was given by Mitchill from its size, representing in its family what the vampire does in the bat family. This specimen was again described by Lesueur in the "Journal of the Academy of Natural Sciences" (vol. iv., 1824), as *C. giorna* (Lacép.). Cuvier and Dekay consider the latter a distinct species, rarely exceeding the weight of 50 lbs. The devil-fish is occasionally seen by the fishermen on the coast of the southern states in summer and autumn, and many wonderful stories are told of its strength and ferocity, its extraordinary shape and size having transformed a powerful but inoffensive animal into a terrible monster in the eyes of those who cannot see the admirable adaptation of means to ends even in the most hideous creatures. Other species of the genus are met with in the tropical parts of the Atlantic and Pacific, both in mid ocean and on sandy coasts, which they approach to bring forth their young; and doubtless many of the marvellous stories of the sea serpent and other marine monsters have arisen from the sight of these animals sporting on the surface of the water, or dimly seen beneath the vessel's keel. They are not uncommon in the West Indies, and Dr. Bancroft, in vol. iv. of the "Zoological Journal," describes one which was captured in 1828 in the harbor of Kingston, Jamaica, after a resistance of several hours, which had strength sufficient to drag 3 or 4 boats fastened together at the rate of 4 miles an hour. In this specimen, which was smaller than the one described by Mitchill, the mouth was 27 inches wide, opening into a cavity 4½ feet wide and 3 feet deep, and so vaulted that it could easily contain the body of a man. He named it *C. manta*, which is doubtless a synonyme of *C. vampyrus* (Mitch.). In Anson's "Voyage round the World" there is an account of an immense fish which, "broad and long, like a quilt, wraps its fins round a man that happens to come within its reach, and immediately squeezes him to death." Another writer says that it is so inimical to the pearl diver that it darts at him "immediately that he submerges, and envelops and devours him." The fish thus characterized is, no doubt, the ray called devil-fish, but it is anatomically impossible that it can so seize its prey; the accounts above mentioned are mere traditions, as it does not appear that any one has ever been a witness of such an event. The pectoral fins of the devil-fish are too thick at their base and anterior margin, and their cartilages are too rigid, to allow of their being so bent downward as to enfold a man or any other prey in the manner alluded to; they are composed of a great number of joints, more than 600, and must be capable of a considerable variety of motions calculated to impel the animal through the water with great strength and speed; any one who has caught a skate, and experienced the resistance of a fish 2 or 3 feet in diameter, can readily believe that an animal 18 feet in extent of fins might, if entangled in the cable of a small vessel, draw it for miles with considerable velocity, as was observed by Catesby, and has since happened in the harbor

of Charleston, S. C.; it is equally conceivable that by means of the immense pectorals they could raise a great commotion on the surface of the water, and even leap entirely out, yet the pectorals must be considered as organs of locomotion, and not of prehension. The appendages to the head can hardly be used in locomotion; Lieut. St. John, who has watched attentively the movements of this fish, says that these flaps are used in driving a large quantity of water toward the mouth when the animal is at rest, feeding; they can be bent in front of, and even into the mouth, and are probably prehensile organs for various purposes; when swimming, the flexible ends are coiled up. The nature of the teeth, and the narrowness of the gullet, also render it improbable that this fish feeds upon any thing but small fry, which it sweeps toward the mouth by its cranial flaps. The truth appears to be that the devil-fish, though powerful and hideous, is a timid and harmless creature, avoiding rather than attacking man; but when attacked and defending itself, the serrated spine of the tail would prove a dangerous weapon, inflicting a deep, lacerated, and possibly fatal wound to man or fish within its range. They are gregarious, and are pursued by fishermen for the oil which the liver contains.—Another large and hideous fish, sometimes called sea devil and devil-fish, is the *lophius piscatorius* (Linn.), which will be described under the title of Goose Fish.

DEVIL'S ADVOCATE. See Advocatus Diaboli.

DEVIL'S BRIDGE, a remarkable stone bridge over the Reuss, in Switzerland. It is on the road from Germany to Italy, over the pass of St. Gothard, and crosses the river from mountain to mountain, a distance of about 75 feet. It is one of the most ancient structures of the kind in Switzerland, though there are others which surpass it in height, length, and width. The surrounding country abounds in romantic and beautiful scenery.

DEVIL'S WALL, a name given during the middle ages to the remains of some Roman fortifications designed to protect the Roman settlements on the Rhine and the Danube against the inroads of the free German tribes. These defences originally consisted of a row of palisades, in front of which extended a deep ditch. The emperor Probus strengthened them by the erection of a wall 368 m. long, passing over rivers and mountains, and through valleys, and protected by towers placed at intervals. The only portions of this wall now distinguishable are between Abensberg, in Bavaria, and Cologne, on the Rhine. In some places the ruins are overgrown with oaks, in others they form elevated roads or pathways through dense forests, while not unfrequently modern edifices have been built above them.

DEVISE. By this term is designated the disposition of lands to take effect after the death of the devisor. It is of Norman origin, and signified at first any division of lands, *marque de division ou partage de terres*, from the Latin *divido*. The instrument by which lands are devised is called a will; the disposition of personal estate to take effect after the death of the person making it is in legal language a testament; but the common appellation, where both real and personal estate are included, is last will and testament. The Roman *testamentum* applied equally to the disposition of real or personal estate, and the same rules were observed in either case. But the mode of executing a will has been always more formal in England than was required for the validity of a testament.—For a further explanation of the principles applicable to devise, see Will.

DEVIZES, a parliamentary borough and market town of Wiltshire, England, built on a fine eminence on the Kennet canal, 82 m. S. W. of London; pop. in 1851, 6,554. It has 3 silk factories; the woollen manufacture, once carried on, is now extinct. The town is supposd to owe its origin to a strong castle built here in the reign of Henry I. by Roger, bishop of Salisbury, and dismantled toward the close of the reign of Edward III. The grain market held here every Thursday has been famous ever since the time of Henry VIII.

DEVONIAN, the name of one of the great geological formations, including the old red sandstone, and the groups below it to those of the upper silurian. It is named from South Devon in England, where its strata were first distinguished in 1837 from those of the silurian and carboniferous by Prof. Sedgwick and Sir R. Murchison. The formation is recognized by its fossils and relative position in various parts of Europe; but it is nowhere found so largely developed as in the United States. In the New York system of the rocks it includes the following groups, though it is thought by Prof. Hall that the fossils of the 3 last named nearly resemble those of the Ludlow group of Murchison, and that these should consequently be referred to the upper silurian:

Names.	Approximate thickness in N. Y.
Catskill group, or old red sandstone	2,000 feet
Chemung	1,500 "
Portage / Genesee	1,000 "
Tully	15 "
Hamilton	1,000 "
Marcellus	50 "
Corniferous / Onondaga	50 "
Schoharie / Caudi-galligrit	10 "
Oriskany sandstone	5 to 30 "

Of these groups, some of the thickest thin away in other states, while others, as the calcareous strata of the corniferous and Onondaga groups, which together seldom exceed 50 feet in thickness in New York, spread out over the western states between the great lakes and the Ohio and Tennessee rivers in almost continuous strata of coralline rocks. Sir Charles Lyell notices a fine display of these calcareous rocks at the falls of the Ohio at Louisville. In the horizontal water-worn strata, "the softer parts having de-

composed and wasted away, the harder calcareous corals stand out in relief, their erect stems sending out branches precisely as when they were living." Fine specimens of various species of coralline are obtained at this locality, and new are continually brought out by the action of the river upon the rocks, and may be collected at low stages of the water. But only 6 species found in this country in the whole Devonian series are identified with the 46 British Devonian corals described in 1853 by Milne-Edwards and Jules Haime. The formation abounds with the greatest variety of fossil molluscous animals and crinoïdea, the genera of which, and some of the species, are identified with the Devonian fossils of Europe.

DEVONPORT, a parliamentary and municipal borough and naval arsenal in Devonshire, England, built on the Tamar, where that river makes a bold sweep toward the E., and widens into the fine estuary called the Hamoaze, just before its entrance into Plymouth sound, 218 m. S. W. of London, and 1½ m. W. of Plymouth; pop. in 1851, 50,159. Its harbor, one of several remarkable natural havens opening into the sound, is 4 m. long, ½ m. wide, from 15 to 20 fathoms deep, perfectly safe, and capable of sheltering the whole British navy at once; but it is difficult of entrance. The town is bounded S. and W. by the river, and E. by a creek which separates it from Stonehouse, contiguous to Plymouth. With these two places it is so closely connected, that the 3 may almost be said to form a single city, and it was not until 1824 that Devonport acquired separate municipal privileges, and changed its old name of Plymouth Dock for that which it now bears. A fluted column of the Doric order, approached by a flight of 140 steps, was erected in commemoration of the event. There are 6 churches, 2 chapels of ease, 17 places of worship for dissenters, 17 principal schools, including a naval and military free school, and an institution in which 100 girls are educated and clothed, a public library, orphan asylums, and a theatre. Water is brought from Dartmoor, in a winding conduit nearly 30 m. long. With the exception of some breweries and soap-boiling houses, Devonport contains no factories of importance. The density of the population is greater than that of any other place in England, there being no fewer than 26,000 people living on ½ of a sq. m., with an average of 10 individuals to each house, whereas the proportion in Liverpool is but 7, and in Manchester but 6. Devonport is fortified on the N., S., and E. by a wall, a breastwork, and a deep ditch, while the entrance from the sea is commanded by several heavy batteries. These works were begun by George II. The chief feature of the town is the dock yard, commenced by William III., who built the basin and 2 docks. It has a river front of 3,500 feet, and a maximum breadth of 1,600 feet, the area enclosed being about 96 acres. There are 2 dry docks, one double and one single dock for ships of the line, one graving dock, 5 building slips, and vast docks or basins at Point Keyham for fitting and repairing war steamers, commenced in 1844, and embracing an area of 72 acres. The immense roofs over the docks, consisting of single arches, without buttresses or pillars, are wonders of architectural skill. A canal 70 feet wide runs nearly through the yard, communicating with the boat pond. On the S. side are an outer mast pond and mast house, timber berths, saw pits, a smithery with 48 forges, an inner mast house and mast locks, a building in which planks are steamed and curved, a hemp magazine, and a rope factory, consisting of 2 stone and iron buildings, each 1,200 feet long and 3 stories high. The number of men employed in the whole establishment sometimes amounts to 3,000.

DEVONSHIRE, a maritime co. of England, second in size only to that of York, its greatest extent from N. to S. being 71 m., from E. to W. 72 m.; area, 2,585 sq. m.; pop. in 1841, 532,959; in 1851, 567,098. It is bounded on the N. and N. W. by the Bristol channel; on the W. by the river Tamar and Marsland-water, which separate it from Cornwall; on the S. and S. E. by the British channel; and on the E. and N. E. by the counties of Dorset and Somerset. The rivers of Devon are the Taw, Torridge, Tamar, Dart, Teign, Exe, Tavy, Plym, Yealm, Erme, Avon, Otter, Sid, Axe, and Lyn. Trout are found in great plenty in most of these; the Tamar and Tavy furnish valuable salmon fisheries; the Exe salmon are thought the best in England; and at the mouths of the various streams are found plaice, kingfish, torpedoes, and cuttle fish. The county has 3 canals: the Great Western, 35 m. long, connecting the S. E. coast with the Bristol channel, the Tamar canal, and the Tavistock canal. The Bristol and Exeter and the South of Devon railways also traverse the county. Devonshire is a rich mineral country, furnishing copper and lead in considerable abundance, with smaller quantities of tin, iron, bismuth, and many other mineral substances, beside coal and marble. It is supposed that the inhabitants worked the iron and other metallic mines before the arrival of the Romans. The tin mines were anciently numerous and valuable, but are now nearly abandoned, those of Cornwall being so much richer. There are several varieties of lead ore, one of which is very rich in silver. Cobalt, antimony, and native silver have been found in considerable quantities. The marbles quarried from the limestone rocks on the E. and S. coasts are of fine colors and beautifully veined, hard, susceptible of a good polish, and much resemble Italian marble. Fine pipe clay, potters' clay, which is exported to other countries, and slate of excellent quality, are found abundantly. The agriculture of Devonshire is in a flourishing condition. Of the 1,654,400 acres of land, about 1,200,000 are under cultivation. The S. and S. E. parts of the county contain extensive wastes, the surfaces of which are covered with immense rocks and detached masses of granite. To the N.

and N. W. are found large tracts of swampy ground and many peat bogs of great depth. The vale of Exeter, containing about 200 sq. m., consists of some very fine land, and is one of the richest valleys in the kingdom. The district called South Hams, extending from Torbay round to Plymouth, is known as the garden of Devonshire, and is finely diversified and very productive. In the vale of Exeter are raised wheat, beans, barley, peas, and flax. The pasture lands are chiefly devoted to dairy uses, though some attention is paid to raising sheep and cattle. In West Devon ⅔ of the enclosed lands are alternated with corn and various kinds of grasses, such as red clover, rye grass, white clover, and trefoil. Irrigation is commonly practised, as also peat burning; orchards and apple trees in hedges are common, and oats, turnips, and potatoes are raised in many districts. The yield of wheat is from 16 to 25 bushels per acre; of barley, from 35 to 50. Devonshire is celebrated for the quantity and quality of its cider. Butter is made in considerable quantities, the average produce of cows being a pound per day. Devonshire cows are noted throughout England, and have been imported into the United States. The purest breeds are distinguished by a high red color, without white spots; they are fine in the bone and clean in the neck, thin skinned, and silky in handling; have horns of medium length bent upward, a small tail set on very high, a light dun ring around the eye, and are noted for feeding at an early age. A good Devonshire cow will yield, for the first 20 weeks after calving, about 3 gallons of milk per day. The cows weigh from 420 to 460 lbs., the oxen from 700 to 820 lbs. The North Devon cattle, another variety, are in great demand for the firm grain of their meat, and the superior qualities of the oxen for work. The native horses are small, but hardy, and much accustomed to the pack saddle. The breed of sheep is various, but mostly of the Dorsetshire kind. Landed property in Devonshire seems to be more regularly divided than in most other counties, there being few very large freeholds; the farms are held generally by leases of 3 lives, or for 99 years. As the lives drop, new ones are put in, on payment of an adequate sum. Farms average from 100 to 200 acres. Devonshire formerly manufactured thin woollen goods, and carried on a considerable woollen trade with Spain, but this branch of industry has greatly declined; the spinning and weaving of a species of serge, known as long ells, being the only remains of it. The spinning of linen yarn, and manufacture of linen goods, have superseded the former industry; also, in and about Tiverton, great quantities of lace and lace net are made, which find a market on the continent of Europe. Ship-building is another branch of labor giving employment to numbers of men. The chief ship yard is the royal dock yard at Devonport. The county contains 33 hundreds, 465 parishes, and 36 market towns. The annual value of real property assessed to property tax, 1850–'51, was £2,736,361. The county town is Exeter, where the assizes are held. The county is in the episcopal see of Exeter, and is included in the western circuit. It returns in all 22 members to parliament, viz.: 4 for the county (2 for the northern and 2 for the southern division), 2 for each of the towns of Barnstaple, Tiverton, Exeter, Devonport, Honiton, Plymouth, Tavistock, and Totness, and 1 each for Ashburton and Dartmouth. It has 1,614 day schools, with 64,266 scholars, and 772 Sunday schools, with 58,408 scholars; 1,297 places of worship, of which 549 belong to the established church. The county gives the title of duke to the Cavendish, and of earl to the Courtenay family. There are ancient ruins in various parts of the county, among which are several abbeys, and numerous old British cairns. The chief noblemen's and gentlemen's seats are Castle hill, seat of Earl Fortescue; Stover lodge, that of the duke of Somerset; Endsleigh, of the duke of Bedford; Saltram, of the earl of Morley; Mount Edgecumbe, of the earl of Mount Edgecumbe; Bagtor manor, of Lord Cranstoun; Exeter palace, of the bishop of Exeter; Bicton, of the late Lord Rolle; Haldon house, of Sir L. Palk, bart.; and Escot, of Sir J. Kennaway, bart.

DEVRIENT, the name of a distinguished family of German actors, of whom the most eminent are: I. Ludwig, born in Berlin, Dec. 15, 1784, died Dec. 30, 1832. His father, a silk mercer, intended him for a mercantile life, but in obedience to his instincts he forsook the paternal mansion at the age of 18, joined a company of strolling actors, and made his first appearance upon the stage in Schiller's "Bride of Messina." He afterward travelled with the same company through Saxony, and in 1806 accepted an engagement at the court theatre of Dessau, from which he was tempted to retire on the promise of his father to pay his debts if he would renounce the stage. Devrient, however, rejected the offer. Soon after the demands of his creditors compelled him to take refuge in Breslau, where he acted with great success for several years. At the suggestion of the actor Iffland, who at the close of his career recognized in Devrient a fit successor to himself, he was induced to go to Berlin, where in 1815 he appeared for the first time as Franz Moor, in Schiller's "Robbers." From that time until his death he stood at the head of his profession in Germany, and was in the highest degree popular with Berlin audiences. A fatal passion for spirituous liquors, which he had indulged for many years, brought him to a premature grave. Devrient was not less esteemed for his amiable and almost childlike character than for his histrionic powers. His eminence as an actor was the offspring of his natural genius, rather than the result of study or reflection. He was equally great in comedy and tragedy. He was married at the outset of his career, but left no children. II. Karl August, nephew of the preceding, born in Berlin, Aug. 5, 1798. He served in a regiment of hussars, in the campaign

of 1815 against France, and was present at the battle of Waterloo; was afterward engaged in mercantile pursuits, and in 1819 made his début on the stage at Brunswick. In 1823 he was married to the celebrated singer, Wilhelmine Schroeder, from whom he was divorced in 1828. He has acted in all parts of Germany, but for many years past has been established at Hanover. He was long celebrated for his spirited personation of leading parts in genteel comedy. III. Philipp Eduard, brother of the preceding, born in Berlin, Aug. 11, 1801. He commenced his artistic career as a bariton singer, but afterward appeared almost exclusively in the spoken drama. He has less natural genius than any of his family, but is a careful and cultivated actor, a successful writer of dramas, and an authority on all that pertains to the profession. His chief works were published in 6 vols., in Leipsic, in 1846–'9, under the title of *Dramatische und dramaturgische Schriften*, and include several plays, miscellaneous publications relating to the stage, and a history of the drama in Germany. IV. Gustav Emil, brother of the preceding, born in Berlin, Sept. 4, 1803. Like his two brothers and his uncle, he was intended for the mercantile profession; but an irresistible inclination led him in 1821 to the theatre, where he soon rose to great eminence. He is well known on almost every stage in Germany, and has assumed with success many of the parts, both in tragedy and comedy, with which his uncle Ludwig's name is identified. His wife, Dorothea Boehler, from whom he was divorced in 1842, was an excellent comic actress, and ably seconded her husband for many years. On Nov. 11, 1857, the 98th anniversary of Schiller's birthday, 3 members of the Devrient family, Gustav Emil, Karl August, and Karl's son, appeared together at Hanover, in the play of "Don Carlos." V. Wilhelmine Schroeder Devrient, a well-known singer on the German stage, born in Hamburg, Oct. 6, 1805. From her mother, the celebrated actress Sophie Schroeder, she inherited considerable dramatic talent, and in 1820, having from the age of 5 upward distinguished herself in children's parts, and in the *corps de ballet*, she appeared in Vienna as Aricie in Schiller's translation of the *Phèdre* of Racine. She soon after devoted herself to the study of music, and in 1821 made her début as Pamina in Mozart's *Zauberflöte*. The beauty of her voice, her artistic skill and dramatic powers, soon placed her in the first rank of German *prime donne*, and for many years she had no superior on the German stage in such parts as Donna Anna in *Don Giovanni*, Leonora in *Fidelio*, the *Vestale* in Spontini's opera of that name, the *Euryanthe* of Von Weber, and others of a similar character. She has also sung in Paris and London, but her chief laurels have been gained in Germany. She was married in 1823 to Karl August Devrient, was divorced from him in 1828, and in 1850 contracted a second matrimonial engagement with a Livonian nobleman, named Von Bock.

DEW, the humidity of the air deposited on surfaces with which it comes in contact. The atmosphere always contains within it more or less aqueous vapor in an invisible form. The vapor appears to be dissolved in it, as salt is held dissolved in clear sea water; and as the capacity of a fluid to hold salts in solution depends commonly on its temperature, so does that of the air to retain vapor. If the temperature be depressed, the vapor begins to appear. When a body of warm air strikes the summit of a cold mountain, the moisture is precipitated in the form of rain. Partially cooled, it takes the form of mist or fog, and floats in a dense cloud in the low places where the soil is warmer than the air. A current of warm air dissolves the vapor, and the fog "lifts." Dew is the vapor of the air, extracted by the greater chilliness of the surfaces upon which the moisture is deposited. It may be made to separate from the apparently dry air of a warm room, by placing in it a pitcher of cold water. The air in contact with the pitcher sheds its moisture, which collects in minute drops, and more is added from adjoining strata of air, so long as the temperature of the pitcher is kept sufficiently below that of the room. The degree of temperature to which the air must be reduced for it to begin to deposit its moisture, is called the dew point. It varies with the greater or less quantity of moisture which the atmosphere happens to contain for its actual temperature. If it has just been deprived of a considerable proportion, and has acquired a higher temperature, it must be reduced to as great a degree of cold as before to part with any more moisture; but if already saturated with as much moisture as it can contain at its temperature, any chilliness being induced will cause its precipitation to commence. Dew is not therefore, as it has been generally described by poets, a shower "which falls like gentle rain from heaven." Almost universally its nature has been misconceived. Horace speaks of *rores pluvii;* Virgil says: *roranti a vidimus astra;* and Pliny: *cum ros cecidisset;* and our common form of expression at this day speaks of the dew drops. Aristotle alone appears to have conceived its true nature, when he describes it as the moisture separated from the cold air. Mysteriously appearing upon the blades of grass, and refreshing the vegetation in climates where rain rarely if ever falls, and gathering upon the herbage in sparkling beads, while it avoided the barren and rocky surface, the simple peasant might well look upon it as a special blessing sent like manna direct from heaven, and possessed of wonderful virtues, far transcending those of other crystal waters, however pure. Hence it came to be prescribed for restoring to the features the fresh charms of youth, and by the alchemists to be used in their processes as a solvent of subtle and mysterious powers. And when at the close of life the ancient patriarch confers his blessing in the words: "God give thee of the dew of heaven," the simple dew drop seems to typify all heaven's choicest gifts. The phenomena attending the

production of dew were imperfectly comprehended previous to the researches of Dr. Wells, and the publication in 1814 of his essay upon the subject. This treatise, pronounced by Dr. Thomson to be "one of the most beautiful examples of inductive reasoning in the English language," presents in clear form the various phenomena as observed by him for two successive years in the vicinity of London. The observations are criticized by Sir John Leslie for want of address and delicacy in the experiments, and omission to make use of the hygrometer and pyroscope; and he expresses much regret that Dr. Wells should have sought to explain the production of the cold by the aid of the "very loose, cumbrous, and visionary hypothesis of M. Prevost of Geneva, concerning what is gratuitously called radiant heat." According to Prof. Leslie, the low temperature of the bodies upon which the dew collects is induced by the descent of cold air, which is precipitated in distinct pulsations, determined by the application of the ætheriscope, by which their intensity also is measured. Two requisites are essential, it appears, for the abundant precipitation of dew; one is the saturation of the atmosphere with moisture, and the other a chilled surface to condense it. The atmosphere is likely to contain the most moisture for its temperature after rains, when the air is cooled, and abundant evaporation is going on from objects upon the surface, and through the pores of the soil. This evaporation tends to chill the surfaces from which it is taking place, and the blades of grass and all shrubs and light bodies near the ground assume a much lower temperature than that of the air above them. Dr. Wells states that this difference of temperature between the grass and the air 4 feet above the ground amounts in clear and still nights to 8° or 9°, and in one instance he observed a difference of 14°; but in cloudy nights the grass was sometimes as warm as the air. Bodies of a filamentous structure, like cotton, flax, hair, silk, gossamer, &c., and of a downy nature, as swan's down especially, are particularly subject to be thus affected, and the deposit of dew first takes place upon them. Each growing plant has its own peculiar power of condensing moisture, which is no doubt proportioned to its requirements of this refreshing agent. When the rays of the sun cease to strike directly upon the surface, the dew-gathering objects soon manifest the want of that temperature which during the heat of the day had kept them above the dew point. If no wind is stirring to mix the air and produce uniformity of temperature, the blades of grass may exhibit moisture upon their surface before the sun has reached the horizon, and soon after having passed it drops are likely to collect. If it be a cool night of spring or autumn, succeeding a hot day, the deposition of dew is likely to increase as the night becomes colder; and in the latter half more is precipitated than in the early part of the night. Should clouds gather, the process ceases, these seeming to reflect the heat that radiates from the surface, and turn it back, so that the requisite difference of temperature between the surface and the air can no longer exist. Any other overshadowing object, as a tree or a bush, has the same effect as the cloud; and the gardener, fearing that when the dew is changed to hoar frost the results of this radiation may reach upon the plants the freezing temperature, throws over them a thin sheet or mat, which retains the radiating heat as it is retained by a cloud. Numerous observations have been made upon the relative capacity of metals and other substances to receive dew. It is probable that they may be arranged in the same order as that which would represent the relative rapidity at which they would be cooled down when exposed under a clear sky. This rate of cooling would evidently vary in the same substance according to its structure and the smoothness or roughness of its surface. Twigs and bushes change their temperature much more rapidly than the same material would in a solid block. The polished surfaces of metals receive less dew than other substances; and bodies laid upon them lose in part their capacity for receiving this deposit by reason of the contact. Probably the worst conductors of heat as a general rule, other circumstances of texture, smoothness, &c., being the same, receive the most dew. It is deposited freely upon glass. The electrical condition of these objects has no influence upon their collecting dew. The quantity of dew which has gathered in a single night has been so great, that it could be determined by the rain gauge. Dr. Dalton estimates the amount precipitated annually in England to be 5 inches. In some countries it is so copiously produced, that the want of rains such as fall in other regions is not seriously felt by the vegetation. Along portions of the western coast of both North and South America rain clouds are rarely seen in many years; the Cordilleras have stripped the air passing over them in the trade winds of nearly all its moisture, and the pleasantly cool and clear nights along the Pacific coast are particularly favorable for the deposition of dew. In the dry regions of Palestine, according to Maundrell, the dew gathering upon the tents wets them as if it had rained all night. The great deserts alone receive no moisture by rain or by dews. Their heated surface presents no cool object to arrest any vapor that may pass over it; and the fall of the temperature of this surface can rarely reach a point at which the little moisture contained in the air above could be so condensed as to saturate it. The vapors of the Mediterranean may be swept by the Etesian winds over the sandy plains of Sahara, but the clouds are no sooner touched by the burning rays reflected from these than they disappear like the morning mists before the rising sun.

DEW, Thomas Roderic, an American writer on government, history, and political economy, born in King and Queen co., Va., Dec. 5, 1802, died in Paris, France, Aug. 6, 1846. He was

graduated at William and Mary college, and began the study of the law; but his health failing, he spent 2 years in the south of Europe, in the autumn of 1827 was elected professor of political economy, history, and metaphysics in William and Mary college, and in 1836 was made president of that institution. In 1829 he published his "Lectures on the Restrictive System," which had been delivered before his college class. It was brought out at a moment when feeling ran high on the subject of the tariff, between protectionists and free-traders; and though emanating from the closet of a thinker removed from the agitations of political warfare, it took a strong hold on the public mind, and the subsequent adoption of the compromise of 1832 may be attributed in part to its silent influence. About the same time, a serious, and it was thought at first alarming rebellion of the slave population was quelled in Southampton co., Va. So great were the terrors inspired by this event, that, combining with a preëxistent desire to abolish slavery on the part of the leading men of the commonwealth, they led to an able and protracted debate in the Virginia legislature, in which the diversity of sentiment was by no means so great upon the policy of emancipation as with respect to the mode in which this should be effected. At this juncture, Mr. Dew's essay on "Slavery" appeared. The change of opinion it brought about was extraordinary and instantaneous. Whatever may be thought of the positions taken by the writer, it must be admitted by all that he sustained them with great ability, and it is certain that the essay set at rest, at that time, the question of emancipation in Virginia. Mr. John Quincy Adams declared that this essay inaugurated a new era in the history of the country, and it is believed that the pro-slavery doctrines now so generally entertained in the southern states of the Union are chiefly due to the moral weight of the novel argument in favor of domestic servitude. When the "Southern Literary Messenger" was established in the year 1834, Mr. Dew became one of its regular contributors, and published in its pages a series of papers on the distinguishing characteristics of the sexes, which attracted much attention. But his most elaborate work was published in New York, in 1853, 7 years after his death, under the title of "A Digest of the Laws, Customs, Manners, and Institutions of the Ancient and Modern Nations." It was modestly called by the author "Notes on History," and had been previously printed in sheets, though in an unfinished state, for the use of his classes in college. It is a treatise on the history of the world from the earliest ages down to the first French revolution, and deals more with the philosophy of history than the mere relation of events, but it exhibits all the best traits of the author's mind. In person, Mr. Dew was tall and lithe, his temperament was nervous, and his movements were somewhat awkward and constrained; yet in the social circle he was always eagerly welcomed for the richness and variety of his conversation. In the summer of 1846 he married, and immediately afterward embarked with his bride for a short European tour. He lived only to reach Paris, and died there suddenly on the night of his arrival. His remains repose in the cemetery of Montmartre.

DEWEES, William Potts, an American physician, professor of obstetrics and diseases of women and children in the university of Pennsylvania, born at Pottsgrove, Penn., May 5, 1768, died in Philadelphia, May 18, 1841. His great-grandfather, who was a Swede, was one of the early settlers on the banks of the Delaware river, before the arrival of William Penn. The father of Dr. Dewees died while the subject of this notice was yet young; and being left without any pecuniary means, he was emphatically the architect of his own fortune. He attended several courses of lectures at the university of Pennsylvania, and in 1789, without taking any formal degree, commenced the practice of medicine at Abington, Penn. The degree of M.D. was at a subsequent period conferred on him by the university. The yellow fever, which visited Philadelphia in the summer and autumn of 1793, having sadly thinned the ranks of the physicians there, in December of that year Dr. Dewees resolved upon selecting this new and enlarged field for his labors. Here he achieved for himself a high and enduring reputation, more especially in that important department to which he devoted particular attention, midwifery, previously much neglected in America. To no one in this country is the medical profession more indebted for its progress in this branch of the science than to Dr. Dewees. In 1812, being threatened with a pulmonary affection, he relinquished the practice of his profession, and for the 5 subsequent years devoted himself to the severe physical labor of agriculture, at Phillipsburg, Penn. In 1817, however, he returned to the field of his former triumphs. Subsequently he published "Inaugural Essays," "Medical Essays," "System of Midwifery," of which latter 12 editions have been printed; in 1825, "A Treatise on the Physical and Medical Treatment of Children," and in 1826, "A Treatise on Diseases of Females," of which 2 last named volumes 10 editions have been printed. His last systematic work was his "Practice of Medicine," which was published in 1830. In 1826 he was elected adjunct professor, and in 1834 professor of obstetrics and diseases of women and children in the university of Pennsylvania. In this latter year, although attacked by paralysis, he was not prevented from delivering the full course of lectures for the season of 1834–'5. At the commencement of the following year he was obliged to resign, and to seek a more genial climate. After spending one winter in Cuba, and the following summer in the North, he settled in Mobile. About a year before his death he returned to Philadelphia, where he resided when he died.

D'EWES, Sir Symonds, an English antiquary, born in Coxden, Dorsetshire, Dec. 18, 1602, died April 18, 1650. He was admitted to the bar, but never practised law, and lived on his property at Stow Hall, in Suffolk. He was high sheriff of Suffolk in 1639, and was one of the Puritan members expelled from the house of commons by "Pride's purge." He commenced collecting materials for a history of England at the age of 18, and though the fruits of his research were not published by him, they were of great use to Selden and other writers. After his death a valuable compilation of his was given to the world by his nephew Paul Bowes, under the title of "The Journals of all the Parliaments during the Reign of Queen Elizabeth" (folio, London, 1682). His "Autobiography and Correspondence," edited by J. O. Halliwell (2 vols. 8vo., London, 1845), contains some interesting pictures of his times and contemporaries, intermixed with much that is useless and with a comical display of vanity.

DE WETTE, Wilhelm Martin Leberecht, a German theologian and biblical critic, born at Ulla near Weimar, Jan. 14, 1780, died at Basel, June 16, 1849. Having studied at Weimar and Jena, he was appointed professor of philosophy, and subsequently of theology, at Heidelberg, and received in 1810 a professorship at the university of Berlin. This situation he lost in consequence of a letter of consolation written to the mother of Sand, the murderer of Kotzebue, which was regarded by the government as extenuating this act of political fanaticism. He retired to Weimar, and was afterward elected professor of theology by the university of Basel. Here he met with an undisturbed acknowledgment of his merits, was made citizen of Basel, member of the committee of education, and shortly before his death rector of the university. De Wette distinguished himself by his lectures and sermons as well as by numerous works. The latter belong to the most remarkable productions of German theological science and criticism. The most important of them are: "Contributions to an Introduction to the Old Testament" (2 vols., 1806–'7); "Commentary on the Psalms" (1811); "Manual of Jewish Archæology" (1814); "Religion and Theology" (1815); "Christian Dogmatics" (2 vols., 1813, 1816); "Critical and Historical Introduction to the Old and New Testaments" (1817–'26; the Introduction to the Old Testament was translated and enlarged by Theodore Parker, Boston, 1843, 2d ed. 1858; and that to the New, by Frederic Frothingham, Boston, 1858); "Christian Morality" (3 vols., 1819–'21); "Theodore, or the Sceptic's Conversion" (1822; translated by James F. Clarke, Boston, 1841); "Lectures on Practical Ethics" (1823; translated by Samuel Osgood, Boston, 1842); *Opuscula Theologica* (1830); "The Essence of Christian Faith" (1846); a new translation of the Bible, executed together with Augusti in 6 vols. (1809–'14); and an unfinished edition of Luther's works.—Ludwig, son of the preceding, born at Berlin about 1814, published a "Journey through the United States and Canada in 1837" (Leipsic, 1838).

DEWEY, Chester, D.D., LL.D., an American clergyman and teacher, born at Sheffield, Mass., Oct. 25, 1784. He was graduated at Williams college in 1806; studied for the ministry; was licensed to preach in 1808, and during the latter half of that year officiated in Tyringham in western Massachusetts. The same year he accepted a tutorship in Williams college, and in 1810 was appointed professor of mathematics and natural philosophy, an office which he discharged for 17 years. During his connection with the college he did much to advance the standard of scholarship, and enlarge the course of study in his own and kindred departments. Over the students his influence was often beneficially exerted. Between 1827 and 1836 he was principal of the "Gymnasium," a high school for boys in Pittsfield, Mass., and in the latter year he removed to Rochester, where he was principal of the Rochester collegiate institute until 1850, when he was elected professor of chemistry and natural philosophy in the university of Rochester, which position he still holds. Professor Dewey has been a frequent contributor to the "American Journal of Science and Arts," and is the author of several special botanical treatises, including a "History of the Herbaceous Plants of Massachusetts," written for the state government. Until recently he has been in the habit of employing his vacations in lecturing at the medical colleges of Pittsfield and Woodstock, Vt. In the course of his long career as a teacher of youth he has delivered over 4,000 lectures, and preached nearly as many sermons. He has effected much for the advancement of public schools, and was active in the establishment of the "Teachers' Institute," of which he has been president.

DEWEY, Orville, D.D., an American clergyman, born at Sheffield, Mass., March 28, 1794, was graduated at Williams college in 1814; pursued his divinity studies at Andover theological seminary from 1816 to 1819; preached 8 months as agent for the American education society; declined an immediate and permanent settlement on account of unfixed opinions in theology, but accepted a temporary call at Gloucester, Cape Ann (with a candid explanation of his unsettled views), and here became a Unitarian; soon after became an assistant of Dr. Channing, preaching two years in his pulpit, and forming with him a life-long intimacy; in 1823 accepted the pastorate of the Unitarian church in New Bedford, where he remained 10 years, until, broken in health, he sought restoration in his first voyage to Europe, June, 1833. The "Old World and the New" (2 vols., 1836), one of the freshest and most instructive records of travel, contains the history of his two years' absence. In 1835 he was called to the 2d Unitarian church in New York, which, during his ministry, built the "church of the Messiah," and became a very large and prosperous society. In 1842, his health

again failing, he went abroad for two years, and returning in 1844 to his post, was compelled by continued ill health to dissolve his connection with his church in 1848, and retire to his paternal farm in Sheffield, long and piously preserved by him, at great sacrifices, for the use of his mother and sisters. Here he devoted the remnants of his strength to the preparation of a course of lectures for the Lowell institute at Boston, on the "Problem of Human Life and Destiny," which was repeated twice in New York, and in Brooklyn, New Bedford, Baltimore, Washington, Charleston, St. Louis, Louisville, Nashville, Madison, Cincinnati, and Sheffield. This course was followed, in 1855, by another Lowell course on the "Education of the Human Race," which was almost as widely repeated. Meanwhile he filled the Unitarian pulpit in Albany one winter, and in Washington two. In 1858 he was again settled as pastor over the Unitarian society in Church Green, Boston, known as the "New South," where he now is. The first book which Dr. Dewey published was a little work, which made a noise in its day, entitled "Letters on Revivals." During his ministry at New Bedford he contributed much to the "Christian Examiner" and the "North American Review." On leaving New Bedford, he published a volume of sermons, which produced a marked sensation. His various works since have been collected and published in 3 vols. (New York, 1847). They consist of "Discourses on Human Nature," "Discourses on Human Life," "Discourses on the Nature of Religion," "Discourses on Commerce and Business," "Miscellaneous and Occasional Discourses," "The Unitarian Belief," "Discourses and Reviews," including several articles which first appeared in the "Christian Examiner." His works have been reprinted in London, 1844, in an octavo volume of nearly 900 pages.—The application of religion to the whole sphere of human life is the characteristic of Dr. Dewey's writings, and the central purpose of his mind. For this work he is admirably fitted both by native endowment and the discipline of experience. His writings exhibit a philosophical tendency, much practical knowledge, wide and lively sympathies, and rare dramatic talent. As a pulpit orator, he enjoys a high reputation for earnestness, originality, and power of impression.

DE WITT. I. A S. E. co. of Texas, drained by the Guadalupe river; area, 898 sq. m.; pop. in 1858, 3,786, of whom 1,189 were slaves. It abounds in fine scenery, and has a hilly or rolling surface. The soil, particularly in the valley of the Guadalupe, is fertile. In 1850 it produced 547 bales of cotton, and 67,560 bushels of corn. Value of real estate in 1858, $545,000. The county was named in honor of De Witt, an empresario under the Mexican government of what was called De Witt's colony. Capital, Clinton. II. A central co. of Illinois, mostly level, comprising forests of valuable timber and fertile prairies, remarkably easy of cultivation; area, 675 sq. m.; pop. in 1855, 18,508. In 1850 the productions were 704,600 bushels of corn, 22,401 of wheat, 45,737 of oats, 2,083 tons of hay, and 18,833 lbs. of wool. There were 6 churches. Bituminous coal is the chief mineral product. The county was named in honor of De Witt Clinton. Capital, Clinton.

DE WITT, Jan, a Dutch statesman, born in Dort, Sept. 1625, murdered at the Hague, Aug. 20, 1672. From his father, who had been a member of the states of Holland, he inherited republican principles opposed to the power of the house of Orange, which had been regarded with suspicion from the time of Barneveldt. In 1652 he became grand pensionary of Holland, an office which gave him great influence in the federal assembly of the Seven United Provinces; and he immediately exerted himself to break up that combination of offices in the hands of the princes of Orange, which had made their power almost sovereign. The last stadtholder had died in 1650, and his son, afterward William III. of England, was an infant; and at this favorable time the party of De Witt succeeded in abolishing the office of stadtholder, and declaring the states-general supreme. In 1654 he negotiated the peace of Westminster with Cromwell, by a secret article of which the members of the house of Orange were in future excluded from the highest offices of state. After the restoration of Charles II., England declared war against Holland; but though her arms were at first successful, the sagacity of De Witt restored the fortunes of his countrymen, and obliged her to sue for peace. The negotiations were hastened by the appearance of De Ruyter with a powerful fleet in the Thames, where he burned the English shipping in the Medway; and a treaty was concluded at Breda in July, 1667. When the aggrandizing policy of Louis XIV. began to aim at the possession of the Spanish Netherlands, De Witt became obnoxious to a strong party in the state, which sought to elevate William of Orange to the dignity of his ancestors. He hastened to form a triple alliance with Sweden and England, but violated the federal constitution by causing the treaty to be at once ratified by the states-general, instead of being first referred to the council of each province. Though the measure may have been justified by the emergency, it was a principal cause of the hostility to De Witt. Louis XIV. succeeded in detaching England from the alliance, and in forming a counter alliance between England and France against Holland; and in 1672 the United Provinces were invaded by French armies, which advanced nearly to Amsterdam. The blame was thrown on the grand pensionary; and by the popular voice the young prince of Orange was called to command the Dutch forces by land and sea, and was nominated stadtholder. Cornelius, the brother of Jan De Witt, was suspected of having plotted against the life of the prince, and was imprisoned at the Hague. The grand pensionary resigned his office, went to visit his brother, and perished with him by the violence

of a mob. His abilities and exemplary private character were applauded even by his political opponents. His principal political work, on the "True Interest and Political Maxims of the Republic of Holland," was translated into English by Dr. Campbell (London, 1746).

DEXTER, Samuel, an American statesman and jurist, born in Boston in 1761, died while on a journey at Athens, N. Y., in 1816. He was graduated at Harvard university in 1781, with the highest honors of his class, and received in 1813 the degree of LL.D. from the same university. Immediately after leaving college he began the study of law, and being admitted to the bar in 1784, after some years of practice in Lunenburg, in Chelmsford, in Billerica, and in Charlestown, he removed to Boston, and had his home there during the remainder of his life. He was repeatedly chosen to the legislature of Massachusetts, and in 1798 was elected senator of the United States. While senator he was appointed secretary of war by John Adams in 1800, and in the same year secretary of the treasury. He was afterward, at different times, offered foreign missions, but always refused them. About the year 1802 he withdrew from political life, and returned to his profession; and there he occupied a high, and in some respects the highest place. He was not regarded as a man of extensive professional learning, or as eloquent in the ordinary sense of that term; but he was well acquainted with the leading principles of law, and possessed the faculty of learning rapidly and well all that was needed in any particular case, by study *in rem*. While he seldom indulged in figures or ornaments of any kind, his powers of argument were almost irresistible. He was often spoken of as "the lawyer for desperate cases," because no case seemed desperate in his hands. As a politician he was in early life a decided federalist; and he never approved all the principles or doings of the republican party of that day. He argued against the validity of the embargo with all his strength, and always maintained the unconstitutionality of that measure. But, on the other hand, he differed from his party in reference to the war of 1812. While, however, he left his own party, he could not be said to have joined the other; and when they nominated him as the republican candidate for governor, in 1814, he immediately published an address to the electors of Massachusetts, in which he declared that he did not belong to the party which had nominated him, and differed radically from them. He was, however, retained as their candidate; and his competitor, Gen. Brooks, the candidate of the federalists, was elected by a majority of only 2,000 out of 47,000 votes. He was the first president of the first society formed in Massachusetts for the promotion of temperance.

DEXTRINE, also known as British Gum, a soluble variety of starch, obtained by boiling starch in water, or heating it to the temperature of 392°, or by the action upon it of diastase or acids. In the malting of grain it is produced with the forming of the sprout, the diastase and acetic acid first appearing, and then converting the starch of the grain into dextrine, from which it passes into sugar, and this into alcohol. When starch is boiled to produce this gum for stiffening linens, its change into sugar may be effected by continuing the boiling. No change in the chemical composition takes place in this process, but the alteration is probably in the arrangement of the particles among themselves. In both starch and dextrine the constituents are, carbon 12 atoms, and hydrogen and oxygen 10 atoms each. Grape sugar, into which they pass, differs from them only by taking another atom of hydrogen and oxygen, or, what is the same thing, one atom of water. Dextrine forms a mucilaginous solution with hot or cold water, from which it is precipitated by alcohol. It is prepared in France to considerable extent from potato starch, to be afterward fermented and converted into brandy. It is also used by the French pastry cooks and confectioners. In medicine it may serve the same uses as gum arabic, and in surgery it is applied to the preparation of bandages for fractures. For this purpose it is triturated with $\frac{2}{3}$ of its weight of camphorated spirit, till it acquires the consistency of honey. Water is then added, and the bandage is immersed in the mixture. As British or "artificial" gum, it is employed by the calico printers for thickening their colors. It is sold in the form of a brilliant white powder, as a mucilage, and in lumps like those of natural gums. Its smell and taste of potato oil distinguishes it from gum arabic, and it differs from natural gums in not forming mucic acid by the action of nitric acid, and in being convertible into grape sugar. The name is derived from its property of turning more than any other body the plane of polarization to the right hand side.

DEY, in Algiers, from 1600 to 1710, the commander of the armies of the state, subject to a pasha appointed by the Porte. In 1710 the dignity of pasha was united with that of dey, and the dey was the highest officer of Algiers from that time till the conquest of the country by the French in 1830.

DEYRA DOON, or Dehra Doon, a fertile valley of British India, between the S. W. base of the lowest and outermost ridge of the Himalayas, and the N. E. slope of the Sewalik mountains, the former having an elevation of 7,000 or 8,000 feet, and the latter of about 3,000; lat. 30° and 30° 32′ N., long. 77° 43′ and 78° 24′ E.; area, 673 sq. m.; length, 5 m.; breadth, from 15 to 20 m. It is bounded S. E. by the Ganges and N. by the Jumna, is drained by their tributaries, and with the hilly region called Jounsar Bawur forms a district under the lieutenant-governorship of the N. W. provinces. The productions are rice, maize, grain, cotton, sugar, opium, indigo, plantain, and hemp. Every English plant is said to thrive luxuriantly, and considerable success has attended the cultivation of tea. The climate during part of the year is

very unhealthy. This district was formerly part of the dominions of the rajah of Gurhwal, was overrun by the Goorkhas in 1803, and in 1815, during the Nepaul war, was invaded by the British, who suffered great loss here, and who, after the expulsion of the Goorkhas, kept possession of the territory.—Deyra, the principal town of the district, is situated in the midst of dense mango groves, at the intersection of 2 routes of trade, 2,369 feet above the sea.

DEZFOOL, Dezful, or Dezphoul, a city of Persia, in the province of Khoozistan, on the eastern bank of a river of the same name; pop. estimated at 15,000. It is the principal mart of the province, and has a fine bridge of 22 arches, said to have been built by command of the celebrated Sapor. About 10 miles S. W. from the city are mounds of ruins which cover the site of the ancient city of Susa.

D'HILLIERS. See Baraguay d'Hilliers.

DIABETES, Glucosuria, Diabetes Mellitus, Glucohæmia (Gr. διαβαινω, to pass through), a disease characterized by an excessive secretion of saccharine urine. Though disease marked by diuresis and attended with wasting of the body was frequently spoken of by earlier authors, Willis (1659) was the first who noted the distinctive character of the complaint, the presence of sugar in that fluid. Since his time diabetes, which is not a very rare complaint, has been frequently made a subject of study, yet still a great deal of obscurity envelops its causes, its essential character, and its treatment. The invasion of diabetes is commonly insidious. The attention of the patient is perhaps first attracted by the quantity of urine he passes and by the frequent calls to void it, or he notices that while his appetite is greatly increased he is growing weaker and thinner. If the urine be now examined, it is found to be not only greatly increased in quantity, but somewhat changed in appearance; it is paler, transparent when first passed, and assumes on standing an opalescent tint like the whey of milk or a solution of honey in water. It has no odor, or a somewhat aromatic one, compared by some to that of new-made hay, by Dr. Watson to that of a room in which apples have been kept. If kept for a few days at a moderately elevated temperature, instead of acquiring an ammoniacal odor like ordinary urine, it has a sharp vinous smell, and will be found to be acid rather than alkaline. The urine has commonly a decidedly sweet taste; drops of it upon the patient's linen or clothes stiffen them like starch, and sometimes leave on evaporation a powdery efflorescence. The specific gravity of the urine is greatly augmented; instead of being from 1.015 to 1.020, as is commonly the case, it ranges from 1.025 to 1.050; M. Bouchardat reports it even as high as 1.074. Two or three simple and easily applied tests are sufficient to render the presence of sugar certain. In what is called Trommer's test, a drop or two of the solution of the sulphate of copper is added to a little of the urine in a test tube; a solution of caustic potash is now added in excess, and the mixture gently boiled over a spirit lamp for a few minutes; if sugar is present, a precipitate of a reddish or yellowish brown (suboxide of copper) will be thrown down, otherwise the precipitate will be black (common oxide). In Moore's test, a little of the suspected urine is mixed in a test tube with about ⅓ its volume of liquor potassæ, and the mixture boiled for 5 minutes; if sugar be present, the fluid will acquire a brown hue, otherwise it remains unchanged. A 3d test is founded on the fact that diabetic urine rapidly undergoes fermentation when mixed with a little yeast and kept in a warm place. The sugar to which diabetic urine owes its peculiar properties exists in the form of glucose or grape sugar. This is present in all proportions, from a mere trace to 30, 50, and even 134 parts in 1,000. The quantity of solid matter thus drained from the system is very great; Dr. Thomas Watson estimates it on the average at 1¼ lbs. per day, but it sometimes amounts to many times this quantity; and it is this drain of solid matter, together with the large amount of urine passed, which gives rise to the constant thirst and the enormous appetite of diabetic patients. Early in the disease, as was before observed, the symptoms are not well marked; when the complaint is established, and the large excretion of urine begins to attract attention, the patient complains that despite his excessive appetite he grows thinner and weaker; the mouth is pasty, the skin dry and hard, the bowels constipated. The digestive functions, at first normal, become deranged; the patient is troubled with heartburn, with a feeling of weight and pain in the epigastrium, sometimes with vomiting. The strength declines, the patient becomes emaciated, the generative functions are impaired or lost; vision often becomes dim, the gums are spongy, there is tenderness and swelling about the orifice of the urethra, the memory and intellect fail, and the temper becomes irritable. In the course of the disease pulmonary consumption is very apt to supervene and carry off the patient. Toward the last, diarrhœa, fetid breath, effusion into the great cavities, and œdema of the extremities, precede death. Diabetes is essentially a chronic disease, lasting often many years; it is also an obstinate and intractable one, although most of the cases seem benefited by treatment, and sometimes it would appear to be completely cured.—*Treatment.* In the beginning of the present century Dr. Rollo found that the amount of urine in diabetic patients as well as its sweetness was very much diminished by confining them to an animal diet. When the ready conversion of starch into grape sugar became known, this was assumed to be the origin of the sugar, and the benefit derived from an exclusively animal diet was thus explained. Unfortunately, few patients have the resolution to restrict themselves for any length of time to such a diet, and even when persevered in it is found to be merely palliative. The experiments of C. Bernard have thrown a new light

upon the subject. He has ascertained that sugar is a normal secretion of the liver in all classes of animals, carnivorous as well as herbivorous; that it takes place in the liver of the fœtus as well as in that of the adult; that irritating the origin of the 8th pair of nerves in the 4th ventricle increases the secretion of sugar, producing an artificial diabetes. In a state of health the normal secretion of sugar poured into the circulation by the hepatic veins is rapidly decomposed and excreted by the lungs; when the amount is increased by disease, the excess passes off by the kidneys. Under the influence of diastase, sugar is likewise formed from the starch of the food in the process of digestion, as a necessary preliminary to its absorption. When diabetic patients are placed upon an animal diet, this source of supply is cut off, and the amount of sugar in the urine is diminished, but it is still present, since the liver keeps up the supply. M. Mialhe, influenced by the theoretic belief that sugar in the course of the circulation is decomposed under the influence of the alkalinity of the blood, and that in diabetes the blood is deficient in alkalinity either positively or relatively to the amount of sugar contained in it, recommends the use of the bicarbonate of soda in large doses. He recommends ½ a dram to be taken 3 times a day, morning, noon, and night; this is gradually increased until from 180 to 270 grains are taken in the course of the day. In addition, the patient is directed to take Vichy water with his meals, and is recommended to drink lime water to the extent of 2 or 3 pints daily. He is permitted to indulge in the ordinary variety in his diet, but the quantity of farinaceæ is reduced ½ or at least ⅓. Flannel is ordered to be worn next the skin; the vapor bath is administered 2 or 3 times a week. By these means M. Mialhe reports a number of cases to have been cured. Dr. A. Clark of New York (New York "Medical and Surgical Journal," Jan. 1859) reports several cases of diabetes either cured or greatly benefited by the use of bicarbonate of soda and of blisters to the nape of the neck. Dr. Clark administered the soda in doses of 11 grains, to be taken as frequently as could be borne until the urine was rendered alkaline or the stomach was nauseated. Beside the alkaline treatment, the means principally relied on have been restricting the quantity of farinaceous matter in the patient's diet as far as possible, indulging him in watery vegetables (spinach, turnips, cabbage, &c.) rather than in bread or potatoes, and the use of opium. This last remedy allays the nervous irritability of the patient, and diminishes the thirst and the amount of the urinary secretion.

DIAGNOSIS (Gr. διαγνωσις, examination, decision), a term in medicine indicating that department of pathology whose object is the distinguishing of diseases by the knowledge of their special pathognomonic signs. To distinguish a disease under all its various forms, and when complicated by symptoms of other affections, is of the first importance in practical medicine, and requires all the acuteness and discrimination of the physician; without a correct diagnosis, treatment must be empirical and hazardous. A mere acquaintance with the symptoms of each disease cannot enable the physician to make his diagnosis. These symptoms are given briefly under the different diseases; diagnosis will be treated here only as a branch of general pathology. Of the symptoms of disease, some are characteristic and pathognomonic, essential and always present; some are common to other diseases, and are of value only when taken in connection with the former class. Examples of the former are the eruptions of the exanthemata, and the mobility of the ends of broken bones; of the latter, the increased frequency of the pulse, heat of the skin, and thirst, common to many different diseased states. A physician must know how to examine and interrogate a patient, to use his own senses of sight, hearing, and touch, to sift the statements of attendants, to weigh justly positive and negative signs; which he can only learn by a knowledge of anatomy and pathology, by experience at the bedside, by an acquaintance with the physiological functions of organs, and by familiarity with the physical examinations of the sick. His fingers must be educated to a sensibility equal to that of the blind man's; his ear, armed with the stethoscope, must hear the first footsteps of disease in the heart and lungs, or the first murmur of life in the gravid uterus; his eyes, assisted by the microscope, must follow the course of morbid growths back even into the primary structure of the cell; he must press, percuss, and measure with the greatest delicacy and exactness; he must be familiar with chemical reactions, in order to detect and neutralize poisons, and arrest the formation of dangerous precipitates in the nutrient and excrementitious fluids. By this manner of interrogating and examining, both by physical and rational signs, every organ and function, the seat, extent, and nature of the disease are ascertained; and it is in making a diagnosis, more than in the treatment, that one physician excels another; for though a blind exhibition of remedies may occasionally be successful in arresting disease, it must be obvious to every reasoning mind that a knowledge of the disease is the first and great essential to its rational treatment. There are many causes which render the diagnosis of disease difficult and uncertain—such as the advanced stage at which many affections are seen; the unusual predominance of certain merely sympathetic phenomena, which mask the primary lesion; the occurrence of new and anomalous types of disease; the complication with other diseases; and the tender age, imbecility, insanity, dissimulation, and deceit of patients. It must be evident from this, what a union of rare faculties and varied acquirements is necessary to enable a physician to make a correct diagnosis of disease; and also that, without this primary result, all speculation as to its progress and termination is mere con-

jecture, and all treatment blind and base empiricism. The French school of medicine is famous for the stress it lays on diagnosis; and students from other parts of Europe, and more especially from the United States, flock to Paris to acquire the elements and practice of this most essential branch of their profession.

DIAGORAS OF MELOS, surnamed the Atheist, a Greek philosopher, lived in the time of Socrates and Aristophanes, but neither the date of his birth nor that of his death is known. He must have removed from his native island to Athens before the performance of the "Clouds" of Aristophanes (424 B.C.), for he is alluded to in that piece as one well known to the Athenians. He was a disciple of Democritus of Abdera. He ridiculed the popular religion, and attacked especially the Eleusinian mysteries, on account of which he was accused of impiety (411 B. C.). Fearing the result of a trial, he made his escape from the city. He was condemned to death by the court, and a price set upon his head. Notwithstanding this, after living for a time at Pallene, he finally died at peace in Corinth. His works are all lost.

DIAL. Sun dials are among the most ancient of human inventions, and, although sometimes said to have been invented in Lacedæmon, were more probably derived by the Greeks from eastern nations. The dial of Ahaz, the king of Judah, is one of the earliest mentioned in the history of the East, and it is probable that the Jews learned the use of this invention from the Babylonians. According to Wilkinson, "there are no indications in the sculptures to prove the epoch when the dial was first known in Egypt." The modern improvements in artificial modes of measuring time are so great, that sun dials are now more a matter of curiosity than of use. They may be divided into 2 essentially different kinds, one of which we may call geometrical, the other algebraical. In order to comprehend the first, we need only observe, that if a rod or gnomon be placed parallel to the axis of the earth, its shadow, conceived of as a sheet of darkness passing in a plane from the rod on the opposite side of the sun, would swing steadily and equally round the rod as a hinge, so long as the sun shone upon it. Upon whatever surface this shadow fell, whether horizontal, vertical, or inclined, its place could be used as a means of measuring time. And if upon this surface lines were drawn, marking the place of the shadow at definite hours of the day, the rod might be made as short as we pleased, reduced indeed to a single ball, held in the place where the extremity of the rod had been, and the shadow of this ball would mark the time upon the lines of the shadow of the rod. The other sort of dial, the algebraical, is more difficult to explain without the use of a diagram. It is drawn upon a piece of card, to which is attached a plumb line with a bead sliding upon it; the card being held in such a manner that the upper edge shall point at the sun, its plane being vertical, the bead marks the hour upon the face of the card. This dial has the advantage of being portable. Dials of the first kind, of a rude nature, may be made portable by having the rod and the dial surface light enough to be balanced upon a compass needle. Beautifully engraved sun dials, for the regulating of clocks, are manufactured by the electrotype process in copper.—The term dial is also applied to any graduated surface, such as a clock or watch face, upon which time is marked out.

DIALLAGE (Gr. διαλλαγη, change, alteration), a mineral of the augite family, so named from its tendency to cleave in different directions. It is a variety of hornblende, in thin foliæ, of various shades of green, gray, brown, and bronze colors, and is found in serpentine and greenstone. Its specific gravity is 3.25. Diallage rock, also called euphotide, is a compound rock of diallage and feldspar.

DIAMAGNETISM. In the native magnet (an ore of iron) a peculiar force resides, which, if a mass of this body be suspended freely, turns or directs it into a line varying slightly from the course of a meridian on the earth's surface. The same end of the magnet being always directed toward the north, this has been termed its N. pole; the opposite, its S. pole. Certain bodies, especially iron, brought near to a magnet, have the magnetic condition induced in them, the extremity nearest either magnetic pole becoming a pole of the opposite name, that most remote a pole of the same name. This result is in accordance with the law that like poles repel, while unlike attract each other. A soft iron bar, around which the electrical current is made to circulate upon a coiled conductor, or helix, becomes magnetic for the time, but loses its magnetism when the current ceases. Small magnetizable particles, as iron filings, dusted upon a surface on which a magnet rests, or agitated near it, become arranged in lines which, between unlike poles that are presented to each other, run across in straight lines, while about these on either side they form curves, making larger and larger sweeps into space. The lines thus indicated have been named magnetic curves, or lines of force. Until recently, the number of magnetic bodies was supposed to be very small. Becquerel, in 1827, found that a needle of wood playing freely on a pivot took a direction across, not in, the magnetic curves; and in 1829 Le Bailli also observed that bismuth repelled the magnetic needle. But the significance of these facts was not understood until an accidental discovery of Faraday, in 1845, led that philosopher into a full investigation of the phenomenon. In the course of his experiments on magnetic rotary polarization, he observed that a bar of so-called "heavy glass," suspended between the poles of an electro-magnet, moved, as soon as by the passage of the electrical current magnetism was induced in the latter, into a position crossing the lines of force, or at right angles to the line joining the poles. Terming the position assumed by a soft iron bar which is lengthwise between the two poles,

or from one to the other, axial, Faraday gave to the new direction assumed by the glass the name of equatorial. The glass was not merely thus directed, it was repelled by either pole; and if, reduced to the form of a small mass or cube, it was thrown out of the line joining the poles to one side or the other, it moved into the position of weakest magnetic action. This new-found property of certain bodies Faraday termed diamagnetism; and in contrast with this, he denominated the familiar form of magnetic action paramagnetism. His experiments warrant the conclusion that, with a sufficiently powerful electro-magnet, all substances whatever can be shown to exhibit one or other of these properties. Liquids and solutions were examined by being suspended in glass vials, the known influence of the glass being allowed for. Among paramagnetic substances, by far the most powerful is iron, then nickel and cobalt, and, in a slight degree, manganese, palladium, crown glass, platinum, osmium, and some others. Vacuum serves as zero in the scale. Then, passing from the less to the more diamagnetic bodies, are found arsenic, ether, alcohol, gold, water, mercury, flint glass, tin, heavy glass, antimony, phosphorus, and, by far the most powerful, bismuth. Flames are diamagnetic, being so strongly repelled by the poles that they divide and pass up on either side, a descending current of air going down in the middle. Most organic substances are diamagnetic; wood, starch, sugar, leather, bread, and even animal tissues and blood, are instances. Oxygen, and perhaps nitrous gas, are the only gases which are known to be ordinarily magnetic; and when it is added that oxygen loses in a degree, though not wholly, its magnetic condition by increase of temperature, it will be seen that the properties of this constituent of our atmosphere probably have important bearings on the production of terrestrial magnetism. Green glass is magnetic in consequence of the iron it contains; and to render wood ordinarily magnetic, it is only necessary to cut a chip of it with a common knife. The magnetic condition of any compound body is found to be determined by what may be called the algebraic sum of the magnetic and diamagnetic powers of its constituents. Thus a compound or solution containing much iron will always be paramagnetic in greater or less degree; but if the iron be blended with comparatively large amounts of water and other diamagnetics, it may be brought to the neutral point, or the compound may be actually diamagnetic. Under all ordinary circumstances, the decidedly magnetic or diamagnetic bodies give to combinations their own character. Another important point is the influence of enveloping material. Certain substances that are repelled, and take the equatorial position in air, are attracted and set axially in water; and even a solution of iron, magnetic in air, if weaker than another solution in which it is immersed, will stand equatorially, and act as a diamagnetic. In terming a body magnetic or diamagnetic, then, we mean that it is such with reference to the medium in which it is tried; and as this medium is commonly air, in which the magnetism of the oxygen dominates over the opposite property of the nitrogen, it is evident that some so-called diamagnetics are only relatively such. With reference to the theory, Faraday now considers that the diamagnet is not rendered polar, as is the magnet, but simply repelled. Prof. W. Thomson has supposed the diamagnet to be simply a body less magnetizable than air, but still polar. In this case it would move away for the more magnetic air, just as in gravitation smoke makes way and ascends above the more strongly gravitating cold air. Plücker, Tyndall, and others adhere to a modified form of Prof. Faraday's earlier view, namely, that the diamagnet is a body susceptible in greater or less degree of a double polarity opposite in character to the double polarity of the magnet; or, in the language of Ampère's theory, that as the currents induced in soft iron are parallel to the currents in the inducing magnet or battery wire, so, in bismuth and other diamagnetics, the currents are induced in contrary directions, so that these bodies become inverted magnets, and place themselves across the magnetic lines of force.

DIAMANTINA, formerly Tejuco, a city of Brazil, and capital of the diamond district, situated in a valley of the province of Minas Geraes, at an elevation of 5,700 feet above the sea; lat. 18° 28′ S., long. 43° 50′ W.; pop. about 6,000. It is built in the form of an amphitheatre, with wide, ill-paved streets, and handsome churches, one of which, belonging to negroes from the coast of Africa, contains an image of a black Virgin. Most of the houses are surrounded by pleasant gardens, and the environs of the city are adorned with orange and banana trees. The climate is mild. The inhabitants are employed chiefly in the gold or diamond trade.

DIAMETER, a straight line passing through the centre of a circle, terminated at each end by the circumference. Straight lines holding an analogous relation to curves, such as the conic sections, are also called diameters of those curves.

DIAMOND (from adamant, and this from Gr. *α* privative and *δαμαω*, to subdue), so named on account of its extreme hardness and indestructibility, a gem distinguished above all other precious stones for its brilliant lustre and hardness. It is met with in solid pieces of small size in alluvial deposits which are worked for gold. In a few instances diamonds have been found attached to loose pieces of brown hematite, and one was discovered in a kind of conglomerate rock, composed of rounded silicious pebbles, quartz, and chalcedony, cemented together by ferruginous clay; but no positive knowledge is had of the particular rock in which they originated, more than that it is one of those belonging to the metamorphic group, which yield gold. In the districts where they occur, a peculiar variety of light yellowish and white quartz rock, of laminated structure, called itacolumite,

is very commonly met with in these rocks. It is remarkable for its flexibility, and the peculiar manner in which the long strips yield to a slight pressure without parting, as if broken in their interior. It is found in Brazil, and in Georgia and North Carolina, in the vicinity of the localities that furnished the few diamonds discovered in these states. In the Golconda district the diamond is found in a black carboniferous boggy earth, in which the natives seek for it by feeling with their feet. The belief is current with them that in this material it grows. In Brazil diamonds have been found massive, in the form of pebbles. Their color is black; specific gravity, 3.012 to 3.416; composition carbon, with sometimes 2 per cent. foreign matter. This quality is valued at 75 cents the carat of 4 grains nearly. The brilliancy and indestructibility of the diamond attracted attention to it at very early periods, and caused it to be highly esteemed as a gem. It was long known in Asia before it was discovered in any other quarter; and the greater part of the supplies have been from that part of the world. Indeed, it was not until the early part of the last century that diamonds were known to exist elsewhere. The mines of Brazil were then discovered, and from 1730 to 1814, according to Baron d'Eschwege, their production was at the rate of 36,000 carats per annum. After 1814 it fell off greatly; but from 1845 to 1858 there has been an enormous increase, the statistics of which have been already furnished in the article Brazil. In the gold region of Siberia a few have been obtained, and within the last 20 years a few also in that of North Carolina and Georgia. In Asia, the most noted localities were the island of Borneo, Bengal, and the famous mines of the kingdom of Golconda in Hindostan. The city of this name was the repository of the diamonds collected in the territory of the kings of Golconda. These mines, celebrated as having produced some of the most valued precious stones in the world, have for some time past been unproductive, and are not now worked.—The diamond is pure crystallized carbon. Its hardness = 10, the highest number of the scale; but the external coat is harder than the internal portion, and may be rated at 10.5 or 11. The following are ascertained specific gravities of different varieties: Brazilian, 3.444; Brazilian yellow, 3.519; oriental, 3.521; oriental green, 3.524; oriental blue, 3.525. The primitive form of the crystal, and that into which the numerous secondary forms may be converted by cleavage, is the regular octahedron, consisting of 2 four-sided pyramids joined at their bases. The faces of the crystals are often rounded off, so as to present a convex surface, and the edges are also often curved. The cleavage planes greatly facilitate the cutting of the diamond, and also present the most brilliant natural surfaces. Some diamonds found of a spherical figure are deficient in these planes, or they lie in a concentric arrangement which renders their cutting almost impracticable by any known process. The diamond is not acted upon by acids or alkalies, and when protected from the action of the air may be heated to whiteness without injury. Exposed to the intense heat produced by a powerful Bunsen's battery, or by a condensed mixture of carbonic oxide and oxygen gas, it fuses, and is converted into a mass resembling coke, and its specific gravity is reduced in some cases to 2.678. Heated in the open air, it burns at the temperature of 14° Wedgwood, or about that of melting silver, and is dissipated in the form of carbonic acid gas, thus proving its composition to be pure carbon. Its inflammability was suspected by Boetius de Boodt in 1607, and in 1673 Boyle discovered that it was dissipated in vapor at a high heat. Its combustibility was first proved by the Florentine philosophers in 1694, by subjecting the gem to the solar rays concentrated in the focus of the large parabolic reflector made for Cosmo de' Medici, when it burned with a blue lambent flame. The experiment has been several times repeated by Sir Humphry Davy with the same speculum, and by Lavoisier, Mr. Tennant, and others, by different processes. Sir George Mackenzie made use of the diamond for furnishing the carbon to convert iron into steel. The property of phosphorescence has been attributed to the diamond after it has been exposed to a heat approaching redness, or to the action of the solar rays, especially the blue rays; and it has been stated that when the phenomenon is produced by the latter method the effect continues some time after the stone is removed from the light. But this is not confirmed by late authorities. Experiments conducted through several months in 1858 at Messrs. Tiffany and company's, of New York, failed to develop any save negative evidence; and when they were renewed in January, 1859, for the purposes of this article, they were abruptly terminated through the carelessness of a workman, by the unfortunate destruction of a valuable gem obligingly lent by them. In no instance did any symptom of phosphorescence appear; but a remarkable increase in refraction was several times observed, and this appeared to be permanent. The diamond possesses single or double refraction according to its different crystalline forms; and it has an extraordinary power of refracting light, the index of refraction being 2.44, which led Sir Isaac Newton to suspect its inflammable composition. The dispersive quality of diamond is high; its index is equal to 0.0109. Its refraction index (exceeded only by that of chromate of lead) equals 2.439; of some brown stones it has been observed to be 2.470, 2.487, and 2.775.—Diamonds are found of various colors, as well as colorless and perfectly transparent. The latter are most esteemed, and are distinguished as diamonds of the first water from their semblance to a drop of clear spring water. When of a rose tint and of clear water, they are also highly valued. A yellow shade is objectionable, as is a cinnamon color, a stone having these rarely being clear and sound. Next to the rose, a green color is the least objectionable; many very fine diamonds have this

tint; and some are found of a bluish color, and some black. For the valuation of diamonds an arbitrary rule has been given, which is, however, little regarded in actual sales of the most costly of these gems. Purchasers for such being few, the only real rule adopted, as in the sale of many other commodities, is to demand the highest price there is the least probability that one may be induced to pay. The mere statement of the rule is sufficient to show its indefiniteness. It is to multiply the square of the weight in carats by a sum varying according to the state and quality of the stone. If clear and of good shape, this sum is £2; if perfect and well cut, £6 or £8 for the brilliant or rose, but a lower figure for the table. The rate is now $15 in place of the £2 above, and a specimen brilliant is worth $75. For diamonds of moderate size the rates vary as little as those of exchange between countries. They follow from the natural proportions in which diamonds are found. Diamonds weighing over 10 carats are generally esteemed at a higher proportional rate than the smaller sizes; yet the latter can commonly be sold at higher proportional rates, on account of the few purchasers for those of large size. In the great sale of jewels in London in 1837, on the distribution of the Deccan booty obtained by the army of the marquis of Hastings, the splendid Nassuck diamond, weighing 357½ grains, and of the purest water, brought only £7,200. The present value of diamonds may be inferred from the price paid in Dec. 1858, for a stone weighing 61 carats, £33,000. A pair of drop-shaped diamonds for ear-rings were bought at the same sale for £15,000. A steady increase has taken place since the last century, and a much more rapid increase in the price of fine gems is to be expected, from the increased demand and diminished supply. It is an interesting fact that the finest gems of commerce are now in great part supplied by the old jewels of Portuguese, Spanish, French, and English families, the proportions from each nation in the order named; and that the best market for them is now the United States.—The art of cutting and polishing probably originated in Asia, at a very early period, but was first introduced into Europe about the middle of the 15th century by Louis Berquen of Bruges, who accidentally discovered that by rubbing 2 diamonds together their surfaces might be abraded. The powder obtained in this way is used for polishing the stone. Diamond cutting was for a long time a monopoly in Holland, and the business is at the present day mostly confined to Amsterdam. The process, which consists of grinding down the surfaces as well as cutting, is slow and tedious, and being done entirely by hand, occupies for a single stone the continual labor of months. The Pitt diamond indeed required 2 years for the completion of the process. Two diamonds are employed, each cemented into the end of a stick or handle, a model in lead being taken of the one to be cut, by which the faces are determined. The stones are then rubbed together with a strong pressure, being held over a metal box having a double bottom, the upper one perforated with small holes, through which the diamond dust falls. This is afterward carefully collected, mixed with vegetable oil, and used for polishing the gem upon a revolving cast-iron disk. When a large piece is to be removed from the stone, it is sometimes cut off by means of a steel wire covered with diamond powder, and sometimes by the use of a chisel and hammer, though in this way there is danger of destroying the stone. The workman should understand perfectly the position of the cleavage planes, as it is only upon them that pieces can be removed by the chisel. The forms usually adopted in cutting the diamond are the brilliant, the rose, and the table. The first shows the gem to the best advantage. It is composed of a principal face called the table, surrounded by a number of facets, which is all that is visible above the bezil when set. The stone in depth below the bezil should be equal to half its breadth. On the under side it terminates in a small table, which is connected with the upper surface by elongated facets. As the brilliant is the most economical of material, and shows the stone most advantageously, it is usually preferred to any other. The rose, which is very brilliant, is flat below and cut into facets entirely over the upper surface. The table is least beautiful, and is used mostly in India for thin stones with a large surface, which are ornamented by being cut into facets at the edges.—Among the most celebrated diamonds known, that obtained by Mr. Pitt, governor of Madras, is perhaps one of the finest and most perfect. It is known as the regent. Its weight before cutting was 410 carats, and by this process, which occupied 2 years, it was reduced to 136 carats, and was purchased by the regent duke of Orleans in 1743 for $675,000. Its present value is estimated at $1,000,000. It was placed by Napoleon in the hilt of the sword of state. A splendid diamond recently found in Brazil, and imported into France, is called the "Star of the South." It weighs in its rough state 254½ carats. Its general form is a rhomboidal dodecahedron, and upon its faces are impressions which appear to have been made by other diamonds, so that the whole was probably a group of diamond crystals. The famous diamond in possession of the king of Portugal is also from Brazil. If genuine, of which there is some doubt, its value, according to the rule of computation, should be $28,000,000, weighing as it does in the rough 1,680 grains.—The famous Koh-i-noor or "Mountain of Light" is now in possession of the queen of England. This wonderful stone, interesting alike for its historical associations and for its intrinsic beauty, was, according to Indian tradition, obtained before the Christian era from one of the mines of Golconda. From the rajah of Oojein, who seems to have possessed it at the beginning of the Christian era, it passed to successive sovereigns of central India, and in the early part of the 14th century was added to the treasures of Delhi by the Patan monarch Aladdin. It remained in possession of the rul-

ing families of the empire until the irruption of the Persian conqueror Nadir Shah, who saw it glittering in the turban of the vanquished Mohammed Shah, and proposing an exchange of head dress as a mark of friendship, bore it away with him, and gave it the name by which it is still known. After the assassination of Nadir it passed through the hands of Ahmed Shah of Cabool to Shah Soojah, who paid it as the price of his liberty to his conqueror Runjeet Singh, the "lion of the Punjaub," in 1813. On the annexation of the Punjaub to the East India company's territory in 1849, it was stipulated that the Koh-i-noor should be surrendered to the queen of England, to whom it was accordingly delivered by the company, July 3, 1850. At this period its weight was 186 carats. It was exhibited at the crystal palace in London in 1851, where it attracted universal attention; but when found to exhibit an inferior display of colors to its glass model, and that it was necessary to surround it with a number of vivid lights to develop its colored refractions, multitudes turned away disappointed from the world-renowned "Mountain of Light." An examination was made of it by scientific gentlemen, with reference to the propriety of recutting the gem. After obtaining the opinions of skilful cutters at Amsterdam, it was decided that the attempt should be made, though some fears were entertained as to its success. Being the largest diamond cut in Europe for a long time, it was a work of no common interest. Orders were given that the proper machinery should be prepared, and a small steam engine was procured for the purpose. The duke of Wellington commenced the work. The stone being imbedded in lead, excepting only that portion which was first to be cut, he held it firmly against a rapidly revolving wheel, which by its friction removed the angle exposed, and thus the first facet of the fresh cutting was accomplished. The operation was continued and successfully completed by careful and experienced workmen. Now, the splendid Koh-i-noor, freed from all blemishes and defects, blazes brilliantly among the crown jewels of the sovereign of England.—The diamond so long in possession of the sultan of Matan, of the island of Borneo, is remarkable for its size and purity. It weighs 367 carats, and should be worth at least $3,500,000. It is shaped like an egg with an indented hollow in the smaller end. It was discovered at Landak. The Orloff diamond purchased for the empress Catharine of Russia is about the size of a pigeon's egg, and weighs 195 carats. It is said to have formed the eye of a famous idol in a temple of Brahma at Pondicherry. A French deserter robbed the pagoda of this valuable stone. After passing through the hands of various purchasers, it came into the possession of a Greek merchant, who received for it from the empress $450,000, an annuity of $20,000, and a title of nobility. The Austrian diamond is of a beautiful lemon color, and cut in rose; its weight is 139 carats. Its value is less than it would be but for its color and the form in which it is cut, ranking as worth $500,000 instead of $750,000. The most valuable diamond found in the United States was picked up by a workman at Manchester, on the banks of the James river, opposite Richmond, in 1856. The locality is in the tertiary formation, and the diamond originally belonged, no doubt, to the gold region up the river. It is of curvilinear octahedral form, specific gravity 3.503, and weighs 23.7 carats. It is lightly chatoyant, and would probably cut white; but an original flaw was increased by the rough treatment it received from those into whose hands it fell, so that its value was greatly deteriorated. It is now in possession of Prof. Dewey. Another valuable diamond, owned by Thomas G. Clemson, Esq., was found among the gold washings of North Carolina about the year 1842. This was of curvilinear form, and was set without cutting. Others of less importance have been found in Georgia.—The imitation of diamonds has been carried to an astonishing degree of perfection among the French. M. Bourguignon has been especially successful in this manufacture. The sand employed for the production of his splendid diamonds is procured from the forest of Fontainebleau, and forms a considerable article of trade. The setting of these mock stones is always of pure gold, and of the newest fashion, and the ornaments when completed rival in delicacy and lustre the purest diamonds which nature has produced, and only by the closest inspection can the difference be detected. The chief objection to them is their liability to become dull in time by deliquescence.—The process of collecting diamonds is similar to that of collecting gold in the alluvial deposits. The coarse gravel and rolled pebbles derived from the primary and metamorphic rocks, form the lowest stratum among the sands and clays of the alluvium. This stratum, resting upon the surface of the rock, is the repository alike of gold and of diamonds. It is laid bare in the beds of the streams, when these cease to flow in the dry season, or are drawn off by sluices made for the purpose. From these beds, as well as from excavations in the bottom, the gravel is removed, to be washed when convenient. This in Brazil is usually in the rainy season, and the work is done in a long shed, through which a stream of water is conveyed, and admitted into boxes in which the gravel is washed. A negro works at each box, and inspectors are placed to watch the work, and to prevent the laborers from secreting the diamonds. It is the custom to liberate the negro who finds a diamond weighing 17½ carats. Dr. Beke, in a paper read at a meeting of the British association, relates that a slave in Brazil seeking for diamonds in the bed of a river broke with his iron bar through a crust of silicious materials, cemented together by oxide of iron, in which he discovered a bed of diamonds, which were afterward sold for $1,500,000. This immense quantity, being carried to England, so

overstocked the market that few of the English houses were able to stand up against it.—Beside their use as ornaments, diamonds are applied to several practical purposes. Those that are unfit from their imperfections for jewelry, are sold under the technical name of bort. They are crushed to fine powder in a steel mortar, and used for coating the metallic disks employed by lapidaries for producing flat surfaces on precious stones of great hardness. The fine splinters are made into drills, for piercing small holes through rubies and other hard stones. The property possessed by the diamond of cutting glass is due not merely to its extreme hardness, but to the peculiarity of its crystallization in rounded faces and curvilinear edges. The natural crystal only is suitable for this purpose. According to Dr. Wollaston, many hard stones, and even flint cut in this form, possess the same property, but soon lose it in use, for want of hardness. Small microscopes of a single lens, and of great power and clearness, have been cut out of diamonds.—The diamond exhibiting the physical properties of matter in their highest state of perfection, and proving after all to be of the simplest chemical composition, it has been a matter of no little scientific interest to study the peculiarities of its construction, and to determine if possible the secret processes by which nature has elaborated the most perfect gem from so homely a substance as charcoal. Its high value has stimulated these researches, in the hope of individual profit by its artificial production. But though more complicated forms of matter have been successfully reproduced, carbon has not yet been made to attain the simple perfection of the diamond, unless it be in crystals invisible to the naked eye; nor have we yet learned from what department of nature's works the material has been taken, that has been so beautifully perfected. The vegetable kingdom may have furnished it, after itself receiving it from the atmosphere, or it may have been unlocked from those repositories of carbon shut up from remote geological periods in the carbonic acid of the calcareous rocks, or from such collections of fossilized plants as are now seen in various stages of change to mineral substance. But if the direct object of these researches has not been attained, the forces which have acted upon it to give to it some of its peculiarities have been partially determined, as also a previous condition in which it must have existed. Sir David Brewster, from the exhibition of polarized light around the minute and irregular cavities in diamonds, has concluded that the substance has once been in a soft state, and compressed in these parts by the expansive action of a gas or fluid contained in the cavities; and as various circumstances indicate that this softness was not the effect of either solvents or heat, he is of opinion that, like amber, the diamond is a vegetable substance, slowly consolidated into a crystalline form. The nearest approach to its reproduction has been in the experiments of M. Desprétz, announced in the year 1853. By long continued voltaic action, carbon free from every trace of mineral substance, prepared from crystallized sugar candy, was made to deposit microscopic crystals in black octahedrons, in colorless translucent octahedrons, and in colorless and translucent plates, the whole of which had the hardness of the powder of the diamond, and which disappeared in combustion without leaving any perceptible residue. Being, however, only in powder, it was impossible to isolate and weigh these crystals, or to determine their index of refraction and angles of polarization. It is said that a similar result has been obtained by decomposing a mixture of chloride of carbon and alcohol by weak galvanic currents.—The principal English works on the subject are D. Jeffrey's "Treatise on Diamonds and Pearls" (8vo., London, 1750); J. Mawe's "Treatise on Diamonds and Precious Stones" (8vo., London, 1826).

DIAMOND DISTRICT, a part of the district of Serro Frio, in the province of Minas Geraes, Brazil, famous for the production of diamonds. It is a mountainous tract, not far from Villa do Principe, extending about 16 leagues from N. to S. and 8 from E. to W. The diamonds were first discovered here by a company of gold miners in 1730. At first they were ignorant of the value of the gems, and threw away many of them as useless. Others were sent to the governor of Brazil, who supposed them to be curious crystals. A few of the stones having been carried to Lisbon were shown to the Dutch consul, who recognized them as diamonds, and had them transmitted to Holland. Immense numbers of the gems were now exported from Brazil, and the Portuguese government soon took measures to secure a monopoly of the valuable trade. The district was surrounded by lines of demarkation, which were guarded with the utmost strictness. No one was permitted to pass these in either direction without a permit from the intendant of the mines, and travellers leaving the diamond ground were obliged to submit to a thorough examination of their persons, baggage, and horses. A peculiar system of police was established for the regulation of the district, and stringent laws were passed to provide for the registering of the inhabitants, the admission of settlers, the erection of inns and shops, and the punishment of infringements of the government monopoly. The diamond mines were at first rented to private individuals, but the frauds and violations of contract of which these persons were constantly guilty induced the government to take the matter into its own hands, and the mines were long worked under the direction of officers of the crown. The precious stones are found in a kind of gravel, called *cascalhão*, which is dug up and removed to a convenient place for washing. A shed, about 25 or 30 yards long and 15 wide, consisting simply of upright posts and a thatched roof, is erected over the spot where the heaps of cascalhão are to be deposited. Through the centre of this shed is conducted a stream of

water, on one side of which is a range of sloping troughs, each about 3 feet wide, and communicating with the stream at the upper end. Opposite to the troughs are high chairs placed at equal distances for the overseers, or *feitores*. A slave stations himself in each trough, and with a short-handled rake draws up a pile of 50 or 80 pounds of cascalhão. He lets in water upon this, to wash away the earthy particles, and after throwing out the largest stones, examines the rest with great care for diamonds. As soon as he finds one, he stands upright, claps his hands, and holding it between his finger and thumb shows it to the overseer, who receives it from him, and places it in a bowl half full of water, suspended from the centre of the structure. The mines are now open to all who choose to invest their capital in them, and the cost of working them has been estimated at about $8 per carat. They give employment and support to about 10,000 persons.

DIAMOND HARBOR, a roadstead in the river Hoogly, presidency of Bengal, British India, 29 m. below Calcutta. It was the first place in Bengal acquired by the East India company, and is now a shipping depot. The climate is very unhealthy; the neighboring swamps exhale the most noxious vapors, and the night dews are remarkably heavy. An excellent road and an electric telegraph connect the place with Calcutta.

DIANA, an ancient Italian divinity, identified by the Romans with the Artemis of the Greeks. Servius Tullius is said to have introduced her worship at Rome, dedicating to her a temple on the Aventine. As goddess of light she represented the moon. The root of her name seems to be the same as that of the word *dies*. In images and legends of a later period she fully answers to the Grecian Artemis. (See Artemis.)

DIANA of Poitiers, duchess of Valentinois, mistress of Henry II. of France, born Sept. 3, 1499, died in Anet, April 22, 1566. She was maid of honor to Queen Claude, and when her father, the count of St. Vallier, had been condemned to death for favoring the escape of the constable Bourbon, she so touched the heart of the susceptible Francis I. by her tears and beauty, that the punishment was commuted. At the age of 13 she became the wife of Louis de Brézé, count of Maulevrier, by whom she had 2 daughters. In 1531 her husband died, and Diana, putting on a widow's weeds, expressed a resolve to wear them to her grave; but this did not prevent her when nearly 40 years old from becoming the mistress of the dauphin, afterward Henry II. The duchess of Étampes then possessed the affections of Francis I., and the 2 favorites divided the court until the accession of the dauphin, when Diana's rival was sent into exile. Diana now became almost mistress of the kingdom. The beauty and accomplishments of the young queen, Catharine de' Medici, could not prevail against her influence. The king delighted in giving public tokens of his infatuation, and not content with wearing her colors and blazoning the palaces and public buildings with her emblems and devices, he admitted her to his councils, and in 1548 created her duchess of Valentinois. She retained her ascendency until Henry's death in 1559, when she retired to the palace built for her by her royal lover at Anet; but in 1561 she was recalled by Catharine de' Medici to exert her influence in detaching the constable de Montmorency from the Châtillons. From that time until her death she remained in retirement, retaining her personal charms, of which she had always taken the most extraordinary care, to the last. Her power over the king, even when she had reached the ripe age of 60, was due no less to her beauty than to her intellectual gifts. She seldom made a bad use of her position, and she spent large sums in charity.

DIAPASON (Gr. δια, through, and πας, all), a term employed by the old Greek and Latin musicians to denote the scale or octave. Modern musicians sometimes employ it in a similar manner. The diapason stops of an organ are so called because they run through the whole register of the keyboard.

DIAPER, a linen fabric, said to have been originally made at Ypres in Belgium, and hence known as d'Ypres, whence its present name. It is distinguished by its flowered patterns, and sometimes resembles damask. It is largely manufactured for napkins, table-cloths, &c. Ireland, Germany, and Scotland especially produce excellent qualities of the article.

DIAPHORETICS, or Sudorifics (Gr. διαφερεω, to carry through), stimulant medicines, which increase the cutaneous transpiration. In this class were formerly included many substances, especially the mints and similar plants, which are only diaphoretic in virtue of the abundant, warm, and watery infusion in which they are administered. There are, however, certain substances, vegetable and mineral, which exert a special action upon the skin, stimulating the sudoriferous glands, and eliminated by the cutaneous surface. Warm water is an excellent diaphoretic, either simple or in the form of the many domestic herb teas; the vapor and warm baths are effectual and natural stimulators of the skin; the cold bath, and the various applications of the hydrotherapic method, are sure but disagreeable and often dangerous sudorifics. Among vegetable remedies of this class are aconite, opium (alone or combined in the form of Dover's powder), dulcamara, guaiacum, sarsaparilla, mezereon, and squill. At the head of the mineral diaphoretics stand the antimonials; others are sulphur and the preparations of ammonia. The ethers, especially the nitrous, are powerfully diaphoretic when the surface is kept warmly covered. Indeed, many of the so-called diaphoretics, if the body be not kept warm, act as diuretics, increasing the urinary secretion; and almost any stimulating medicine will increase the secretion of the skin, if the surface be warmed or prevented from losing its heat by evaporation. Deficient action in the skin is seen in a great variety of complaints,

and in certain stages of almost all fevers, and the choice of the proper remedy to stimulate its action often requires the highest skill of the physician. Diaphoretics are employed to most advantage in chronic diseases of the skin, in gout and rheumatism, syphilis, dropsy, and catarrhal affections. When we consider the amount of carbonic acid and azotized matters thrown off by the skin, in its vicarious and alternating performance of the offices of the lungs and kidneys, we can understand how necessary it is to keep this surface in a healthy condition. The skin is a most important respiratory organ, and will keep up the standard of animal heat when the lungs are almost destroyed as aërating organs, giving a most valuable therapeutic indication in the treatment of pulmonary affections. According to Mr. Wilson, the total number of pores of the sudoriferous glands on the surface of the human body is about 7,000,000, and the length of the perspiratory tubing connected therewith nearly 28 miles. Such an extensive system as this cannot be neglected in disease with impunity, and the medicines which can stimulate it, when depressed or obstructed, must be among the most useful in the materia medica. It is highly probable that, in many forms of fever, the suppression of the perspiration is the cause of the disordered vascular action; and that deficient action of the cutaneous glandulæ, from want of exercise and inattention to cleanliness, is a frequent source of disease, from the accumulation in the blood of decomposing organic matter whose natural outlet is the skin. The cutaneous surface seems to be the natural channel for the elimination of many morbid products, and the use of diaphoretics to be the only rational method of removing such from the system. The experience of physicians in tropical climates shows that the great art of preserving health there consists in attention to the regular performance of the cutaneous functions, and that the adynamic fevers of those unhealthy regions are best treated by active diaphoretics.

DIAPHRAGM, the transverse muscle which separates the thoracic from the abdominal cavity in mammalian vertebrates. It is flattened in shape, nearly circular, fleshy at the edges, tendinous in the centre, elongated, and ending in a point behind. In front it is attached to the ensiform cartilage of the breast bone, on the sides to the posterior surface of the last 6 ribs, behind to the transverse process of the 1st lumbar vertebra and to the bodies of the first 3 vertebræ of the loins by tendinous slips; the fleshy fibres of the last form the pillars of the diaphragm, and their fasciculi cross each other in such a way as to leave 2 openings, one superior and most anterior, giving passage to the œsophagus and par vagum nerve, the other inferior and more to the left, for the passage of the aorta, thoracic duct, and vena azygos; the tendinous centre has been compared to a leaf of clover. Between the middle and right portion of the tendinous centre is the opening for the passage of the inferior vena cava. The diaphragm is in relation, above, with the pericardium in the middle, and with the pleuræ, base of the lungs, and walls of the chest on the sides; below, with the aorta in the middle, the kidneys, renal capsules, pancreas, and duodenum; on the right side with the liver, and on the left with the stomach and spleen. The direction of the posterior fibres is nearly vertical; all the others converge toward the tendinous centre. The diaphragm is the great muscle of respiration; when it contracts, its upward convexity becomes a plane surface, the cavity of the chest is enlarged, and air rushes in to expand the lungs during the act of inspiration; when forcibly contracted, it may act as an assistant to the abdominal expiratory muscles by diminishing the size of the base of the chest; by its action on the abdominal viscera it aids in the expulsion of fæces and urine; in ordinarily tranquil breathing the diaphragm is sufficient for the performance of the function. In animals the extent and position of the diaphragm vary according to the number of the ribs; in those whose ribs extend nearly to the pelvis, as in the horse, the thoracic convexity of the diaphragm is much greater than in man. This important muscle is liable to malformations, wounds, and morbid conditions; its total absence is incompatible with any other than intrauterine life, as aërial respiration would be impossible; its partial absence, like dilatation of its natural openings, or laceration of its fibres, is accompanied by the passage of more or less of the abdominal viscera into the chest, impeding the action of the heart, lungs, and digestive organs; in such cases, the liver, stomach, omentum, ileum, cæcum, and part of the colon, have been found above the diaphragm. This partition is also liable to penetrating wounds, and to rupture from external violence, the latter being the most dangerous; in either case, nature alone can remedy the evil. It is sometimes inflamed, and in the rheumatic diathesis is the seat of the most acute pain, increased by every respiratory act, and forcing the patient to breathe almost entirely by means of the abdominal muscles. Spasmodic contractions are familiarly known by the phenomenon of hiccough; this is sometimes merely a nervous affection, and at others is a symptom of peritonitis, strangulated hernia, and other abdominal diseases. Paralysis of the diaphragm is speedily fatal, from the suspension of respiration.

DIARBEKIR, Diyar-Bekr, or Diarbekr, a town of Turkey in Asia, formerly capital of an ancient pashalic of the same name, on a rocky eminence a short distance from the right bank of the river Tigris, in lat. 37° 55′ 30″ N., long. 39° 52′ E. A fertile and well cultivated plain surrounds the city, which is encompassed by walls pierced by 4 gates, and surmounted by many towers. In the N. E. portion of the town are the ruins of the citadel, formerly the residence of the pasha. The town was once a very flourishing place, and contained, it is said, 200,-

000 inhabitants; but owing to the predatory disposition of the Koords, who by their attacks have rendered unsafe the intercourse with Bagdad and Aleppo, its prosperity has declined, and it now contains no more than 40,000 inhabitants, the greater part Turkish, the rest mostly Armenian. Some trade is, however, carried on with Aleppo, and the manufacture of cotton and silk goods, though much diminished, is still continued. The streets, like those of other eastern cities, are narrow and dirty, and most of the houses are constructed of rough stone covered with a plaster composed of mud and straw. The town contains many mosques, an Armenian cathedral and other Christian churches, numerous baths, caravansaries, and bazaars, and is well supplied with water, which is introduced by a fine aqueduct, and distributed through the city in numerous stone fountains. The walls are built of a dark-colored basalt, quarried in the neighborhood, and many of the principal buildings of the city are constructed of the same material, whence the Turks call the place Kara Amid, or Black Amid; Amida being the ancient name of the town. A British consul resides here.

DIARRHŒA (Gr. διαῤῥέω, to flow through), a disease characterized by the occurrence of frequent, loose, alvine discharges. In a proper system of nosology diarrhœa would scarce find a place; it is a symptom rather than a disease, and is produced by a number of different pathological conditions. It is present in the course of typhoid fever, is a frequent accompaniment of phthisis, and is sometimes an attendant upon albuminuria and other forms of blood poisoning; it is caused by inflammation and ulceration of the bowels. Those slighter forms of the complaint only will be noticed here which are independent of constitutional causes, and which are produced by a temporary irritation or sub-inflammation of the intestinal mucous membrane. Diarrhœa is often caused by the use of crude and indigestible food, or even by food ordinarily wholesome taken in too great quantity or variety. Fruit, particularly when acid and unripe, uncooked vegetables, as cucumbers and salads, food in a state of incipient decomposition, the flesh of immature animals, as young veal, &c., are all liable to act upon the bowels. Certain articles, as mushrooms, shellfish, the richer varieties of ordinary fish, as salmon, from peculiarity of habit disagree with particular individuals and produce diarrhœa. The same is true of a total change of diet; food perfectly wholesome to those accustomed to it, and the water used habitually in certain districts of country, often cause bowel complaints in the stranger. Emotions of the mind, particularly grief and anger, in some persons promptly occasion an attack of diarrhœa; others are affected in the same way by sudden changes of temperature, wet feet, or exposure to cold. Where diarrhœa is caused by the ingestion of food rendered irritating by its quantity or quality, the purging itself soon removes the cause of irritation and the diarrhœa ceases; if this should not be the case, a moderate opiate or an anodyne combined with an astringent are all that will be found necessary. When diarrhœa is dependent on exposure to cold, a bland, unirritating diet, the warm bath, and the use of opium or of opium and ipecacuanha in small doses, may be had recourse to; in such cases the patient is generally benefited by wearing a flannel bandage around the abdomen.—Young infants at the breast sometimes suffer from bowel complaint; here it is commonly caused by over-feeding. Ordinarily nature provides against this by the facility with which the infant vomits; the stomach frees itself from the excess of food, and no mischief is done; but when the infant does not vomit, diarrhœa is caused, and undigested curd is present in large quantity in the evacuations. The obvious remedy is a prolongation of the intervals at which the child is suckled. During dentition in infants, from the large quantity of blood sent to the digestive organs, and the rapid evolution which they are undergoing, the bowels are irritable, and diarrhœa often supervenes; this is best guarded against by care in the diet and a proper observance of hygienic regulations. The severer forms of the complaint which occur in large cities, from the combined effect of an impure atmosphere and the excessive heat of our summers, are spoken of under the head of Cholera Infantum.

DIAS, A. Gonçalvez, a Brazilian poet, born in Caxias, Aug. 10, 1823. He was educated in Portugal, and returning to his native country, published at Rio de Janeiro in 1846 a volume of poems entitled *Primeiros cantos*, which was followed by his drama of *Leonor de Mendonça* (1847), *Segundos cantos* (1848), and *Ultimos cantos* (1850). In 1848 he was chosen professor of national history in the college of Don Pedro II.; in 1850 he was sent on a scientific mission to the provinces bordering on the Amazon; on his return he was employed in the office of the minister of foreign affairs, and in 1855 was charged with a scientific mission to Europe. His poetry is exceedingly popular in Brazil.

DIAS, Bartholomeo, a Portuguese navigator, born in the latter part of the 15th century, lost in a storm at sea, May 29, 1500, while on his way from Brazil to India. In 1486 he sailed on an expedition to explore the W. coast of Africa, and without knowing it was carried around the southern point of the continent and landed at the mouth of Great Fish river, where he discovered that he was on the E. coast. The stormy cape he called *Cabo Tormentoso*, a name which the king of Portugal changed into Cape of Good Hope. Dias subsequently sailed on another African expedition under Vasco da Gama, and he commanded one of the vessels in the fleet with which Cabral discovered Brazil. It was on this expedition that he perished.

DIAS, Henrique, a Brazilian general, born at Pernambuco at the beginning, died in the latter part of the 17th century. He was a freed negro, who by his superior attainments rose in 1639 to

the supreme command of the colored soldiery of the Brazilian army. He took a conspicuous part in the protracted warfare which finally led to the overthrow of Dutch supremacy in Brazil.

DIASTASE (Gr. *διϊστημι*, to separate). When the grain of wheat, oats, or barley begins to germinate, there is formed at the base of the sprout a peculiar nitrogenous compound, very soluble in water, called diastase, the exact composition of which has never been determined. It is also found in the germ of the potato. It seems to be gluten in an altered form. By the action of this substance and of acetic acid, which also now first appears in the seed, the mucilaginous substance called dextrine, formed from the starch of the grain, is converted into starch sugar. This by fermentation passes into alcohol. It is therefore an essential element for the process of brewing. It may be obtained by digesting bruised barley malt with a little cold water, then expressing it through cloth. The liquor is then treated with sufficient alcohol to destroy its viscidity and cause the albumen to separate. This is removed by filtration. An additional quantity of alcohol then throws down the diastase in an impure state. It is redissolved in water and again precipitated with alcohol. When separated and dried, it is a white, tasteless, solid substance, without action upon gum or sugar, but capable at a temperature of 160° of converting starch suspended in water into dextrine, and this into grape sugar. One part of dextrine, it is found, is sufficient to cause 2,000 parts of starch to undergo this change.

DIATHERMANCY AND ATHERMANCY. The various dispositions of light entering the substance of different bodies are familiar. Some bodies, extinguishing the light, are termed opaque; others, through which it passes without sensible diminution, transparent, or diaphanous; but in most media both diaphaneity and extinction occur, in degree. Results entirely similar are now found to hold in the case of heat. All may observe that the sunbeams after passing through the air or through window glass are still very sensibly warm, while the glass and the air may remain at the same time in a great degree unwarmed. By a double convex lens of ice, the heat of the solar beam has been brought to a focus, and gunpowder and other combustibles fired, while the ice itself remained quite unaffected by the heat passing through it. A pane of glass held before a fire, however, stops the transmission of the heat striking it, and becomes warmed. From these facts, we conclude that from sources of heat there proceed outward on all sides rays of heat, just as from luminous bodies we have light rays; moreover, that there are media, as the air, which transmit heat rays freely, while others arrest (or, as it is often with doubtful propriety phrased, absorb) these rays; still a third class of bodies both transmitting and arresting portions of them. Bodies of the first of these classes are termed diathermanous; those of the second, athermanous; those of the third are imperfectly diathermanous. These subjects were first investigated in 1811–'12, by M. Prevost of Geneva, and M. de la Roche in France, but our knowledge of them is mainly due to M. Melloni, who began in 1832 a series of remarkable investigations, which won for him from M. de la Rive the title of "the Newton of heat." These researches, determining as they did the transmission of an invisible agent, heat, and often in degrees far too feeble to be detected by the nicest sensibility of the hand or by the ordinary means, would have been impossible but for the invention, by Nobili and Melloni, of a new thermoscopic apparatus, consisting of a thermo-electric pile connected with a highly sensitive galvanometer; the delicacy of the arrangement being such that if, in a room at ordinary temperatures, the human hand were presented in a line with the apparatus and at the distance of several feet, the heat radiating from the hand would cause the needle to be sensibly deflected. Some of the results discovered with the aid of this apparatus will be briefly stated. A plate or crystal of rock salt, even if an inch in thickness, was found, after diminishing the incident heat 7.7 per cent. by reflection, to transmit the entire remainder; this body, only, arrested within its substance no sensible portion of the heat rays. Hence, rock salt has been styled the true glass for heat; and its permeability by heat exceeds even that of glass by light. Smoked, or coated with soot, so as to be quite opaque, this body still allowed many of the heat rays to pass through it; and the same was true of smoked quartz and black glass. But citric acid, alum water, and limpid candy, although quite transparent, almost totally arrested the heat of the sun, of a flame or other source of intense heat, while they cut off entirely the rays from bodies raised to about red heat, and of all temperatures below. Bodies are not, therefore, diathermanous in proportion as they are transparent. But the amount of transmission of heat rays is found to depend on at least 4 particulars: 1, the nature of the source of heat; 2, the intensity of heat of the source; 3, the nature of the medium; and 4, its thickness. Solar heat has the greatest penetrating power; that of bodies in an incandescent state passes through the same medium in greater quantity than that of bodies at a dark heat; while of the heat of naked flame rock salt transmits 92.3 per cent., Iceland spar passes 39, white topaz 33, and alum 9 per cent.; and up to a certain thickness in every case, the amount transmitted diminishes with increase of thickness of the medium. Beyond a certain increase of the number or thickness of the plates, however, the diminution of heat ceases. The heat rays that can get through the first half inch or inch of glass, for example, will then go on undiminished through a much greater distance; so that it seems that certain heat rays are sifted out by each medium, as being incapable of moving through it with freedom; the others

then pass on. If, again, the heat beam which suffers no more loss by going through glass be now received in rock crystal, in the first part of this medium it suffers a remarkable diminution; other rays are sifted out, and a diminished beam passes. The same thing happens with light in colored media. The sunbeam in going through a certain depth of a red glass or solution has its bluish green rays sifted out and extinguished; the remainder, on being passed into a bluish green medium, is lost in like manner; a feeble beam only escapes, or none at all. Hence, the heat beam, like the beam of light, is regarded as a sheaf of heat rays of varying degrees of refrangibility; or we have a true heat spectrum. Dark and feeble sources of heat, it is found, emit rays analogous to blue and violet rays of light (Whewell), and highly luminous sources such as are analogous to yellow and red rays. The former, however, are proved to be the less refrangible heat rays; so that it is the more refrangible heat rays which are the more transmissible. This department of the subject has received the name of thermochrosy, or heat coloration. In this view, then, rock salt is a body quite colorless to heat; while alum, water, and some other transparent bodies, are nearly heat-black. The true heat color of water, however, is dark red, since the few rays it transmits are of the more refrangible class; and if this beam be received in a glass tinged green with copper, and the heat color of which may be considered blue, the remaining rays are lost; the heat beam is entirely arrested, though a greenish light still passes. This combination is then, apparently, a total black for heat. Where it is required to admit light without heat, therefore, this combination, or, as ordinarily more convenient, a solution or plate of alum, may be made the medium; where heat is to be admitted without light, smoked rock salt or black glass serves the purpose. In some operations in the arts, workmen exposed to an intense heat protect their faces to a good degree by wearing a glass mask.

DIATOMACEÆ, minute plants growing in moist situations, in collections of fresh water or in the sea, consisting of frustules of various forms, the walls of which contain a large quantity of silex, and are often beautifully diversified and marbled by striæ or by dots. Notwithstanding the general resemblance of these curious vegetations to the species of desmidieæ, they are clearly made distinct by the flinty fronds, singular striation, and absence of green coloring matter. Agardh asserts that many of these organisms have as much affinity with the mineral kingdom as with the vegetable, being in fact vegetable crystals, bounded by right lines and collected into a crystalliform body, and having no other difference from minerals than that the individuals have the power of again separating from each other. As in the case of the desmidieæ, there are solitary species, and others grouped so as to form lines and membranes. In some, the production of new plants from spores presents the same dissimilarity between the young and the adult forms. There are also numerous genera which can be accurately distinguished not only by the difference of form or outline, but by their own peculiar striations, markings, and dots. Both in the single and associated species there is a distinct pellucid peduncle or footstalk. This is sometimes considerably dilated above, or else forked, sometimes repeatedly. In this case, each frustule remains attached, the base dilating as may be required. This arrangement gives a fan-like appearance of great beauty. But in the thread-like species it is only the corners that remain attached; as no stem or footstalk is visible here, it has been conjectured that it exists only in those plants which have grown from spores or in the seedling forms. Certain channels or apertures are so arranged as to convey the water to the inner cellular membranes, and thus to afford nutriment. The same curious conjugation to be seen in other algæ has been detected in the diatomaceæ by Thwaites, and has been confirmed by Berkeley and Broome. It is computed that vast areas of solid earthy matter are due to the growth, presence, and decay of these minute organisms. Many of the most beautiful are found in the guano of commerce, doubtless swallowed in the food of birds, and still remaining in perfect preservation. In the United States, masses of several inches in thickness are found on the bottom of ponds, composed of myriads of these organisms, which on being exposed to desiccation become as white and friable as chalk. Even peat bogs and meadows abound with them. The polishing powders sold under the name of Tripoli are composed of these natural silicious fragments. The soundings on the shores of Victoria Barrier, in water whose average depth is 1,800 feet, were found by Dr. Hooker to be invariably charged with diatomaceous remains. These fossil species are often so identical with recent ones, that it were scarcely too extravagant to admit the assertion of Ehrenberg, that species are to be found in a living state in situations where they have been propagated from times far anterior to the existence of man. The United States are rich in the diatomaceæ, both fossil and living. We are indebted to the perseverance and scientific skill of the late Prof. J. W. Bailey, of West Point, N. Y., for a list and arrangement of species detected by him. In the tertiary infusorial stratum of Richmond, Va., Ehrenberg detected 20 genera and 46 species, of which all were also European excepting two. This group of American forms is of peculiar interest, because the strata at Richmond are decidedly of marine origin, and consequently give at once a general view of these marine microscopic forms along the North American coast. We shall briefly notice, in conclusion, some of the most remarkable of these vegetable organisms occurring in the United States and not uncommon in Europe. Of the perfectly free diatoms we have many species of *naviculaceæ* remarkable for beauty,

symmetry, delicacy, or else for their striations. The largest, most common, and most easily distinguished, is *N. viridis*, found in every ditch and pond, of an oblong outline. It can be detected in great abundance in the ashes of peat, and in the deposits of infusorial earths. Its length is about $\frac{1}{95}$ of a line. Several of a sigmoid outline are very remarkable for the delicacy of their striæ, of which may be mentioned *pleurosigma Baltica*, *P. hippocampus*, but more particularly *P. angulata*. The lines of striation upon *Nitzschia sigmoidea* are about $\frac{1}{100,000}$ of an inch apart. In *fragilaria* we have long threads of frustules adhering with considerable firmness at their commissures; but in *diatoma* they adhere only at a single point, so as to form curious chains of divided or separated joints. Prof. Bailey describes *bacillaria paradoxa* as a very interesting species, presenting by its curious motions and its paradoxical appearance an object well calculated to astonish all who behold it. At one moment the needle-shaped frustules lie side by side, forming a rectangular plate; suddenly one of the frustules slides forward a little way, the next slides a little also, and so on through the whole number, each, however, retaining a contact through part of its length with the adjoining ones. By this united motion the parallelogram is changed into a long line; then some of the frustules slide together again, so that the form is then much like a banner. Similar motions are constantly going on, and with such rapidity that the eye can scarcely follow them. The cause of this motion is wholly unknown, but it is most probably mechanical and not vital. Mr. Smith, in his work on the diatomaceæ, estimates this motion as being $\frac{1}{250}$ inch per second. In *meridion vernale* we have one of the most beautiful of the fresh-water diatoms. It consists of spiral or helicoidal chains, to perceive which the specimens must be tilted on edge. It occurs in immense quantities in mountain brooks, covering every submerged stone, or twig, or spear of grass, in the early days of spring. Among the groups with vittate or ribbon-like fronds, we may notice *striatella arcuata*, occurring in vast quantities on the filiform marine algæ, and covering them so much oftentimes as to make them glitter in the sunbeams as if invested with crystals. In still another natural group, where the striæ are no longer visible in the frustules or fronds, we find a multitude of microscopic objects, furnishing sources for fresh admiration whenever they are examined. In some of these the fronds, which are disciform, are marked with radiating lines, of which *coscinodiscus*, very common in a fossil state in the Richmond earth and elsewhere, is most beautiful. In *C. lineatus* the cellules of the frond form parallel lines in whatever direction they may be viewed, and *C. oculus iridis* gives curious colored rings. When perfect, the disk of *coscinodiscus* is covered with circular spots in rows corresponding with the radii. In consequence of this arrangement they also form beautiful spiral rows in other directions, so that the curves present no inconsiderable resemblance to patterns produced by engine-turning; at other times the spots are found to form 3 sets of lines, making angles of 60° and 120° with each other; and on others the spots are disposed without much apparent regularity, frequently having a star-like figure in the centre. The spots are so small on some of the disks as to be almost invisible even by the highest magnifying powers; on others they are quite large and hexagonal. In *podiscus Rogerii* (Bailey), the whole surface is so beautifully punctate, that no engraving could do it justice. The most complicated markings on the *coscinodiscus* scarcely rival the elaborate ornaments of this truly elegant organism. It has proved very common in Virginia and Maryland in a fossil condition. The beauty of *isthmia obliquata*, detected in the mud of Boston harbor, can only be appreciated by ocular examination. The diatomaceæ enter largely into the food of the mollusca. Dr. Hooker found *dictyocha aculeata* in the stomachs of salpæ taken off Victoria Land, and remains of diatomaceæ occurred in the same ascidiums examined between the latitudes of the N. tropic and 80° S. The medusæ are also in particular often filled with these forms.—See Bailey in "American Journal of Science and Arts," vols. xli., xlvi.; "Proceedings of Essex Institute," vol. i., pp. 33–48, and vol ii., pp. 70, 71; Smith's "British Diatomaceæ;" Kützing's *Species Algarum* (Leipsic, 1849); Berkeley's "Introduction to Cryptogamic Botany" (London, 1857).

DIAZ, Miguel, an Aragonese explorer, born in the latter part of the 15th century, died about 1514. He took part in the 2d expedition of Columbus, and having arrived in St. Domingo in 1495, he became involved in a duel which forced him to flee to the southern part of the island, where he married the female ruler of the tribe. From information given by her, and with the coöperation of Bartholomew Columbus, who was governor of the colony, he discovered the gold mines of St. Christopher, and afterward took a conspicuous part in the foundation of Nueva Isabella (afterward St. Domingo) in the vicinity of the gold districts. He faithfully adhered to the cause of Columbus until his death.

DIAZ DEL CASTILLO, Bernal, a Spanish adventurer and chronicler, born in Medina del Campo, Old Castile, about the close of the 15th century. He went to seek his fortune in the new world in 1514, and joined the expeditions which sailed from Cuba to Yucatan under Fernandez de Cordova in 1517, and under Grijalva in 1518. He afterward attached himself to the fortunes of Cortes, and followed that chief in all his most important battles and marches with distinguished valor and loyalty. In 1568 he was regidor of the city of Guatemala. When Gomara's "Chronicle of New Spain" appeared, Diaz began his *Historia verdadera de la conquista de la Nueva España*, the object of which was to correct the many

misstatements of his rival, and to claim for himself and his comrades a share of the glory which Gomara gave almost wholly to Cortes. The work was finished in 1558, and though destitute of literary merit, and disfigured by the author's vanity, it nowhere betrays a wilful perversion of truth, and is prized for its simplicity of style. It was first published at Madrid in 1632. An English translation by J. I. Lockhart appeared in 1844. A recent American writer has assailed the authenticity of the narrative, which he attempts to resolve into a collection of fables. (See Wilson's "New History of the Conquest of Mexico," Philadelphia, 1859.)

DIBDIN. I. Charles, an English song writer and composer, born in Southampton in 1745, died July 25, 1814. He was the 18th child of his parents, who intended him for the church. Following his own inclinations, however, he cultivated the study of music, and at the age of 16 went to London, where at first he supported himself by composing ballads for the music sellers and by tuning pianos. In 1763–'4 the opera of the "Shepherd's Artifice," written and composed by him, was produced at Covent Garden theatre, after which he appeared for several years in the joint capacity of actor and composer. Among his most popular works were the "Padlock," the "Deserter," the "Waterman," and the "Quaker," produced at Drury Lane, under the management of Garrick. Having quarrelled with the latter, he was for several years engaged in various theatrical speculations as manager or proprietor, and in 1789 instituted a species of musical entertainment, in which he was the sole author, composer, and performer. So successful did the enterprise prove, that in 1796 he erected a small theatre in Leicester fields, called Sans-Souci, in which he performed until 1805, when he retired from professional life in somewhat embarrassed circumstances, owing to his improvident habits. A pension of £200 was procured for him, of which in 1806 he was deprived by the whig ministry of Lord Grenville. The tory administration, which came into power the succeeding year, restored his name to the pension list, but his improvidence kept him in poverty until his death. His theatrical compositions, 47 of which are enumerated in the "Biographia Dramatica," amount to about 100. Upon his songs, however, of which he is said to have written upward of 1,000, his reputation mainly rests. Most of these were ephemeral productions, and many were below mediocrity; but his nautical songs and ballads are among the finest specimens of their kind in the language; and some of them, like "Poor Tom Bowling," written on the death of his brother Thomas, a sea captain, and "Poor Jack," are established favorites. They were set to simple and expressive melodies, and were exceedingly popular at the beginning of the present century, having, it is said, been influential in supplying the navy with volunteers. He published a history of the stage and some miscellaneous works of no great value. A new edition of his songs, with a memoir by T. Dibdin, illustrated by George Cruikshank, was published in London in 1850. II. Thomas, son of the preceding, born in London in 1771, died there, Sept. 16, 1841. He adopted the profession of his father, and for many years appeared before the public as actor, author, and composer. His songs and dramatic pieces are probably as numerous as those of his father, but are now comparatively forgotten. He died in poverty, while employed in compiling an edition of his father's sea songs, for which he received an allowance from the lords of the admiralty. III. Thomas Frognall, D.D., an English bibliographer, nephew of Charles Dibdin, born in Calcutta in 1775, died Nov. 18, 1847. He was educated at Oxford and studied for the law, but afterward took orders. In 1807 he became editor of a weekly journal called the "Director," and in 1809 published in the form of a dialogue his "Bibliomania," reprinted with great enlargements in 1811. In 1818 he travelled abroad, and in 1824 was appointed to the rectory of St. Mary's, Bryanstone square, which he held until his death. In 1814–'15 he published, under the title of "Bibliotheca Spenceriana," an account of the rare books in Earl Spencer's library, to which he afterward added a description of the earl's seat at Althorp, and an account of the Cassano library purchased by him. The work is often referred to, but is inaccurate. In his latter years Dr. Dibdin was involved in pecuniary embarrassment. His principal works, beside those above mentioned, are: "Typographical Antiquities of Great Britain" (4 vols., 1810–'20); "Bibliographical Decameron" (3 vols. 8vo., 1817); "Bibliographical, Antiquarian, and Picturesque Tour in France and Germany" (3 vols. 8vo., 1821); "Introduction to a Knowledge of rare and valuable Editions of the Greek and Roman Classics" (4th ed., 2 vols. 8vo., 1827); "Reminiscences of a Literary Life" (2 vols. 8vo., 1836); "Bibliographical, Antiquarian, and Picturesque Tour in the Northern Counties of England and Scotland" (3 vols. 8vo., 1839).

DICE (plural of die), small cubes of ivory, bone, serpentine stone, or close-grained wood, used in gaming. Each of their 6 faces is marked with a different number of points, from 1 to 6, in such a way that the numbers upon any 2 opposite sides together count 7. They are shaken and thrown from a box on to a table, and the game depends upon the number of points presented by the upper faces. This is one of the most ancient of games, and was said to have been invented by the Greeks to divert themselves during the siege of Troy. Plutarch makes it an early invention of the Egyptians, in whose mythological fables it is mentioned. Dice have been discovered in Thebes, made of bone or ivory, and similar to those in use at present. Herodotus ascribes the invention of this, as of all other games of chance, to the Lydians. It is alluded to as a favorite amusement by Æschylus and Sophocles. The chief distinction between the ancient and the modern game is, that in the

former 3 dice were employed, and in the latter ordinarily but 2. The Greeks gave to the various throws that were possible the names of their gods, heroes, princes, and hetæræ, the best throw being called Aphrodite. This game was adopted by the Romans, and the example of some of the emperors, especially of Nero, gave to it a dangerous popularity. Wealthy Romans, during the declining period of the empire, frequently staked their entire fortunes upon a single chance. It was introduced into France in the reign of Philip Augustus, and has continued from that time a favorite game.

DICE (Gr. Δικη), in ancient mythology, a goddess of justice, daughter of Jupiter and Themis, and sister of Eunomia (good rule) and Irene (peace). She appears as one of the Horæ, and as attendant of the father of the gods, and in the tragedians also as an avenging and rewarding divinity. Her business was not only to punish injustice, but to reward virtue.

DICENTRA (Borkh.), the generic name of some very showy herbaceous perennials, of which there are several species found wild in the United States. Of these latter, a very delicate and singularly flowered one is *D. cucullaria* (De Candolle), called Dutchman's breeches, the form of the corolla, with its spurs, reminding us of that article of apparel suspended in an inverted position. These blossoms are cream-colored tipped with white, and hang in a simple raceme upon a slender drooping scape, rising from the bosom of a set of tender, deeply cut, long-stalked leaves. Both the flowers and leaves soon fade away on the approach of summer, and leave exposed on the surface of the ground clusters of little grain-shaped tubers, arranged in the form of scaly bulbs. A second species, called squirrel corn (*D. Canadensis*, De C.), has scattered, round, flattened tubers, as large as grains of Indian corn, to the resemblance to which it owes its name. Its flowers are greenish white, tinged with red, and possess the fragrance of hyacinths. It is found in rich woodlands. *D. eximia* (De C.), found in W. New York, and among the Alleghanies of Virginia, is larger than the others, with reddish-purple flowers on a compound, clustered raceme, and with the lobes of the leaves broadly oblong. *D. chrysantha* (Hooker and Arnott), a native of California, has large, showy, golden-yellow flowers, leaves 2 and 3 pinnately divided, glaucous, with linear, acute segments, and a stem 2 or 3 feet high, leafy branching. But the most remarkable of all was introduced from Japan in 1846. From thick, brittle, fleshy roots there arise, early in the spring, numerous stout hollow stems about 3 feet high, bearing large, spreading, deeply divided, compoundly ternate leaves of a glaucous hue, not unlike some of the tree paeonias, from which issue strong flower stalks, branching into axillary and smaller racemes, loaded with large, rosy blossoms, each flower being about an inch long. In the early stage of the inflorescence the buds have a deeper tint, which is very beautiful. Several weeks elapse from the commencement of the expansion of the first blossoms until the period of blossoming is over; but sometimes a few smaller racemes will appear again toward the end of the summer. It does not seem to mature seeds readily, and as yet no new varieties are known to florists. This fine species has received the appropriate name of *D. spectabilis*. Side shoots or cuttings taken off early in spring, and planted out, will flower in August and September; but for early forcing it is better to put them into suitably sized pots, and suffer them to ripen away the foliage that has been produced in this condition, in preparation for another season, taking due care lest they strike their freely growing root fibres through the bottom of the pots. To prevent this, they may be placed upon a platform, on the stone or brick pavement, or even on the hard ground; in the latter case, it is better to move the pots at least once a week. On the approach of severe frost, the pots should be removed to the shed of the greenhouse, or placed under the stage, or protected in frames, or even put into the cellar, whence they are to be removed into a warmer atmosphere as they are needed for flowering. For early blossoming parlor plants we scarcely know of any other so easily prepared, or so sure of successful management, or which will so well reward any attention. In the garden the *dicentra spectabilis* thrives in any good soil, but that which is light, rich, and deep suits it best; in such a situation it will produce a dozen or more stems covered with flowers. A slight protection of leaves and litter is sufficient in winter. It should be allowed abundance of room.

DICK, Thomas, a Scottish scientific writer, born in Dundee in 1772, died at Broughty Ferry, July 29, 1857. He was educated for the ministry, and was ordained and settled as pastor of the Secession church in Stirling, but became so much devoted to scientific pursuits, that he relinquished his profession, and for 10 years was engaged as a teacher at Perth. While there he wrote the "Christian Philosopher," a work which brought him considerable reputation, and some pecuniary remuneration. From this time he devoted himself more exclusively to the writing of popular scientific works, which, though successful, were not a source of much pecuniary profit to their author, who was during part of his life in straitened circumstances. His works having had a large sale in the United States, a subscription was taken up for his benefit in this country some years before his death, and by this means, as well as by the contributions of some gentlemen of Dundee, and the aid of a small pension from the government, he was enabled to pass the latter years of his life in comfort. Among his works may also be mentioned, "Philosophy of Religion" (1825); "Improvement of Society by the Diffusion of Knowledge;" "Philosophy of a Future State" (1828); "Mental Illumination of Mankind" (1835); "Celestial Scenery" (1838); "Sidereal Heavens" (1840); "Telescope and Microscope" (1851).

DICKENS, Charles, an English novelist,

born at Portsmouth, Feb. 7, 1812. His father, Mr. John Dickens, who had held for many years an office in the navy pay department, retired on a pension in 1815 ; and being a man of some literary faculty, he became a reporter for the daily press in London. He intended his son for the profession of an attorney, and placed him in an attorney's office for that purpose. Here the youth acquired that knowledge of the machinery and technical phraseology of the law which he has turned to such good account in many of his works of fiction. But the drudgery of his work weighed heavily upon his spirit; a taste for literature, manifested mainly by an indiscriminate reading of novels and plays, began to develop itself; and his father's connections enabled him to exchange his uncongenial occupation for the more agreeable duties of a newspaper critic and reporter. He was attached to the "True Sun," and afterward to the "Morning Chronicle," which was at that time a daily paper of large circulation and influence. A series of sketches of London life, manners, and localities, published in the evening edition of the "Chronicle," under the signature of "Boz," attracted much attention, and showed the unknown writer to be possessed of a remarkable and original vein of observation and reflection, though by some it was regretted that such powers were exercised to so great an extent in the delineation of scenes of vice and misery, and the exposure of the weaknesses and infirmities of humanity. The sketches were afterward collected and published (1836) in 2 volumes. The ability displayed in these sketches was so great that Mr. Hall, of the firm of Chapman and Hall, proposed to the writer the scheme of preparing a work of fiction, to appear in monthly numbers, with illustrations by Mr. Seymour, a popular comic draughtsman. It was suggested that the adventures and mishaps of a club of originals would furnish a happy medium for the powers both of author and artist. Upon this hint the first number of the "Pickwick Papers" was written, and published with illustrations by Mr. Seymour. This clever artist died by his own hand before the appearance of the second number; and the task of illustration devolved upon Mr. H. K. Browne, who under the signature of "Phiz" continued with great spirit the style of pictorial embellishment which his predecessor had so happily begun. The work was completed and published collectively in 1837. But before it was finished it had attained a degree of popularity to which nothing in English literature since the publication of the Waverley novels could furnish a parallel. Everybody, both in England and America, was laughing over the ludicrous adventures of Mr. Pickwick and his associates, the trial scene of Bardell *vs.* Pickwick, and the quaint sayings, grotesque comparisons, and inimitable conversations of the elder and younger Weller. Between the appearance of the first and last numbers the author rose to be the most popular living writer in the English language. By some the "Pickwick Papers" is still esteemed Dickens's best work. We cannot subscribe to this judgment; but we admit that there are parts of it which he has never excelled, and that he has never drawn a character more original in conception and more happily sustained than that of Sam Weller. His next work, "Oliver Twist," appeared originally in monthly numbers in "Bentley's Miscellany," a magazine of which Dickens assumed for a time the editorship, and was published collectively in 1838. This novel fully sustained the high reputation acquired by the "Pickwick Papers." If the humor was not so rich, so abundant, so genial, there was a deeper tragic power, especially in painting the darker passions of the soul and the terrible retributions of guilt. Next appeared in serial numbers, published collectively in 1839, the "Life and Adventures of Nicholas Nickleby;" which, with some little hesitation, we should place at the head of all Dickens's novels, as being the most carefully constructed, and containing the widest range of character and the greatest variety of inventive power. From no other work of his could one who had never read any thing from his pen derive a more just estimate of all the wealth of his genius. "Master Humphrey's Clock," comprising the stories since separately known as the "Old Curiosity Shop" and "Barnaby Rudge," appeared in weekly numbers during 1840 and 1841. This was received, and deservedly so, with a degree of favor equal to that which had been accorded to his previous productions. Indeed, the character of little Nell awakened a depth and fervor of sympathetic admiration which no earlier creation had won. After the publication of this work, Dickens made a visit to America, arriving in Boston Jan. 22, 1842, and sailing for England on June 3 following. He was everywhere received with a degree of enthusiasm proportionate to his popularity as a writer and the excitable character of the American people. His views of American life and manners were published upon his return, at the close of 1842, under the title of "American Notes for General Circulation;" a work which added nothing to his reputation, though it was brightened here and there with gleams of his peculiar humor. In 1843 he wrote his "Christmas Carol," a short story inculcating the virtues of benevolence and generosity, which was received with great favor. Several similar productions have since from time to time appeared from his pen, under the general title of Christmas stories, of various degrees of merit, though no one can be pronounced quite equal to the first of the series. In 1844 he published in monthly numbers the "Life and Adventures of Martin Chuzzlewit;" and toward the close of the same year he went to Italy with his family, and resided there for some time. On Jan. 1, 1846, he assumed the editorship of the "Daily News," a morning newspaper started in London, on the liberal side in politics, to which several able writers were secured as contributors. In this journal were originally published his "Pictures

of Italy," which were gathered into a volume and issued in 1846; a work of a peculiar, almost unique character, containing as it does the impressions of a man of original genius who views Italy not as a scholar, an antiquary, or an artist, but as a humorist. He did not continue long in his new post of editor of a daily newspaper. His next publication, "Dealings with the Firm of Dombey and Son," came out in monthly numbers, during 1847 and 1848. In this novel the beautiful sketch of little Paul and the humorous delineation of Capt. Cuttle recalled the best efforts of his genius, and renewed the admiration awakened by his earlier works. Then followed the "History of David Copperfield," in monthly numbers, concluded in 1850. In this year he assumed the editorship of a weekly periodical, started by himself, called "Household Words," which has ever since continued to be published under his charge, and has a wide circulation both in England and America. Here appeared his "Child's History of England," republished separately in 1852; and his story of "Hard Times," republished in one volume, 1854. In 1853 was finished "Bleak House," which had been issued in monthly numbers; and in 1856 and 1857 "Little Dorrit" was given to the world, by parcels, in the same way. Beside the above works, Dickens is the author or editor of the "Memoirs of Joseph Grimaldi," published in 1836. Such a list proves him to be a man of vigorous industry and methodical habits of labor; and his example is valuable as showing that the highest genius is not incompatible with uniform diligence and a life of steady toil.—The great popularity which Dickens enjoys wherever the English language is spoken renders it a superfluous task for us to enter upon any extended or elaborate criticism of his works. He has opened a new and original vein of fictitious composition. His popularity is not a transient whim or fleeting fashion, but is fairly earned by great and obvious excellences. His place in English literature, throughout all time, will be as secure as that of Sterne, Fielding, or Scott. He is peculiarly and preëminently a man of genius. He has fashioned himself upon no existing models; no writer draws more exclusively from innate and self-contained sources; in no one do we see fewer indications of the influence of other men's minds. Very rarely in Dickens do we find a quotation from, or an allusion to, any other writer. His novels, as works of art, are open to obvious criticism. His plots are not skilfully constructed; many incidents are introduced which are improbable in themselves, and do not of necessity contribute any thing to the final catastrophe. His leading quality is his humor, which is original in its essence and boundless in its supply. His combinations, quaint, startling, and grotesque, are never forced, but are the spontaneous growth of a mind of inexhaustible fertility. In pathos, the reverse pole of humor, his merit is hardly less conspicuous. He has a peculiar comprehension of the sorrows and sufferings of childhood; and some of the most beautiful and effective of his pathetic passages have been drawn from this source. He is a very sharp observer, and an excellent artist in that style of verbal painting in which the effects are produced by the minute delineation of particulars. This power, it must be admitted, he uses rather too freely; and many of his descriptions, especially in his later works, would be improved by compression. The charm and success of his writings are in some degree to be ascribed to the fact that they are so strongly infused with the personal qualities of the writer. He is a man of genial nature and humane spirit, with a vehement hatred of injustice and oppression, a strong aversion to cant and hypocrisy, and generous and expanded sympathies. His powerful and popular pen has always been exerted on the side of social reform. Through these traits of character, as revealed in his writings, a sort of personal relation is established between him and his readers, which makes them very kind to his literary virtues, and a little blind to his literary faults. It has been objected to his novels that they set too high value upon good temper and geniality—the easy growth of a healthy organization and happy temperament—as compared with the sterner virtues which are the fruit of self-discipline and self-control; and that they make convivial pleasures too attractive, and fail to warn against convivial excesses. —Mr. Dickens has also acted with distinguished success in private theatricals, and has publicly read his own works to large and gratified audiences in almost every part of the United Kingdom. In 1858 he amicably separated from Mrs. Dickens, with whom he had lived some 20 years, and had several children. The cause was an uncongeniality of temper, implying no dishonor to either party.

DICKINSON, a N. W. co. of Iowa, bordering on Minnesota; area, 430 sq. m. The surface is diversified by a number of small lakes, the principal of which is Spirit lake. The largest river is the Okoboji, an affluent of the Little Sioux. This county is of very recent formation, and is not included in the census of 1856.

DICKINSON, Daniel Stevens, a U. S. senator from New York, born in Goshen, Conn., Sept. 11, 1800. The family removed in 1806 to the state of New York, and settled in the beautiful valley of the Chenango, where Daniel was inured to the hardy life of a plain farmer's son. He also worked for a while at a mechanical trade. During his boyhood he was able to acquire only the rudiments of learning under a system of common schools then in its infancy. Having a natural inclination to politics, he became an ardent member of the democratic party, and was rewarded for his zeal first by an election to the office of town constable, and then by an appointment as deputy sheriff of Chenango co. Thus brought in contact with the local courts, he took a fancy to the legal profession, studied law, was admitted to the bar about 1826–'7, soon became famous in the Chenango valley as a "rough and ready" practitioner before justices

of the peace, and worked his way steadily upward, till he obtained a good position and a fair business in the highest tribunals. He was chosen in 1836 a member of the state senate from the 6th district, for 4 years. He took a leading part in disposing of the many important questions that agitated the senate of New York in these 4 years—as the general banking law, the small bill law, the bank suspension law, and other financial measures arising out of the overthrow of the U. S. bank and the establishment of the independent treasury, the construction of the Erie railroad, the enlargement of the Erie canal, and other works of internal improvement; and he frequently delivered opinions upon grave legal questions brought before the senate, which, as the court for the correction of errors, was then the highest judicial body in the state. He won so much reputation during these 4 years in the legislature that at the close of his term the democratic party put him in nomination for lieutenant-governor. He was defeated, but 2 years subsequently (1842) he was triumphantly elected, thereupon becoming *ex officio* president of the senate, of the court of errors, and of the canal board, for 2 years. In 1844 he was a member of the convention that nominated Mr. Polk for the presidency, and was subsequently one of the electors at large for the state of New York. In December of that year he was appointed by Gov. Bouck, and afterward chosen by the legislature, to the U. S. senate, in the place of N. P. Tallmadge, where he continued till March 4, 1851. During 7 eventful sessions he took a prominent share in the discussion of the questions that convulsed that body, such as Texas annexation, Oregon joint occupation, the Mexican war and its consequent territorial acquisitions, the Wilmot proviso, and the compromise measures of 1850. On the power and duty of congress to prohibit slavery in the territories, he differed with his colleague, Gen. John A. Dix, as also with his subsequent colleague, Gov. Seward. In Dec. 1847, he introduced in the senate two resolutions respecting territorial government, which embodied the doctrine of "popular sovereignty," so called. This being anterior to the Nicholson letter of Gen. Cass, and long previous to the Kansas-Nebraska act of Judge Douglas, the credit of propounding that doctrine belongs to him rather than to either of them. While in the senate he was the ardent advocate of a branch mint in the city of New York, of the coinage of three-cent pieces, and of the free circulation of weekly newspapers through the mails within the counties where they are published. He was an effective debater, exerted a strong influence in the senate, and was honored by it with the chairmanship of the committee of finance. Mr. Dickinson's course on the slavery question placed him at the head of the conservative or "hunker" section of the democracy of New York, and rallied around him numerous friends in all parts of the Union, and especially in the southern states. He was brought forward as a democratic candidate for the presidency in 1852, and on one of the ballots in the national convention he received the influential vote of Virginia. But the hostility of the radicals in the New York delegation was implacable. They rallied upon Gov. Marcy as their candidate. The inability of Mr. Dickinson to secure the united vote of his state in the convention was sufficient (had there been no other obstacle) to prevent his nomination. On the election of Mr. Pierce to the presidency, Mr. Dickinson was strongly pressed for the secretaryship of state. His rival, Gov. Marcy, was selected, while he was appointed collector of the port of New York, but he refused the office. For 4 years Marcy wielded the federal patronage of the state against him. This was a heavy blow to his political influence. Still a large band of adherents continued faithful to him. The spirit with which he spurned the collectorship was generally applauded by his friends. He now withdrew to his rural retreat at Binghamton, and devoted himself to the practice of the law; and for the last few years he has indicated only through an occasional letter or speech that he still takes an interest in public affairs. Mr. Dickinson is a ready *nisi prius* lawyer, a strong, dashing speaker, quick to see and seize the point in controversy, apt at repartee, with a strong vein of humor, and well suited to the exigencies of American politics, whether encountered on the "stump," in the convention, or the senate chamber.

DICKINSON, John, an American statesman, born in Maryland, Nov. 13, 1732, died in Wilmington, Delaware, Feb. 14, 1808. He studied law in Philadelphia, and subsequently at the Temple, London, and upon returning to America practised with considerable success at the bar. Upon being elected to the Pennsylvania house of assembly in 1764, he evinced unusual capacities for a legislator, and was on all occasions a ready and energetic debater. At the same time he became known by his publications upon the attempts of the mother country to infringe the liberties of the colonies. In 1765 he was elected a deputy from Pennsylvania to the first colonial congress, the resolutions passed by which were drawn up by him. In 1768 he published his "Farmer's Letters to the Inhabitants of the British Colonies," which were republished in London with a preface by Dr. Franklin, and subsequently in French in Paris. He was a member of the first continental congress in 1774, and of the state papers put forth by that body some of the most important, including the "Declaration to the Armies," the 2 petitions to the king, and the "Address to the States," were the production of his pen. He, however, opposed the adoption of the "Declaration of Independence," believing that the movement was premature, and that compromise was still practicable, and was one of the few members of congress who did not sign that instrument. So unpopular did he become with his constituents for his course on this occasion, that for several years he was absent from the

public councils, although in the interim he signified his devotion to the American cause by serving as a private soldier in Delaware against the British forces. In 1779 he returned to congress as a member from Delaware, and wrote the "Address to the States" of May 26. He was subsequently president of the states of Delaware and Pennsylvania successively, and a member of the federal convention for framing a constitution. In 1788 appeared his "Fabius" letters, advocating the adoption of the new constitution. Another series over the same signature, on the relations of the United States with France, published in 1797, was his last work. His political writings were published in 2 vols. in 1801. He was a man of elegant learning and fine conversational powers.

DICKINSON, Jonathan, an American Presbyterian clergyman, born in Hatfield, Mass., April 22, 1688, died in Elizabethtown, N. J., Oct. 17, 1747. He was graduated at Yale college in 1706, and 2 or 3 years afterward was installed as pastor of the only Presbyterian congregation at that time existing in Elizabethtown, N. J., which relationship continued until his death. His parish comprised not only Elizabethtown, but the adjoining townships of Rahway, Westfield, Union, Springfield, and part of Chatham. After the separation of the New Jersey churches from the synod of Philadelphia in 1741, it was determined to establish a collegiate institution in the former colony, and a charter for the college of New Jersey was obtained from acting Governor Hamilton. The first classes were opened in Elizabethtown, and Dickinson was elected president. His services were acceptable in an eminent degree, but he did not live to confer the scholastic degrees upon his first class. His high reputation among his contemporaries, as a preacher and a controversialist, is well sustained by his published sermons and theological treatises.

DICKINSON COLLEGE. See Carlisle.

DICKSON, a N. N. W. co. of Tenn., bounded N. E. by Cumberland river, and drained by several of its affluents; area, about 650 sq. m.; pop. in 1850, 8,404, of whom 2,118 were slaves. It has a rolling surface and a tolerably fertile soil. Grain, hay, and live stock are the principal staples. In 1850 the productions were 388,731 bushels of Indian corn, 60,985 of oats, and 10,148 lbs. of wool. There were 20 churches, and 1,755 pupils attending public schools. The Cumberland river is navigable by steamboats along the border of the county. Capital, Charlotte.

DICKSON, Samuel Henry, an American physician, born in Charleston, S. C., in Sept. 1798. He was graduated at Yale college in 1814, and immediately after commenced the study of medicine in his native city; during the prevalence of the yellow fever there in 1817, he practised for a time. In 1818–'19 he attended the medical course of lectures of the university of Pennsylvania, and graduating in the latter year, at once entered upon the practice of his profession. He was instrumental in the establishment of a medical college in Charleston, and on its organization in 1824 he was called to the chair of institutes and practice of medicine. In 1832 he retired from this position, but in the following year, on the reorganization of the institution as the medical college of the state of South Carolina, he was reëlected. In 1847 he was called to succeed Dr. Revere in the professorship of the practice of medicine in the university of New York, which he filled during 3 successive years, till in 1850 he was induced, at the earnest solicitation of his former associates in the medical college of the state of South Carolina, to return to his professorship in that institution. In 1858 he was called to the chair of practice of medicine in the Jefferson medical college, Philadelphia, which he now fills. Dr. Dickson has contributed many papers on subjects connected with his profession to various medical journals throughout the United States, and is beside the author of the following books: "Manual of Pathology and Practice of Medicine," published in New York; "Essays on Pathology and Therapeutics" (2 vols. 8vo., New York, 1845); "Essays on Life, Sleep, Pain, &c." (12mo., Philadelphia, 1852); "Elements of Medicine (8vo., Philadelphia, 1835). In addition to these professional labors, he has delivered numerous speeches, lectures, and addresses on various subjects of general utility or interest. It is a fact worthy of note that he delivered the first temperance address ever heard south of Mason and Dixon's line.

DICQUEMARE, Jacques François, a French naturalist and astronomer, born in Havre, March 7, 1733, died March 29, 1789. He was a Catholic priest; became professor of experimental physics at Havre, member of the academy of Rouen and of the royal marine academy, and invented several useful instruments in connection with astronomy and navigation. He is better known, however, by his researches into the natural history of zoophytes, infusoria, and mollusks, and particularly by his interesting discoveries relative to sea anemones, on which he published an essay in French and English (4to., London, 1774). He designed an instrument called the cosmoplane, by means of which he solved problems in nautical astronomy. Beside more than 60 papers in the *Journal de physique*, he left an *Index géographique* (4to., 1769); *Idée générale de l'astronomie* (Paris, 1769); *Connaissance de l'astronomie* (8vo., 1771).

DICTATOR, the chief magistrate in the cities of the ancient Latin confederacy, in Alba, Tusculum, &c. The Romans adopted the word from their Latin neighbors, and applied it in the earliest period of the republic to exceptional magistrates appointed in times of danger, with nearly absolute power over life and property, from which there was no appeal to law or people. The dictator was usually nominated by the senate, and appointed by one of the consuls, for 6 months, during which time the consuls and other regular magistrates continued in their office, though subject to his dictates, and

deprived temporarily of their badges of dignity. The power of the dictator was mostly limited to one object, and particularly to foreign affairs. Being elected, he appointed his lieutenant or master of the horse (*magister equitum*), and surrounded himself with his 24 lictors (twice as many as attended the consuls), armed with fasces and axes, and well adapted to strike terror into the people. He was limited only in regard to the use of the public money, and responsible only after the expiration of his term; he was not allowed to leave Italy, or to appear on horseback within the precincts of the city. Officers bearing the same title were also sometimes appointed for certain civil or religious purposes, as for public solemnities, fixing the nail in the Capitoline temple of Jupiter (*clavi figendi causa*), &c. This office was quite harmless, but in later periods dictators were appointed *reipublicæ constituendæ causa* (to form a new constitution), such as Sylla and Cæsar, whose arbitrary power destroyed the republic. The first Roman dictator, Lartius, was appointed 9 years after the establishment of the republic (501 B. C.), to save the state from the threatening allies of Tarquin, the expelled king, and the more dangerous disturbances within the walls. The young republic, based on aristocratic foundations, was distracted by the greedy and exclusive spirit of the patricians, and the threats of the oppressed but unsubmissive and unruly plebeians. The public lands were in the grasp of the former, the latter were poor and degraded. The danger from the supporters of Tarquin was imminent; the senate commanded new levies, but the people refused to obey, declaring that they had nothing to defend, and that no foreign yoke could bring upon them greater hardships than those they endured. In their disobedience they were protected by the law recently passed through the efforts of Valerius Poplicola, which permitted every citizen, condemned to any severe punishment, to appeal to the people. To evade the force of this popular law, the senate agreed upon the extraordinary measure of electing a single magistrate with almost regal power. The people confirmed the decree, and the success and honesty of Lartius proved worthy of the new dignity. In the following year, another dictator, Aulus Posthumius, destroyed the last hopes of the banished king, in a battle fought near Lake Regillus. This battle, in which the 2 sons of the unhappy Tarquin fell, gave peace to the Romans. Not less remarkable were the services of the dictator L. Quintius Cincinnatus. When he was chosen dictator, the Æqui had surrounded and threatened to destroy a consular army. Cincinnatus routed them, and the vanquished army had to pass under the yoke. Rewarded with a triumph, and with the pardon of his banished son Cæso, he resigned his dignity within 17 days. C. M. Rutilus (356 B. C.) was the first plebeian appointed to the dictatorship, and M. G. Pera (216) was the last dictator, in the original sense of the word; for the same dignity, as bestowed on Sylla (82), and 3 times on Cæsar (47, 45, and 44), meant only unlimited, despotic sway. Mark Antony abolished it altogether.—In modern history, the word dictator, beside being a title of some regular chief magistrates in South America, designates a man appointed in times of danger, legally or illegally, to save a struggling nation, and vested with all its power, without any regard to law or constitution. This power has often been exercised in ancient and modern times, though not always under the same name. In the French revolution it was the dream of Marat, and Robespierre exercised it almost fully, by the influence of terrorism on the people and the convention, but fell before he could achieve his fanatical design of remodelling the world. Poland had an eminent dictator in Kosciuszko (1794). The revolution of 1830 proclaimed (Dec. 5) Gen. Chlopicki *naczelnik;* he was a good general, but proved a wavering and worse than useless dictator; he resigned, and fought as a brave soldier. In the unhappy rising of 1846, Tyssowski was for a few days dictator in Cracow. In the late Hungarian revolution, Kossuth exercised dictatorial influence before and after the declaration of independence, April 14, 1849, but within the strictest limits of constitutionality, voluntarily narrowed by himself. Görgey took the name and burden of dictatorship only for a few days, and for the use of it in the surrender of Világos, Aug. 13, 1849, received the curse of his army and nation. Manino in Venice, and Mazzini in Rome (1848–'9), acted like Kossuth, with the same zeal and activity, and the same result. The establishment of a dictatorship was unsuccessfully attempted in Paris, shortly after the revolution of February (May, 1848).

DICTIONARY (Lat. *dictio*, a word), in its ordinary acceptation, a book containing the words of a language, in alphabetical order, with a definition annexed to each. A complete dictionary would fulfil the same office with respect to language that a universal cyclopædia fulfils with respect to arts, sciences, and literature—giving an account of the origin and applications of the verbal symbols of ideas and facts, as the latter gives an account of the ideas and facts themselves. It would, therefore, state the etymology of words, and note their variations in meaning through the successive periods of a literature. A glossary is a dictionary of obsolete, provincial, or technical words; and the term lexicon, though hardly distinguished by usage from dictionary, is more frequently applied to vocabularies of the ancient and learned languages, with the definitions and explanations in some modern language. The Greeks and Romans appear not to have employed dictionaries in learning foreign languages, but uniformly to have availed themselves of conversation with foreigners. Nor have any early attempts at Greek lexicography been preserved. The oldest extant Greek dictionary is by Apollonius of Alexandria, a contemporary of Augustus

whose "Homeric Lexicon" (Λεξεις Ὁμηρικαι), though much interpolated, has been of value in modern times in interpreting the idioms of the Iliad and Odyssey. Erotianus, a Greek writer in the reign of Nero, made a glossary of all the learned words found in Hippocrates. Subsequent Greek dictionaries were the "Onomasticon" of Julius Pollux (about A. D. 177), containing explanations of the most important words relating to various prominent subjects, the arrangement being topical instead of alphabetical; the dictionary (Ἐκλογη) of Attic words and phrases, by Phrynichus, an Arabian or Bithynian, who lived under Marcus Aurelius; the dictionary of the words that occur in Plato, by Timæus the sophist, probably of the 3d century, which, though brief, contains the best explanations of terms that have come down from the ancient grammarians; a lost universal lexicon by Diogenianus of Heraclea, which is often quoted by Hesychius and Suidas, and which was abridged from an elaborate work by Pamphilus, also lost; the dictionary to the works of 10 Attic orators, by Valerius Harpocration, of unknown date, compiled from works now lost, and of the highest importance for its explanations of legal and political terms, and its accounts of persons and things mentioned in the Attic orations; the comprehensive Greek dictionary of Hesychius, an Alexandrian grammarian of the 4th century, which, though much disfigured and interpolated in its present form, is a vast accumulation of most heterogeneous materials, and has been a principal source of our knowledge of the Greek language and of many ancient customs; the lexicon (Λεξεων Συναγωγη) attributed to Photius, patriarch of Constantinople (died A. D. 891); and the Greek lexicon ascribed to Suidas, of unknown date, first quoted in the 12th century, which contains both common and proper names alphabetically arranged, and is valuable for the literary history of antiquity, and for its citations from ancient authors, as well as for its explanations of words.—The first Roman writer on lexicography was the learned M. Terentius Varro, whose work, *De Lingua Latina*, is however rather a voluminous treatise on the etymology and peculiar uses of words than a dictionary. Fragments only of it have been preserved. The elaborate work of Verrius Flaccus, in the earlier part of the 1st century, entitled *De Significatu Verborum*, is lost; but it was the basis of a valuable compilation by Pompeius Festus, in the 3d or 4th century, entitled *De Significatione Verborum*, which was abridged by Paulus Diaconus in the 8th century. Only one imperfect copy of the work of Festus is preserved. The words are classified alphabetically according to the initial letter of each, but the order of the subsequent letters is not observed. The information which it contains has been of great importance on many obscure points connected with antiquities, mythology, and grammar. Near the middle of the 11th century Papias of Lombardy compiled a Latin dictionary from the glossaries of the 6th and 7th centuries. An indication of progressive learning in Italy in the 13th century was the *Catholicon* of Giovanni Balbi, a Genoese monk, consisting of a Latin grammar followed by a copious dictionary. The work is in Latin, forms a volume of great bulk, was written in 1286, and is now celebrated as a rare typographical curiosity, its first edition having been printed by Gutenberg in 1460. The *Cornucopia* of Perotti, bishop of Siponto, printed in 1489, was a copious commentary on Martial, followed by an alphabetical index of words, and was of much service to subsequent compilers. The first edition of Calepino's Latin dictionary appeared at Reggio in 1502. At first only a Latin lexicon, additions of the corresponding Italian, Greek, German, &c., words were successively made, till it was extended (Basel, 1590–1627) to 11 languages; and it is still the most complete polyglot lexicon for the European languages. The French give the name *calepin* to any voluminous compilation. An epoch in Latin lexicography was made by the publication of Robert Stephens's *Thesaurus Linguæ Latinæ* (1532; 3d enlarged edition, 1543), which attempted to exhibit the proper use of words, not only in all the anomalies of idiom, but in every minute variation of sense. The most noted of subsequent Latin dictionaries is the *Lexicon totius Latinitatis* of Facciolati and Forcellini (Padua, 1771; 3d edition, 1831), in which every word is accompanied by its Italian and its Greek correlative, and which illustrates every meaning by examples from the classical authors. An English edition, edited by James Bailey, was published in London in 1828. Sir Thomas Elyot was the author of the first Latin-English dictionary (London, 1538), beyond the mere vocabularies of school boys. He was a distinguished scholar, and friend of Sir Thomas More, and his work reached the 3d edition in 1545. The largest similar work that had preceded it was the *Orbis Vocabulorum*, printed by Wynkin de Worde in 1500 (5th ed., 1518), which by successive improvements became the popular Latin-English dictionary of Ainsworth (1736). The most eminent Latin lexicographers since Forcellini are the German scholars Scheller, Freund, and Georges. The work of Forcellini was the basis of the Latin-English dictionary of F. P. Leverett (Boston, 1836); and that of Freund, of the Latin-English lexicon of E. A. Andrews (New York, 1856).—The first modern Greek-Latin dictionary was that of Johannes Crastonus of Piacenza (Milan, 1480; printed also by Aldus, 1497), which was for many years the only lexicographic aid for the student of Greek. Robert Constantine published at Basel, in 1562, a thesaurus of the Greek language, in which he had the assistance of Gesner, Turnebus, Camerarius, and other learned contemporaries. It was superseded by the *Thesaurus Linguæ Græcæ* of Henry Stephens (Paris, 1572), the result of 12 years' labor, which has hardly been surpassed in the comprehensive and copious interpretation of words.

Its arrangement is not in the alphabetical order of words but of roots, the derivatives and compounds being collected after each root. It was the basis of the works of Scapula and Schrevelius. The most thorough subsequent Greek lexicons are the German works of Schneider, Passow, Seiler, Rost, and Pape. The work of Passow was the basis of the Greek-English lexicon of Liddell and Scott (Oxford, 1845; New York, edited by Henry Drisler, 1848). The Greek language was long studied through the medium of the Latin, and no Greek-English lexicon was projected until the present century. The first of these that was announced was that of John Pickering (Boston, 1826; many subsequent editions), which was partially executed in 1814. It was preceded in publication only by the similar English work of John Jones (1823).—The first standard dictionaries of modern languages were produced under the patronage of learned academies; the oldest being the Italian *Vocabulario della Crusca*, first published in 1612, which was avowedly founded on Tuscan principles, made the 14th century the Augustan period of the language, and slighted the great writers of the 16th century. In Spain the lexicon of Lebrixa (1492) and the *Tesoro* of Covarrubias (1611) were the only dictionaries of note till the new academy produced its great work (6 vols., Madrid, 1726–'39), an abridgment of which was immediately prepared, the 5th revised edition of which was issued in 1817.—Though German lexicography begins with Hrabanus Maurus, a contemporary of Charlemagne, yet the first noteworthy German lexicon was *Die Teutsch Sprach* of Maaler (Zürich, 1561), and the first learned and critical work of the kind was Frisch's *Deutsch-Lat. Wörterbuch* (Berlin, 1741). All others have been superseded successively by the work of Adelung (Leipsic, 1774), and that of the brothers Grimm (Leipsic, 1852 *et seq.;* the 2d vol., reaching to the letter E, is nearly completed, April, 1859).—The dictionary of the French academy was published in 1694, and adopted the alphabetical order in its 2d edition in 1718. The 6th edition was issued in 1835. The first volume of a new, revised, and greatly enlarged edition appeared in 1859. It reaches only to the word *abusivement*, and the work if continued upon the same scale promises to occupy the academy for many generations. The dictionary of Trévoux, named from the town where it was first published in 1704, is at once a dictionary and a cyclopædia of curious knowledge. It was enlarged in successive editions, till in 1771 it reached its present magnitude, in 8 large folio vols., and it abounds in items of antiquarian and philological information.—The object of the first lexicographical labors in England was to facilitate the study of the Latin language, and bilingual dictionaries had become common while those designed for merely English readers were rare and meagre productions. One of the earliest of the latter was that of Dr. John Bullokar, entitled the "English Expositour" (London, 1616), explaining 5,080 of what were esteemed the "hardest words." It passed through many editions. Subsequent works were the "Glossographia, or Dictionary of Hard Words," by Thomas Blount (London, 1656); the "New World of English Words," by Edward Phillips, the nephew and pupil of Milton (1658); and the "Universal Etymological English Dictionary," by Nathan Bailey (London, 1726), in which the first attempt was made to give a complete collection of the words of the language, and which was long in the highest repute, and passed through at least 27 editions. An interleaved copy of a folio edition of Bailey's dictionary was the repository of the articles collected by Dr. Johnson in preparing his dictionary. The work of Johnson, after 8 years of arduous labor, appeared in 1755, and has exerted an influence superior to any other in fixing the external form of the language and settling the meaning of words. He first introduced into English lexicography the plan of illustrating the various significations of words by examples extracted from the best authors. It was much enlarged by Todd in the editions of 1814 and 1827, and has been the basis of many smaller works. The most important subsequent dictionaries are those of Richardson, Webster, and Worcester. Richardson's "New Dictionary of the English Language" (London, 2 vols. 4to., 1835–'37) is an elaborate work, especially valuable to the student of the history of the language. Its arrangement is in the alphabetical order of the primitives, beneath each of which its derivatives are grouped. Dr. Noah Webster was engaged 36 years on his "American Dictionary of the English Language," the first edition of which was issued in 1828, in New York (2 vols. 4to.), when the author was in his 70th year. A revised edition appeared in 1840 (2 vols. 8vo.), with the addition of several thousand words which in the intervening 12 years had passed from technological science into common language; and a revised appendix was added in 1843. A new edition, revised and enlarged by Prof. C. A. Goodrich, was published in Springfield, Mass., in 1848 (1 vol. 4to., 1400 pages). This work surpasses any that had preceded it in the comprehensiveness of its plan, the copiousness of its vocabulary, the fulness of its etymological department, and the accuracy and completeness of its definitions. Dr. J. E. Worcester's quarto dictionary, which has been preceded by two minor and preparatory works of high authority, is announced to be issued in 1859 in a volume of about 1800 pages.—The title of dictionary is sometimes given to alphabetically arranged cyclopædias, as dictionaries of biography, of the arts and sciences, of medicine, law, manufactures, commerce, and various other departments. (See CYCLOPÆDIA.)

DICTYS OF CRETE, a pseudonyme of the author of a history of the Trojan war, from which some ancient grammarians have imagined that Homer drew materials for the Iliad and Odyssey. The MS. of the work, written in Phœnician characters, is said to have been found in the au-

thor's tomb at Cnossus, in the reign of Nero, who caused it to be translated into Greek. A Latin version of the first 5 books has come down to us, but the work is commonly regarded as a forgery. Dictys is said to have followed Idomeneus, king of Crete, to the siege of Troy.

DIDEROT, Denis, a French writer and philosopher, born in Langres, Oct. 5, 1713, died in Paris, July 30, 1784. He was the son of a cutler, and was first educated for the church, but soon gave up theology to enter an attorney's office in the French metropolis. Law, however, did not occupy his time so much as literature and science, which he studied with enthusiastic diligence. He was then ordered by his father to select a profession, or return home; but neglecting to do either, he was deprived of his monthly allowance and found himself without means. Not discouraged in the least, he tried to make a living by teaching; and though often reduced to the greatest poverty, his devotion to letters and his careless and enthusiastic disposition carried him through all his troubles, not only during his early years, but during the whole of his life. Still penniless and unknown, he was married in 1743, under somewhat romantic circumstances, to Mlle. Champion, who was no better treated by fortune than himself; and then it was that he began to try his pen. He wrote an abridged translation of Stanyan's "History of Greece," and contributed to a "Dictionary of Medicine," accepting at the same time any literary employment that was offered him; thus he wrote for a preacher 6 sermons which brought him 50 crowns apiece, and this he frequently alluded to afterward as one of the best bargains he ever made. His domestic life was far from exemplary, and it was to satisfy the pecuniary demands of a woman, Madame de Puisieux, with whom he had contracted an intimacy, that he wrote his *Essai sur le mérite et la vertu*, in 1745; his *Pensées philosophiques*, in 1746, the boldness of which made a deep sensation, and was punished by a sentence of the parliament; his *Bijoux indiscrets*, a collection of obscene tales, of which he was himself ashamed; and his *Lettres sur les aveugles*, "for the use of those who see," in 1749, which procured him at once an acquaintance with Voltaire and 3 months' imprisonment at Vincennes, where he was often visited by Rousseau. On his liberation, having got rid of his mistress, he breathed a little more freely, and, in conjunction with D'Alembert, framed the plan of the work upon which his reputation is mostly founded, the *Encyclopédie*. Its professed aim was to present in a single work the truths of science, the principles of taste, and the processes of all the arts; but it was in fact a vehicle for the diffusion of new ideas among the reading public. This colossal undertaking, notwithstanding all sorts of troubles and difficulties, was carried through by the unflinching energy of Diderot, who was the soul of it. The prospectus of the work, the philosophical system of human knowledge, nearly all the articles upon ancient philosophy, and all those on the trades and industrial pursuits, are from his fertile pen, while after the withdrawal of D'Alembert he had the exclusive supervision of the whole. While preparing articles on the mechanic arts he often passed entire days in workshops, examining the machines in operation, and receiving explanations from the workmen, not unfrequently taking their place himself. The most eminent liberal thinkers of France ranged themselves under the banner of the *Encyclopédie*, 2 volumes of which appeared in 1751. Its hostility to Christianity had been anticipated, and a religious party was already formed to assail it. Complaints were made to the king, and by a decree of the royal council (Feb. 7, 1752) the 2 volumes were suppressed and the printing of others forbidden during 18 months. This suspension was revoked, 5 new volumes had appeared in 1757, and the work had 4,000 subscribers, when it was again assailed with a tempest of denunciations. Pompignan attacked the *philosophes* in the academy, Fréron in the *Année littéraire*, Palissot satirized them on the stage, Le Chapelain fulminated against them in a sermon before the king, and Le Hayer wrote a work of 21 volumes (1757) in refutation of them. The court, the parliament, the Sorbonne, and the threatre combined against the *Encyclopédie*, which was again suspended (March 8, 1759). D'Alembert, either wearied or frightened, deserted his partner, and Voltaire advised Diderot to flee from his country, and to complete his work enjoying the hospitality of Catharine of Russia. He, however, struggled firmly against all obstacles, replying to no raillery, and managing so well that he interested in his behalf the duke of Choiseul, Malesherbes, and even Madame de Pompadour. Permission was obtained to continue the publication at Paris, without subjecting it to censorship; but on the title-page Neufchâtel was to be printed instead of Paris, and the name of the editor was left blank. The 10 additional volumes were thus produced with no further difficulty, except that the publisher clandestinely mutilated many of the articles in the latter volumes after the final proofs had been received from the editor. While engaged on the *Encyclopédie*, Diderot, whose elastic mind could grasp every subject, wrote books of various kinds in his own name, and greatly contributed to those by his friends. Thus a large portion of Raynal's *Histoire philosophique du commerce des Européens dans les deux Indes* belongs to him, while the most eloquent pages of *De l'esprit*, by Helvetius, and of the *Système de la nature*, by D'Holbach, are attributed to his pen. The artistical part of Grimm's correspondence, known as *Les salons*, was written by him, and several letters on different subjects bear unmistakable marks of his hand. Under the impulse of his generous nature, Diderot was always ready to help the needy, his study being a sort of consulting office, where every one was welcome to good advice or more substantial aid. His personal influence over his time could scarcely be overrated. In 1757 and 1758 he produced 2 domestic dramas,

Le fils naturel and *Le père de famille*, which, though dull performances, paved the way to the change afterward accomplished in the dramatic style in France. His industry brought him in money, but his careless manner of spending it and his dissipated habits frequently involved him in pecuniary difficulties. In 1765 he was constrained to offer his library for sale. Catharine II. of Russia, being apprised of the fact, purchased it for 15,000 francs, but on condition that he would be the keeper of it at a salary of 1,000 francs a year; she moreover ordered 50 years' income to be paid at once. When the *Encyclopédie* was completed, Diderot paid a visit to his protectress, and spent several months at her court, where he was treated with great respect. On his return to Paris he published *Jacques le fataliste* and *La religieuse*, 2 novels which have been very extensively read, and in 1779 his *Essai sur les règnes de Claude et de Néron*, which is nothing else than an encomium of Seneca. His later years were passed in comparative quiet and comfort. He superintended the education of his daughter, and, to the astonishment of his friends, used to read the Bible with the young girl. He had been all his life considered a confirmed atheist, a reputation which his vehement attacks on the religion of the day served to sustain. During the last year of his life, he was frequently visited by the curate of St. Sulpice, with whom he was pleased to talk on religious subjects; and if he did not consent to any recantation of his philosophical opinions, he showed no particular enmity to Christianity. Toward the end of 1783 he had an apoplectic fit, and peacefully breathed his last among a circle of afflicted friends. He left an only daughter, Mme. de Vandeul, who wrote *Mémoires* of his life. His friend Naigeon published an edition of his works, in 15 vols. 8vo., 1798; but a more complete one, in 22 vols., appeard in 1822. To this must be added his *Mémoires et œuvres inédites*, 4 vols. 8vo., printed in 1830.

DIDIUS SALVIUS JULIANUS, Marcus, Roman emperor for a short time under the name of Marcus Didius Commodus Severus Julianus, born about A. D. 133, killed June 2, 193. Having filled successively the offices of quæstor, ædile, and prætor, he was appointed to the command of a legion in Germany, and afterward to the government of Belgica. Here he showed much energy in repressing an insurrection of the Chauci, a tribe living on the banks of the Elbe, and as a recompense for this service he was made consul. He also distinguished himself against the Catti, was governor of Dalmatia, and afterward of Lower Germany, and was then appointed to the charge of the commissariat in Italy. Having been accused of conspiring against the emperor Commodus, he was acquitted of the charge, while his accuser was condemned to death. After this he was governor of Bithynia in Asia Minor, was again consul, A. D. 179, and having filled the office of proconsul of Africa, returned to Rome, where he was made commander of the city guards, and where he lived in an extravagant and licentious manner. After the assassination of Pertinax, the prætorian guards who committed the deed offered the imperial throne to him who would pay the highest price; and after a brisk competition with Sulpicianus, the prefect of the city, Didius succeeded in obtaining it. The senate was obedient to the will of the unruly soldiery, and Didius was acknowledged emperor. But the people were not so cringing, and the new-made ruler, whenever he appeared in public, was received with cries of "Robber and parricide." Moreover, he was not recognized as emperor by Septimius Severus, who held command of 3 legions in Illyria, by Clodius Albinus, nor by Pescennius Niger, who held like commands in Britain and Syria respectively. Severus, having been proclaimed emperor by his troops, marched upon Rome, and was recognized by the senate. Deserted by almost all his former friends and adherents, Didius was murdered in his palace by a common soldier, having reigned a little more than 2 months, and Severus established himself in his place.

DIDO, or Elissa, a Phœnician princess and founder of Carthage, daughter of Mutgo, Belus, or Agenor, king of Tyre. According to Justin, she was the wife of her uncle Acerbas, priest of Hercules, who was murdered for his wealth by Pygmalion, the son and successor of Mutgo. Dido dissembled her sorrow, and with a number of disaffected Tyrian nobles succeeded in escaping from her native country, bearing with her the treasures of her murdered husband. The party first landed at the island of Cyprus, whence they carried off by force 80 maidens, and then pursuing their journey disembarked on the coast of Africa, purchased as much land as might be covered with the hide of a bull, and by cutting the hide into thin strips enclosed a large tract of country, on which the city of Carthage soon began to rise. The colony prospered so well as to excite the jealousy of a neighboring chief, Hiarbas, who demanded the hand of Dido in marriage, and threatened her with war in case of refusal. The queen asked 3 months for consideration, at the end of which time she caused a funeral pile to be prepared, and mounting upon it plunged a sword into her breast. Her story has been told with many variations and embellishments, and Virgil, with a disregard of chronology, which the charm of his narration may well excuse, represents her as killing herself for unrequited love of Æneas. The date of her founding of Carthage is thought to be 878 B. C., though Philistus places it 37 or even 50 years before the taking of Troy (1234 B. C.), and Servius as late as 40 years before the founding of Rome (793 B. C.).

DIDOT, the name of a French family of printers who have greatly contributed to improve the art of printing in their country. The firm, now existing under the name of Firmin Didot frères, was first established in 1713 by François Didot, who made himself known by

several important publications, and gained such popularity as to be appointed syndic of the booksellers' corporation. His two sons, François Ambroise (1730–1804) and Pierre François (1732–'95), increased the business, and paid especial attention to the printing department. While the latter established paper mills at Essonne, near Paris, the former materially improved the casting of types, the best specimens of which ever seen in France were from his type foundery; and his standard editions were admired for their correctness and beauty. The *Collection d'Artois* (64 vols. 18mo.), and the *Collection des classiques Français*, printed at once in 4to., 8vo., and 18mo., by order of Louis XVI., are still highly valued. Among the sons of Pierre, Henri, a type-founder, is known for the microscopical types with which he printed some little volumes which are esteemed as gems of their kind; and St. Léger engaged in the manufacture of paper. The sons of François Ambroise, Pierre (1760–1853) and Firmin (1764–1836), who succeeded their father at the beginning of the revolution, added to the good name of the firm by publishing magnificently executed folio editions of French and Latin writers, such as Racine, Horace, Virgil, &c., known as *Éditions du Louvre*. Firmin also aimed to furnish the general reader with cheap and correct editions. He invented, or more correctly, revived the stereotype process, which he brought at once to comparative perfection, and which has proved so invaluable to the public and the book trade. A man of classical attainments, he translated Virgil's "Bucolics" and Theocritus's "Idyls." He was elected in 1827 to the chamber of deputies. His sons, Ambroise Firmin, born in 1790, and Hyacinthe, born in 1794, have succeeded him in the management of the firm, enhancing its importance by well devised improvements and additions. Their publishing establishment has scarcely a rival in the world. Its head-quarters are in the rue Jacob in Paris, while the various manufactories, offices, and shops connected with it are established in the suburbs or the immediate vicinity of Paris. While the greatest attention is given to perfecting the present system of printing, every new process receives a fair trial. The assortment of type is perhaps the richest to be found in any private establishment, including not only every possible variety of modern, but also Greek and oriental characters. A complete catalogue of their publications would cover hundreds of pages, and include the titles of thousands of works. Among those especially worthy of notice, we mention: *Monuments de l'Égypte et de la Nubie*, by Champollion the younger; *Voyage de Jacquemont dans l'Inde; Expédition scientifique des Français en Morée; Thesaurus Linguæ Græcæ* of Henry Stephens, with annotations and additions by the best French and German scholars; a complete *Bibliothèque des auteurs Grecs*, a very cheap and correct edition of the Greek writers, with copious notes and Latin translations. Their editions of the French classics are as numerous as they are valuable; while their popular publications, such as *L'univers pittoresque*, *L'encyclopédie moderne*, *La nouvelle biographie générale*, &c., leave nothing to be desired in point of cheapness and correct execution. An idea may be formed of the importance of their present transactions by the fact, that on an average they print 140 reams of paper, or about 70,000 sheets, a day. The two heads of the firm are now aided by their sons Paul and Alfred, who have been by special training prepared to conduct the business of the firm and maintain its reputation.

DIDRON, Adolphe Napoléon, a French writer upon Christian art and archæology, born in Hautevillers, department of Marne, March 13, 1806. He travelled on foot through France, examining all the remarkable mediæval monuments, particularly those of Normandy. In 1838 he delivered in the *bibliothèque royale* a course of lectures on Christian iconography, after which he made a journey to Greece to compare the art of the Greek church with that of the West, and to obtain access to certain mediæval manuscripts. On his return to Paris he delivered another course of lectures, and in 1845 founded there an archæological publishing house, and a manufactory of painted glass. He was appointed in 1835 by the minister of public instruction secretary of the historical committee of arts and monuments, and is the author of the elaborate and interesting reports issued by that committee. He is also the editor of the "Archæological Annals," a periodical established by him in 1844, devoted particularly to the archæology of the middle ages, and in preparing which he is assisted by the principal archæologists, architects, designers, and engravers of Europe. His most important publication is his "Christian Iconography," of which an English translation was published in London (12mo. 1851).

DIDYMIUM (Gr. διδυμος, twin), a metal discovered in 1841 by Mosander in the mineral cerite, and named for its resemblance to the metal lanthanum, which occurs in the same mineral, and for the persistence with which its salts remain combined with those of this metal. The rose color of the salts of lanthanium is probably due to the presence of didymium. But neither of the two metals, nor the cerium with which they occur, possesses any special interest.

DIDYMUS, an Alexandrian grammarian and critic, born about 64 B. C. He was remarkable for his industry and the voluminousness of his writings, in consequence of which he received the nicknames of Χαλκεντερος, or brazen-bowelled, and Βιβλιολαθας, or forgetter of his books. The number of his works is stated by Athenæus at 3,500, and by Seneca at 4,000.

DIEBITSCH, Hans Karl Friedrich Anton, count, a general in the Russian service, born at Gross-Leippe, Silesia, May 13, 1785, died at Kleczewo, near Pultusk, in Poland, June 10, 1831. His father, who served under Frederic the Great and Frederic William II. of Prussia, and subsequently under Paul in Russia, sent him

in 1797 to the house of cadets in Berlin, but made him enter the ranks of the Russian imperial guard in 1801. He fought bravely in the battle of Austerlitz in 1805, in those of Eylau and Friedland in 1807, was made captain, devoted himself with zeal to the study of military science during the 5 years of peace which followed the treaty of Tilsit, served with great distinction under Wittgenstein during the invasion of the French in 1812, compelled, or rather persuaded, the Prussian general York to capitulate, was active as chief of Wittgenstein's staff in 1813, distinguished himself at Lützen, and was then attached as quartermaster-general to the corps of Barclay de Tolly in Silesia. Here he contributed to the conclusion of the secret treaty of Reichenbach between Russia, Prussia, Austria, and England, in June, 1813. He fought at Dresden, as well as at Leipsic, where he was made by Alexander lieutenant-general on the battle field. In the French campaign of 1814, when Schwartzenberg, frightened by the bold march of Napoleon, who threw himself between his army and the Rhine, advised the retreat of the allied armies, it was Diebitsch who decided for the march on Paris, which terminated the war. Arrived at Montmartre, the emperor Alexander embraced him, and decorated him with the order of Alexander Nevskoi. In 1815 he was married to a niece of Barclay de Tolly. After the return of Napoleon from Elba he was sent to the first corps, but was soon recalled to serve as adjutant of the emperor. Being made chief of the staff of the army, he accompanied Alexander on his journey through the south of Russia, and was present at his death at Taganrog in 1825. Having been sent with the news of this event to the grand duke Constantine at Warsaw, he returned to St. Petersburg, where he distinguished himself during the revolutionary outbreak of Dec. 25 by intrepidity, prudence, and humanity. The new emperor, Nicholas, rewarded his services with the title of baron, and afterward with that of count. In the war of 1828–'9 against Turkey, he acquired new renown by the taking of Varna, and by the crossing of the Balkan, which forced the Porte to make the peace of Adrianople, and procured him the name of Zabalkanskoi (Transbalkanian). Having spent some time at Berlin, he hastened to St. Petersburg at the news of the outbreak of the revolution in Warsaw, Nov. 29, 1830, and was appointed commander-in-chief of the army which was sent to put it down, as well as governor of the provinces adjoining Poland. Commencing the campaign in the midst of winter, he crossed the Polish frontier, Jan. 25, 1831; but the first engagements at Wisniew and Stoczek, Feb. 11, at Dobre on the 18th, at Grochow and Wawer on the 19th, in which the Poles fought heroically against overwhelming numbers, and still more the battles fought about the end of March in the vicinity of Praga, proved that fortune had left his banners. Without profiting by the favorable issue of the bloody battles of Nur, Lomza, and Ostrolenka (May 15–26), he removed his camp to Kleczewo, where he was suddenly overtaken by death, which was officially attributed to the cholera, but by general rumor to poison. Certain it is, that his deposition was determined upon, and that shortly before Count Orloff had arrived at the camp from St. Petersburg to examine into the condition of the army.

DIEFFENBACH, Johann Friedrich, a German surgeon, born in Königsberg, Prussia, in 1792, died in Berlin, Nov. 11, 1847. He was the son of a professor of theology, and at first devoted himself to that study, but broke off this peaceful pursuit to join in the war against Napoleon, serving as a volunteer in a company of Mecklenburg troops from 1813 to 1815. He afterward resumed his theological studies, which, however, he exchanged for the more congenial pursuit of medicine. Having taken his medical degree at Würzburg in 1822, he established himself at Berlin, where he had great success as a surgeon, and where, in 1830, he was appointed head surgeon of one of the hospitals, 2 years after professor in the university, and in 1840 director of clinical surgery in the same institution. Dieffenbach was especially distinguished for his remarkable dexterity in the use of the scalpel, for the success of his operations in the formation of artificial noses, cheeks, lips, &c., and for the cures which he effected in cases of squinting and stammering. He was, however, not eminent as a lecturer. Among his works may be mentioned the "Operative Surgery," his masterpiece, which has been translated into several different languages; "Surgical Experiences, especially with regard to the Restoration of Portions of the Human Body which have been destroyed;" "The Cure of Stammering by a new Surgical Operation;" and "On the Cutting of the Sinews and Muscles."

DIEL DU PARQUET, Jacques, a French colonial governor, died at St. Pierre, Martinique, Jan. 3, 1658. In 1638 he was appointed governor of Martinique by his uncle, D'Énambuc, the founder of the French colony on that island, and also of that on the island of St. Christopher. This appointment was afterward confirmed by the company which then had control of French affairs in the islands of America, and Du Parquet held the office until his death. He exerted himself vigorously to promote the welfare of the colony, which was in a miserable condition when he assumed the control of its affairs, and his efforts were attended with a gratifying success. He purchased from a Carib chief one of the small islands of the West Indies, and the seller, afterward repenting of his agreement, made war upon the colonists whom Du Parquet had established there. The contest was long and bloody, but at last the French compelled the savages to submit. Du Parquet introduced the cultivation of the sugar cane into Martinique. In 1650 he went to France, where he purchased for a large sum of money and an annual rent the ownership of the islands of Martinique Sainte Alousie, Grenada, and the Grenadines. He ad-

ministered the affairs of the colony with success for a period of nearly 20 years, and after his death, his wife, who was a woman of great energy, governed in his place for a time; but having been struck with paralysis, she embarked for Europe, and died on the passage in Aug. 1659.

DIEPPE, a seaport town of France, in the department of Seine-Inférieure, on the English channel, at the mouth of the Arques, 93 m. N. N. W. from Paris; lat. 49° 56′ N., long. 1° 5′ E.; pop. in 1856, 18,226. It extends a mile along the coast, has wide and regular streets, and its houses, mostly of the same style, are built of brick, 2 stories high, with balconies toward the street. The finest hotels and residences are near the harbor, on the Grand rue, or main street, which runs parallel with the sea the whole length of the town. The most remarkable public edifices are the churches of St. Remy and St. Jacques. The latter is a large structure in the Gothic style, was commenced in 1200, and not completed till after three centuries, and is built entirely of stone brought from England. The former is in the mixed Gothic-Saracenic style. Dieppe is well supplied with water by means of an aqueduct 3 m. in length, cut in the solid rock, which supplies 68 public and numerous private fountains. The port, enclosed by 2 jetties, is spacious and secure, with a basin of sufficient depth for vessels of 600 tons, but the entrance to it is difficult. Dieppe has 2 suburbs, La Barre and Le Pollet, and is the seat of a court of first resort and of a communal college. Its manufactures in ivory are the most famed in Europe. Its present distinction, however, is due mainly to its sea-baths, which, with its pure air and picturesque situation, have made it the chief watering place of France. The principal bathing establishment is an immense hotel, combining reception rooms, ball, concert, and billiard rooms, a theatre, and literary, social, and convivial saloons. In the early part of this century it first became, under the patronage of the gay duchess de Berry, the rendezvous during the summer of the noblest families in France. Dieppe was founded in the 10th century, in so favorable a position that in less than 4 centuries it had become the rival of Rouen. Dieppe mariners discovered Canada in the middle of the 16th century, and formed the first French settlements on the banks of the Senegal. It was bombarded by the English and Dutch in 1694.

DIEREVILLE, ——, a French traveller, born in Pont l'Evêque in the 17th century. He sailed for Acadia in 1699, remained there one year, and on his return published an account of the country, at first in verse, and afterward in prose (Paris, Rouen, and Amsterdam, 1708–'12). He brought back from America several new plants, one of which Tournefort named after him.

DIES IRÆ, the opening words of a celebrated Latin hymn upon the last judgment, which, on account of the sublimity of its ideas, and the fervent sentiment which pervades it, was early received into the liturgy of the Catholic church. The authorship of this terrible and beautiful poem has been variously ascribed to Gregory the Great in the 7th century, to St. Bernard of Clairvaux in the 12th, and to two Dominican monks and devotional poets, Umbertus and Frangipani, in the 13th. It is more probable that the true author was a Franciscan, Thomas de Celano, who was born in Abruzzo in 1221, was appointed guardian of the Minorite convents at Mentz, Worms, and Cologne, and in 1230 returned to Italy, where he died in 1255. When the Catholic church adopted this hymn into its liturgy, and added it to the service for the dead, cannot be precisely known, though it was certainly before the year 1385. At that time the text suffered some modifications; the beginning was omitted, and some verses added, composed by Felix Haemmerlin, who was hence for a long time regarded as the author of the entire hymn. It is as thus modified that it was included in the Roman missal, published in 1567 by order of the council of Trent, which is still used by the Roman Catholic church. The original text, *Dies iræ, dies illa*, is engraved upon a marble tablet in the church of St. Francis, at Mantua.

DIESKAU, Ludwig August, a German general who served in France, Germany, and America, born in 1701, died at Surenne, near Paris, in 1767. He was adjutant of Marshal Saxe, in whose interest he visited St. Petersburg in 1741. He accompanied him in the campaigns against the Netherlands, and became in 1748 brigadier-general of infantry, and commander of Brest. In 1755 he sailed as field marshal to Canada, at the head of French troops, to assist in the campaign against the English. With 600 Indians, as many Canadians, and 200 regular troops, he ascended Lake Champlain with the design of attacking Fort Edward. He defeated a detachment under Col. E. Williams, which had been sent against him, and pursued them to the British camp with the hope of entering it. The savages, however, halted just without the intrenchments, the Canadians became alarmed, and the regulars perished before the fire of New England marksmen. Dieskau, thrice wounded, refused to retire from the field, but, indignant at the conduct of his troops, seated himself on the stump of a tree, exposed to the rattle of the bullets. He was hit by a random shot after the flight of his army, and though wounded incurably, returned to Europe and lived several years, receiving a pension from France.

DIET (Fr. *diète*), a term applied to several political bodies of mediæval and modern Europe, corresponding to the parliament in Great Britain, the cortes in Spain and Portugal, the states-general, national assembly, and chambers in the history of France, and the congress in the United States. The derivation of the term from the Latin *dies*, day, as meaning a day fixed for the national deliberations on public affairs, is proved by the corresponding words in German (*Reichstag*), Dutch (*Rijksdag*), Swedish (*Riksdag*), and Danish (*Rigsdag*), all of which mean day of the empire; by the similar Swiss

term for the Helvetian diet (*Tagsatzung*), and by the verbs *tagen*, to be assembled, in German, and *ajourner*, to adjourn, in French, derived respectively from *Tag* and *jour*, day. It is used by English and French historians of the state assemblies of the German empire and confederation, Poland, Hungary, Sweden, Switzerland, and some other countries, to which the Germans apply the distinctive appellations of *Reichstag*, *Landtag*, *Landstände*, *Bundestag*, *Tagsatzung*, &c. The constitutional organization of the diets still existing in European states is described under the respective heads of the countries, while we add here a few remarks on those which, belonging to the past, are only historically important. The diet of the German empire, which must not be confounded with the popular assemblies of the Germanic nations in the Carlovingian times, or with the assembly (*Bundestag*) of the German confederation as established by the congress of Vienna, had its rise after the dissolution of the Frankish empire, and was slowly developed under the successive German houses, undergoing material changes, particularly in the reigns of the emperors Charles IV. in the 14th century, Frederic III. in the 15th, and Charles V. in the 16th, until it received its ultimate modifications by the treaty of Westphalia in 1648, and the session of Ratisbon in 1663. From this date down to the dissolution of the empire in 1806, Ratisbon became its permanent seat, while in previous times the emperor had the privilege of choosing the place of its sessions. The emperor, who formerly appeared in person, was now represented by a principal commissary, and all members of the empire by plenipotentiaries or agents. The diet consisted of 3 divisions, the so-called colleges of electors, princes, and imperial cities. The elector of Mentz, the archchancellor of the empire, presided in the electoral college, the archbishop of Saltzburg and the archduke of Austria alternately in the college of princes, and the city where the session was held in that of the cities. The electors and cities had individual votes, as well as the chief members of the college of princes, while the imperial counts and imperial prelates, who belonged to the latter, had only collective votes by benches, of which there were 4 of counts and 2 of prelates. Resolutions were passed by majority, except in religious matters and those concerning individual members of the empire alone. But the concurrence of all the 3 colleges and the ratification of the emperor were required to establish a decree of the empire (*Reichsschluss*). Concurrence in case of difference of opinion was obtained by reconsideration and conference. The emperor had the right of rejection, but not of modification. The collection of resolutions passed and sanctioned by a diet was termed imperial recess (*Reichsabschied*). The diet framed the laws of the empire, abolished and explained them, declared war and made peace, received and sent ambassadors, and concluded treaties. Imperial wars were proposed by the emperor, decided upon by majority, and carried on by the contingents of both the majority and the minority. —The Polish diet (*sejm*) dates principally from the reign of Ladislas the Short, who in 1331 assembled all the nobles of his kingdom. Its form was established by law under Casimir IV. In the last period of independent Poland it was convened regularly every 2 years, for a session of no more than 6 weeks, twice successively in Warsaw and the 3d time at Grodno, in Lithuania. It consisted of a senate and a chamber of deputies (*posel*, plur. *poslowie*). The latter were elected in previous municipal or district assemblies (*sejmik*, little diet). After the verification of their powers, the diet elected their president or marshal (*marszalek*). The most remarkable feature of the Polish diet is the so-called *liberum veto*, or the right of each member to prevent the enactment of a law or measure by individual opposition (*nie pozwalam*, I do not allow, or *veto*). This extreme of liberty, unknown in the history of any other nation, was remedied in part by confederations formed by the majority for the execution of its designs, and by timely application of violence, which silenced bribed or treacherous opponents; but it also led to fatal distractions, scenes of bloodshed, the permanence of factions, and finally, with other causes, to the fall of Poland. The diet of election was preceded by a diet of convocation, the archbishop of Gnesen, the primate of the state, having announced in a circular the death of the king, and the vacancy of the throne. Hereupon all nobles appeared personally, assembling on the plain of Wola, near Warsaw, the senate in a shed (*szopa*), the common nobles in the *kolo* (circle). A diet of coronation, and, if that of election had been stormy, another of pacification, followed.—The diet of Hungary (*diéta*, or *országgyülés*), formerly convened at various places, was finally regularly held at Presburg, except in the revolutionary periods, under Rákóczy and Kossuth. It consisted of 2 houses, the upper, or table of magnates, and the lower, or table of deputies. In the latter, previous to the law of 1848, only the representatives of the nobles in the counties had a decisive personal vote.

DIETERICI, Karl Friedrich Wilhelm, a German statistician and economist, born in Berlin, Aug. 23, 1790. He began his university studies in Königsberg, devoting particular attention to mathematics, and continued them in Berlin, where, in 1812, he became tutor in the family of Klewitz, minister of state. He studied history and law under Eichhorn, Rühs, Savigny, and Hoffmann. In 1813 he was appointed engineer in the army of Blücher, and in this position made the campaigns of 1813 and 1814. In 1815 he again served under Blücher, and in 1820 he was employed in the ministry of public instruction under Stein. In 1834 he was appointed professor of political science in the university of Berlin, and in 1844 succeeded Hoffmann in the direction of the statistical bureau. His writings are numerous, principally upon subjects of political econ-

omy. The most valuable of them are his "Statistical Survey of the most important Objects of Traffic and Consumption in the Prussian State and the German Commercial Union," and his "Prosperity of the People in the Prussian State."

DIETETICS. For his complete nutrition man must have presented to him in his food the albumen or fibrine of which his tissues are mainly composed, the iron and the salts contained in those tissues and in the blood and fatty matter, or some substance which can readily be converted into fat, which enters into the composition of his body, and which serves to maintain the animal heat. (See ALIMENT, ANIMAL HEAT, and ABSTINENCE.) But food must not only contain all the principles necessary to nutrition, it must likewise be digestible and assimilable; it must be capable of being disintegrated and dissolved in the alimentary canal, so that it may be absorbed, and finally converted into blood from which the waste of the tissues may be supplied. Digestibility and nutritive value bear no necessary relation to each other; an article of food may be highly nutritious and yet exceedingly indigestible, or it may be easily digestible and yet afford but little nutriment. While certain articles and classes of articles are in general more digestible, there is no rule of invariable application. There are innate differences in kind as well as in degree in the digestive as in the intellectual powers of mankind; and what will offend the stomach of one man, another no stronger or healthier will digest with ease. But aside from individual peculiarities, of which more will be said further on, there are other causes of difference more general in their character. 1. Habit has in this way great influence. What men have been used to, they digest with greater facility. An American or Englishman visiting the continent of Europe is frequently attacked with diarrhœa from an unaccustomed diet, which experience proves is equally wholesome with his own. During the revolutionary war numbers of the troops from the southern states while on duty at the North became ill, and their health was only restored by an allowance of fat bacon. The ill-fed Irishman on enlisting into the British army frequently is affected with what is termed a "meat fever;" his new diet is so much superior to what he was accustomed to, that his organs do not readily adapt themselves to the change. 2. The circumstances of the system have a great influence on the digestibility of food. A diet suited to Canada or Labrador would be oppressive and injurious in the West Indies or on the isthmus of Panama; the season, amount of clothing, exposure, exercise, have an influence on the digestive capacity as well as on the requirements of the system. 3. The digestibility of food is much influenced by our liking for it; within certain limits, what we are fond of agrees with us, and what we dislike is not apt to digest well. The *haut goût* which excites the appetite of the epicure provokes nausea in a less cultivated stomach. Still despite the various sources of diversity, some articles are for the majority of men of comparatively easy digestion, others are assimilated with greater difficulty.—Food is commonly classed in 2 great divisions, according as it is derived from the animal or vegetable kingdom. Animal food again may be subdivided into the flesh of mammals, birds, fishes, reptiles, crustaceans, and mollusks. The flesh of the mammals, and indeed of the birds and fishes used for food, differs very little in chemical composition. The fibrine, albumen, and gelatine of which chiefly they are made up, may be considered as chemically identical, from whatever animal they may be derived. The fats differ in the relative proportions, and sometimes in the character of the fatty acids which enter into their composition. The saline matters, varying in their proportions, are mainly of the same character, while the immense variety of flavors by which they are distinguished depend upon principles existing in exceedingly minute proportions, and for the most part soluble in water. The difference in meats arises from the varying proportions of fibrine, gelatine, and fat, and from variations in mechanical texture, and to these circumstances is due their difference in digestibility. Whatever renders the animal fibre harder, makes the meat less digestible; whatever renders it more delicate and tender, more easily separated and disintegrated, makes it more easily soluble in the juices of the stomach. Provided an animal has reached maturity, the tenderness of its meat is increased by youth, by its not having been worked, by its being in good condition, the muscular fibres interpenetrated and separated by minute proportions of fatty tissue. Keeping tends very much to improve the tenderness of meat. Few animals are fit to be eaten the day they are killed; but when kept, long before the slightest taint can be detected, a change takes place that renders the fibres more easily separated and disintegrated, more readily broken down and comminuted during mastication, and more quickly reduced and assimilated by the stomach. Of the different meats, venison that has been well kept is, in its season, perhaps the most tender and digestible. In Dr. Beaumont's experiments he found that in St. Martin a meal of broiled venison steak was completely digested and removed from the stomach in 1½ hours, a shorter time than was required by any other meat. Wether mutton of a proper age, that has hung for a sufficient length of time, is scarcely inferior in digestibility to venison. Beef ranks next to mutton. The flesh of the lamb and of the calf are less digestible than mutton or beef, and of the two, veal is less readily digested than lamb. Of all the meats in ordinary use, pork is most refractory to the gastric juices; and, contrary to what holds with regard to beef and mutton, the sucking pig is more digestible than pork. The fat of meats generally, and all varieties of fatty matters, are difficult of assimilation; they are particularly offensive to weak stomachs, sometimes appearing to form an oily pellicle,

which, floating on the partially chymified mass, becomes rancid and occasions distressing heart-burn and nausea, or causes eructations of acrid matter which leave a peculiarly disagreeable taste upon the palate. The mode of dressing meat has a great influence upon its digestibility; that which agrees best with the majority of stomachs is broiling. The fire should be brisk, so that the albumen on the surface of the meat may be rapidly coagulated; this preserves the juices of the meat, and it is rendered at once more savory and more tender. The same rule applies to boiling and roasting. When the meat is to be cooked, if boiled, it should be at once plunged into boiling water; the coagulation of the albumen on the surface thus produced, protects the interior from loss; while if soup is to be made, the meat should be put into cold water and the temperature slowly and gradually raised, thus extracting its nutritious fluids to the greatest possible extent. Of all methods of cooking, frying is the most objectionable; not only is the meat rendered harder than when boiled, and thus more indigestible, but it becomes imbued with boiling fat, and is thus rendered still more refractory to the gastric juice. Rich stews are objectionable on the same account; the fat set free by the heat penetrates and is absorbed by the meat, and renders it liable to offend delicate stomachs. By the action of salt on muscular flesh, the juices of the meat are abstracted; in this manner not only is its nutritive value impaired (see ALIMENT), but it is rendered harder and drier and consequently more indigestible; the longer the flesh is exposed to the action of salt, the harder and drier it becomes. Perhaps all fats form an exception to the fact that meat is rendered more indigestible by salting; they have little water to lose, and their texture cannot consequently become consolidated; fat pork is even rendered more digestible by salting. St. Martin, according to Dr. Beaumont's observations, digested recently salted pork when raw or broiled in from 3 hours to 3 hours and 15 minutes; the same article fried occupied him 4 hours 15 minutes for its reduction; while fresh pork, fat and lean, roasted, required 5 hours 15 minutes. On the other hand, boiled fresh beef with a little salt was digested in 2 hours 45 minutes, while old salted beef required 4 hours 15 minutes when dressed in the same manner. All empyreumatic substances impair digestion by interfering with the action of the animal matter, the pepsin, which is the principal solvent agent of the gastric juice. In this manner smoking impairs the digestibility of meat; few things are more difficult of management by a feeble stomach than old and well-smoked beef. Of poultry, the turkey is most digestible. St. Martin found fowls, roasted or boiled, of slower digestion than beef; ducks and geese, as might be supposed from the amount of fat they contain, are assimilated with difficulty. Fish furnishes an abundant and digestible variety of food. The dry, white sorts, cod, haddock, bass, &c., are the most digestible; while the richer kinds, salmon, shad, mackerel, eels, &c., are less apt to agree with the stomach. St. Martin digested boiled or fried salmon trout in 1½ hours, boiled dried cod in 2 hours, fried catfish in 3 hours 20 minutes, and boiled pickled salmon in 4 hours. Milk, the only food during the earlier months of infancy, contains from 12 to 13 per cent. of solid matter, about ⅓ of what is contained in flesh; it is poorer in plastic and richer in respiratory food; its ash furnishes but 0.47 per cent. of iron, while those of flesh and wheat flour yield 1 per cent. It is not digested so quickly as would be supposed, and in this respect boiled has the advantage of unboiled milk; the one took St. Martin 2 hours, the other 2¼, to convert into chyme. Milk disagrees with a great many persons; this is often connected with the readiness with which it undergoes change when exposed to the atmosphere, and this change commences long before it can be recognized by the taste. Milk just drawn from the cow agrees perfectly with many persons who are unable to take it when a few hours old. When cows are kept in an impure and confined atmosphere, it has been conclusively shown that their milk produces disturbance of the digestive organs and diarrhœa in infants who are fed upon it, and there is good reason to believe that constitutional diseases, scrofula and phthisis, may be thus developed. The caseine of milk, coagulated, generally mixed with more or less butter, and pressed so as to free it from the whey, constitutes cheese. Its richness varies with the quantity of butter it contains; some varieties, Stilton for instance, are made from milk to which an additional quantity of cream has been added. Salt is used to preserve it, and some kinds, as Dutch cheese, are very highly salted. When cheese is kept for a length of time, it undergoes a number of changes, partly dependent on the liberation of the volatile fatty acids existing in the butter, partly in the richer varieties, on the commencement of putrefactive fermentation. The firm, close texture of cheese renders it always hard of digestion, and the rich and strong-smelling varieties are particularly to be avoided by delicate stomachs. Fresh sweet butter is, perhaps, the most wholesome and digestible of fatty matters; by heating or rancidity its digestibility is greatly impaired.—Of farinaceous articles, light well-made wheaten bread, from 12 to 24 hours old, is the most generally digestible; warm bread is indigestible, because it forms a tough mass not readily penetrated by the saliva and rebellious to the gastric juices. Unleavened bread, maccaroni, and vermicelli are wholesome, and agree well with the stomach; on the other hand, flour combined with fatty matter, whether in the form of pastry, cake, or pudding, is more or less indigestible, according to its texture and richness. Next to wheat flour, rye affords the best and most wholesome bread. In various countries oatmeal, barley, and maize are used as substitutes for wheat; they form kinds of bread wholesome enough for those habituated

to its use, but apt to disagree with strangers. In tropical countries rice to a great extent takes the place of the other cereals, and perhaps a larger population mainly subsist on it than on any other single article of food. It affords very little of plastic or blood-making material, and hence when taken alone is consumed in enormous quantity; as an adjunct it forms an unstimulating and digestible article of food. The leguminous seeds, peas and beans, afford a nutriment rich in plastic matter, but hard of digestion and predisposing to flatulence. Sugar is used chiefly as an addition to other articles of diet; when refined, it contains no plastic matter, and is simply a heat-producing aliment, in general abundantly wholesome; the popular prejudice that it produces caries of the teeth has no good foundation. Closely allied to sugar are the various forms of fecula, arrow root, tapioca, sago, potato starch, &c. They consist of minute granules enclosed in a membranous envelope; this membrane must be burst by heat or panification before the starch is digestible. It is then an unstimulating food, entirely respiratory in its character, it containing little or no plastic matter. Contrary to general opinion, young infants digest starch with difficulty, and when fed largely upon it, pass it unchanged by stool. Vegetables constitute an important part of our diet. With few exceptions their nutritive value is low; they consist largely of water holding organic salts in solution, of starch granules, of small quantities of albuminous matter, and of cellulose and epidermis. The cellulose, though possessing a chemical constitution identical with that of starch, when at all firm, resists the action of the gastric juice, and passes unchanged through the intestinal canal. They are valuable on account of their large quantities of organic salts, of the bulk which they give to the food, and of their stimulating effect upon the peristaltic action of the intestines. These latter qualities make them disagree where the digestive organs are feeble and irritable. They are digestible in proportion to their tenderness and the readiness with which they can be broken up into a pulp. The potato has about the same nutritive value as rice; it requires to be thoroughly masticated, and is therefore an unsuitable article for young children. St. Martin found potatoes roasted and baked disposed of more readily than when boiled, the one taking 2 hours and 30 minutes to be converted into chyme, the other an hour longer. The same rule applies to fruits as to vegetables; they are digestible just in proportion to the readiness with which they can be completely reduced to a pulp. Ripe strawberries, peaches, oranges, grapes, rarely disagree, while cherries, apples, pears, &c., are more indigestible; roasting improves the digestibility of apples by rupturing the cells in which their juices are imprisoned.

DIETRICH, Christian Wilhelm Ernst, also called Dietrioy, a German painter and engraver, born in Weimar, Oct. 30, 1712, died in Dresden April 24, 1774, excelled principally in the imitation of the great masters, especially Rembrandt, though he copied with great success the styles of other eminent painters.

DIFFERENTIAL CALCULUS, the science called by the English fluxions, is the most valuable of mathematical modes, from the great variety of subjects to which it is applicable, and from the strength of its solvent power. Its discovery is justly assigned to the latter part of the 17th century, although there were doubtless some hints of it among earlier writers. Archimedes had demonstrated the area of a parabola to be $\frac{2}{3}$ of its circumscribing rectangle, and also the truth of his celebrated propositions concerning the sphere and the cylinder. Kepler, seizing the spirit of his method, introduced the words infinite and infinitesimal into geometry. Cavalieri, Roberval, and Fermat enlarged the application of his mode. In the meanwhile Vieta, Cardan, Harriot, and others had improved algebra, and Descartes had applied it to geometry by his invaluable system of variable coördinates. Thus the way was prepared for Leibnitz and Newton, who, independently of each other, invented the differential calculus, although differing in the form in which they conceived of and expressed the same truths. Newton's discovery or invention was made in 1665, and that of Leibnitz several years later. The notation of the latter was so convenient, and his mode of attacking the subject had such a practical superiority for the learner, that Newton's method of fluxions has now gone completely out of use; although in a metaphysical point of view Newton's mode is not open to the objections which may be brought against that of Leibnitz. The discovery of this method originated in the investigation of curved lines, but is extended to the consideration of every species of magnitude. Newton conceived of a curved line as generated by the motion of a point; and the spirit of his method consists in determining the velocity with which the point, at each instant, is moving in a given direction different from that of the line; that is, *e. g.*, if the point be moving in a general southwesterly direction, in determining the velocity with which it souths compared with that with which it wests. The spirit of Leibnitz's method consists in supposing the curve to be composed of infinitely short straight lines, and in determining the direction of each of these little straight arcs. What Newton called the inverse method of fluxions is now called the integral calculus. It consists in finding from the ratio of infinitesimal changes the magnitude and law of connection of the changing quantities. The whole calculus is too difficult and abstruse for any popular exposition. The reader may find general views upon the subject in Davies's "Logic of Mathematics," and Comte's "Philosophy of Mathematics," translated by Prof. Gillespie, or in French in Carnot's *Reflexions*. For gaining a practical acquaintance with the science there are numerous accessible treatises, among which

Church's and Courtenay's are well adapted to ordinary students, but Peirce's conducts much more rapidly into the highest walks. Of English treatises, Price's holds the highest rank. The French have been prolific writers upon the subject; among them Duhamel perhaps holds as high a rank as any.

DIFFRACTION OF LIGHT, the deviation from a straight line which a ray of light undergoes in passing near the edge of an opaque body. In whatever way light be transmitted, the luminous influence may be regarded as propagated in the manner of a succession of hollow spheres, or shells, that spring forth from the surface of the luminary and enlarge with almost inconceivable rapidity on all sides of it through space. In the undulatory theory of light, each of these shells is considered to be a wave, or we may say, a wave-front, advancing in the form of a spherical surface, as ripples about an agitated point upon a pond of water spread outward in concentric circles. But in a homogeneous medium, the line of effect, or that in which the agitation is propagated outward from the centre of disturbance, is a straight line; and thus we say that light advances in rays, and that in a uniform medium these are straight. To this law, however, one important general exception has been found. Grimaldi, an Italian Jesuit, about the middle of the 17th century, observed that when through 2 small orifices near together 2 pencils of the sun's light—diverging, of course, in consequence of the size of the sun's disk—were admitted to fall on a screen at several feet distance in an otherwise dark room, the overlapping parts of the 2 disks of light thus obtained were brightly illuminated, while on either side of this central bright band there were alternating curved bands of less and greater illumination and showing the prismatic colors. The effect is still better seen when the pencils are made more divergent by being each brought by a convex lens to form a minute focus, beyond which the rays must again separate. These bands are known as "Grimaldi's fringes." If 2 narrow slits in the shutter are employed, the result is a bright band running longitudinally through the middle of the space occupied by their light on the screen, with alternating fringes on the 2 sides. So, if in the centre of a single divergent beam a small opaque body be held, the actual complete shadow of it on the screen is less in size than the geometrical shadow; but it is surrounded by alternating light and dark bands to a distance which again causes the shadow in part to encroach on the surrounding space. The same result, in a degree, really happens with a single small pencil; and in fact, all shadows are in this way to some extent encroached on by surrounding light, and all edges of light by shadows. Here, then, is a set of cases in which the rays of light deviate from straight lines; and it may be stated that, generally, rays of light grazing upon the edges of orifices or of bodies are bent more or less out of a straight line, being turned apparently both within and without their previous direction. This action is the diffraction of light. Newton attempted to explain this action of the edges of bodies in accordance with the theory of emission, by supposing that the edges exerted some influence of attraction or repulsion, according to the condition in which the imagined luminous particles met them. But it was found that when the light employed in these experiments was monochromatic, as red only, or yellow, the bands produced in any case were simply light and dark, *i. e.*, of the given color and absolutely black. And Dr. Young discovered in 1803 that in order to obliterate all the special fringes obtained in the case of 2 orifices, it was only necessary to cover up one of them; portions of the spot obtained from the other which were before crossed by dark bands immediately became light. It thus became evident that light can be added to light in such a way as to produce darkness. In water waves, a crest and a trough of equal depth, that is, 2 equal waves in opposite phases, coming together, neutralize each other, and give still water over the space thus occupied; and 2 sound waves may also so blend as to produce silence. Fresnel in 1815–'16 read before the French academy of sciences the results of his investigations of this set of phenomena, which he, as well as Dr. Young before him, judged could not be explained by the theory of emission, but which he found perfectly in harmony with consequences flowing from Huyghens's undulatory theory of light. By varying the material and shape of the orifices, he found no effect whatever upon the appearance of the fringes, except that when razor-edges were employed the rays were bent about these more than about rounded edges, an effect which has been termed inflection of the light. But he wholly disproved the Newtonian view, by throwing a diverging pencil from the focus of a lens on 2 mirrors slightly inclined to each other, so as to make the reflected rays cross in their course: here were no edges; yet, when the 2 sets of rays were received on a screen, the light and dark bands were perfectly formed; and by covering one mirror, the bands disappeared, the other giving light only. This phenomenon then, in all its forms, is due to interference, and, according to the undulatory theory, that of 2 waves or sets of waves, so managed, in the case of the mirrors, that they shall intersect each other at points along their course; where, in homogeneous light, crests conspire with crests, or troughs with troughs, producing increased brightness, but where crest and trough combine at the same point, producing rest of the vibrating medium, that is, darkness. In compound or solar light, however, the effect of the interference is to separate the ray into its elementary colors. In the case of rays grazing the edges of orifices or bodies, the points at which the rays thus touch become points of origin of new agitations or waves, which spread out from these points as centres beyond the body, and by so doing intersect each other and produce light

and dark bands. Mathematically, it is easily proved that those surfaces of intersection along which crests will conspire to give increased light, and also those along which crests and troughs will combine to give darkness, must form along the middle line one continued plane surface, and on both sides of this, receding hyperboloid surfaces; and experiment, as in placing the screen successively at various distances, marks out exactly these curves about a middle bright band, as those actually formed. The bands thus formed are broadest in the least refrangible (red) rays, and narrowest and most crowded in the most refrangible (violet) light. The accurate measurement with a micrometer of the distances of the successive bands from the central line, together with the other known distances in the case, becomes a ready means of determining the wave lengths of the different colored rays composing white light; and it is by observing that when either of 2 pencils forming them is retarded, the fringes must shift to that side, and finding that when one of the pencils passes through a thin film of mica, or a tube of water, the fringes do actually move to the side occupied by this pencil, that it has lately been proved, in different ways severally by Arago, Foucault, and Fizeau, that light moves less rapidly in the denser of 2 media, a fact which has given to the emission theory of light its final overthrow. As consequences of this view of the production of the fringes, it follows also that the centre of the shadow of a small opaque body held in a diverging pencil of light should be a minute bright spot, while the centre of the light of the pencil without the opaque body should be a small dark spot; both these results are found to hold true. By varying the shape of the orifice, the form of the dark or light space will be changed. Shadows, as formed, do not correspond accurately with the geometrical shadows of the bodies projecting them; but in the case of large bodies or apertures the fringes are less sensible. In order to witness the effect of diffraction by a simple experiment, make a smooth pin-hole in a piece of card paper, or a clean cut down into one of its sides: by looking through this, in a room otherwise dark, at a minute crevice admitting light by the shutter or door, or at the flame of a candle, either of these will present numerous light and dark bands, the candle flame being multiplied apparently into a number of flames, lessening out on either side, and showing the prismatic colors. Bring a bright star or the light of a lamp at a distance just over the edge of an intervening body, as the hand or a bar in the shutter, and a good eye will detect that in a position just preceding that of the disappearance of the light it is decomposed, showing the prismatic colors, the red and green very distinctly. Many cases of diffraction occur in nature. Among these are the colored fringes seen by looking in certain directions at or along the course of fine fibres of any kind, as the spider's web, fine wires, and the fibres upon black fabrics, when illuminated by the sun; the fringes sometimes bordering the shadows of such bodies; the colors seen by looking through a fine dew or mist between 2 plates of glass, or upon a mirror on which lycopodium has been dusted, held in the sun; the changeable colors of the plumage of birds, and those of mother-of-pearl and other grooved or striated surfaces, the origin of the colors in the latter cases being proved by taking casts of such surfaces in black wax, which immediately become iridescent, like the natural objects, and by grooving metallic surfaces with 5,000 to 10,000 lines to the inch, as in Barton's iris buttons, in which the same result appears.

DIFFUSION OF GASES, a term applied by Priestley (who first observed the phenomenon, and published an account of it in the 4th volume of the "Transactions of the American Philosophical Society") to the property possessed by gaseous bodies of intermingling with each other, whatever may be their differences of specific gravity, or whatever their repugnance to enter into chemical combinations. Priestley found the new force so strong that the gases would in time penetrate animal membrane that separated them and that was regarded air-tight, and be found constituting similar mixtures on each side of it. To this principle he correctly attributed the uniformity of the composition of the atmosphere. Dalton, who afterward investigated the subject, explained the phenomenon on the assumption that the particles of one gas are highly repulsive to each other, but do not repel those of another gas. So, when a jar of hydrogen is inverted over another filled with carbonic acid, the light gas finds its way between the particles of the heavy gas, and this works upward into the other, till they are at last equally diffused. Thus he supposed one gas to act as a vacuum to another, with which it does not enter into chemical combination; with this difference, however, that the particles of one present a mechanical impediment to the diffusion, so that a longer time is required for it to take place. This explanation accounts also for the uniform diffusion of vapors through gases and through each other. Prof. Graham of Glasgow made some further interesting investigations as to the relative rate of diffusion of different gases. Gas contained in a glass jar slightly cracked was found to escape into the air, and the air at the same time to pass through and mingle with the gas, and the relative quantities that passed each way were found to depend upon the comparative densities of the two elastic fluids; the lightest gases passing through most rapidly, the rate of diffusion being inversely as the square root of the density of the gas. This law would seem to confirm the hypothesis that gases act as vacuums to one another; for it is found that the velocities of gases flowing into a vacuum maintain the same ratio, being inversely as the square root of the densities of the gases.

DIGAMMA (double gamma), so called from its form (F) resembling 2 gammas (Γ), the 6th

letter in the ancient alphabet of the Greeks, corresponding to the Hebrew ו and the Latin *f*, and probably equivalent in sound to the English *w*. It continued latest in the Æolic dialect, but early became obsolete in the Attic alphabet, and subsequently in the Greek language; though its original existence is indicated by the fact that the 5th letter (ε) is the numerical symbol for 5, but the next letter (ζ) for 7. It does not appear in the Homeric poems, though they were composed when it was in use; but its force remained in the metre after its form had disappeared, and its latent existence at the beginning of many words and syllables apparently commencing with a vowel made preceding short syllables, if ending with a consonant, long by position, or, if ending with a vowel, prevented a hiatus. In passing into the Latin language it was written *v*, thus: *ἑσπερος* (ΓΕΣΠΕΡΟΣ), *vesperus*; *ὠον* (ΩϜΟΝ), *ovum*.

DIGBY, a S. W. co. of Nova Scotia, bordering on the Atlantic; pop. in 1851, 12,252. It has a highly diversified surface, and comprises within its limits several small lakes, which give rise to numerous rivers. The underlying rock is sandstone of various colors. Copper and silver mines have been worked with some profit. In the N. W. part is a deep and narrow bay of the Atlantic called St. Mary's bay, enclosed on the N. by Brial's island and a narrow headland known as Digby neck. Capital, Digby.

DIGBY, Sir Kenelm, an English philosopher and chemist, born in Gothurst, Buckinghamshire, in 1603, died in London in 1665. He was the son of Sir Everard Digby, who was executed for complicity in the gunpowder plot, when the subject of this sketch was about 3 years old. He was educated in the Protestant faith, and showed early tokens of remarkable talent. In 1621, having finished his education at Oxford, he visited the continent, where he travelled for about 2 years. On his return he was made gentleman of the bedchamber by Charles I., and received other marks of the royal favor. In 1628 he sailed with a squadron fitted out at his own expense, to fight the Algerines and the Venetians, with whom the English had quarrelled, and gained much credit by his courage and success on this expedition. In 1636, while in France, he became a convert to the Roman Catholic religion; and, having afterward returned to England, and taken part with the king in the civil war, was imprisoned by order of parliament. During his confinement he employed himself with literary labors, was released in 1643 in consequence of the intercession of the queen of France, and retired to that country, where he was received with great honor, and enjoyed the friendship of Descartes and other eminent Frenchmen. From this time till 1661 he lived mostly on the continent, and especially in France, employing himself with literary and scientific labors. Having returned to England, he enjoyed the favor of Charles II., and continued his philosophical studies until his death. His principal works are: "A Conference with a Lady about the choice of a Religion;" "Observations on Religio Medici;" a "Treatise on the Nature of Bodies;" a "Treatise on the Soul, proving its Immortality;" a "Treatise of adhering to God;" "Of the Cure of Wounds by the Powder of Sympathy;" "Private Memoirs of Sir Kenelm Digby, &c., written by Himself," first published in 1827.

DIGESTION, a function peculiar to the animal kingdom, by which organic alimentary substances, introduced into the stomach and intestines, are converted into the nutritive fluid, chyle, and mixed indirectly with the blood, the excrementitious and useless matters being rejected and cast out of the body. The organs by which this function is performed in the higher animals are the mouth, pharynx, œsophagus, stomach, and intestines, with their accessory salivary glands, pancreas, liver, and mucous follicles. The first act to which food is subjected is the mechanical division by the teeth; so important is this in order that it may be influenced by the salivary secretion, that it may be said as an axiom that "food well chewed is half digested." As a people the Americans are singularly guilty of life-long and constant infraction of this rule, paying, however, the penalty of dyspepsia with its numerous train of evils and premature decay. The action of the gastric juice and of the pancreatic and biliary secretions has been described in the articles Chyme and Chyle. While some of the nutritive matters are dissolved in and absorbed directly from the stomach, others require further preparation, and are taken up by the vessels and absorbents of the intestines; by the time that the residue arrives in the cæcum, almost all the alimentary matter has been extracted, and the insoluble portions with the excess of biliary and mucous secretions are voided at the anal termination of the canal. The digestive process, upon the proper performance of which the health of all the organs must depend, can hardly be separated from absorption, which takes up the nutritive materials, and assimilation, which converts them into a fluid resembling blood, poured into the circulation near the heart. Though inorganic substances are necessary for the support of the body, the organic alone are generally considered as food and as subjects for the digestive process. Organic substances used as food may be conveniently arranged under 4 heads: 1, the saccharine group, embracing substances composed of oxygen, hydrogen, and carbon, resembling sugar in composition, and readily convertible into it; such are starch, gum, woody fibre, and the cellulose of plants; 2, the oleaginous group, with a great preponderance of hydrogen and carbon, small proportion of oxygen, and absence of nitrogen, including vegetable oils and animal fats; 3, the albuminous group, containing a large proportion of nitrogen, comprising animal and vegetable substances allied in chemical composition to albumen and animal tissues; 4, the gelatinous group, including animal substances closely allied

to gelatine; also containing nitrogen. The saccharine substances cannot form part of any animal tissue, but, when converted in the body into those of the oleaginous group, may like these last go to nourish the adipose and nervous tissues; but by far their greater portion is used in the maintenance of the animal heat. Starch seems to be converted into sugar, and sugar into lactic acid, in which form it is oxidized and burned off; oleaginous matters appear to undergo oxidation without any preliminary change; these non-nitrogenized compounds cannot minister to the plastic growth of the body, as is proved by the death from inanition of animals fed exclusively upon them. The articles of the albuminous group serve not only for nutrition, but for the maintenance of heat, if required, by their decomposition; the proportion of their 4 elements is the same in all, and they are all capable of reduction to a like condition by the digestive process, so that, as far as nutrition goes, the fibrine of animals, the albumen of eggs, the caseine of milk, and the gluten of wheat are equally acceptable to the organism. No one of these, however, is alone sufficient to support life; it is very remarkable, as Dr. Prout has observed, that the only single article of food naturally provided for the continued growth of animals, milk, contains albuminous caseine in its curd, a good deal of oily matter, and considerable sugar.—Supposing mastication to have been thoroughly performed, the food is first acted upon by the salivary fluid, which is secreted by the parotid, sublingual, and submaxillary glands, and the follicles of the mucous membrane of the mouth. Saliva is but little heavier than water, contains minute corpuscles and epithelial scales, and in health has an alkaline reaction greatest during and after meals. It consists of about 995 parts of water in 1,000, and 5 parts of solid matters; of the latter the most remarkable is ptyalin, to which the peculiar properties of the fluid are due; it closely resembles, but is not identical with, albumen and caseine; it acts the part of a ferment, and, according to Mialhe, 1 part is sufficient to convert 2,000 parts of starch into sugar; it also contains a compound of sulpho-cyanogen, not known to occur in any other animal product, and interesting in a medico-legal point of view; its salts are nearly those of the blood, and its alkaline reaction seems to be due to the basic phosphate of soda; the "tartar" of the teeth and salivary concretions consist principally of earthy phosphates and animal matter. The limpid secretion of the parotid and sublingual glands saturates the food during proper mastication, while the viscid submaxillary fluid facilitates swallowing when the tongue carries the mass back toward the pharynx. The amount of saliva secreted daily by man will average, according to Bidder and Schmidt, 3½ lbs., though it varies with the character and frequency of the meals. Beside its mechanical action, it is believed that the saliva, by its peculiar ferment, acts chemically upon the farinaceous elements of the food, leading to the conversion of the starch into sugar, the action continuing even in presence of the acid of the stomach; there is no satisfactory evidence that saliva exerts any other than a physical action upon nitrogenized substances. When the food reaches the stomach the digestion is continued by the gastric juice, secreted by the numerous follicles of the mucous membrane, lined with lobular cells and glandular epithelium. Bernard's experiments show that the secretion is mainly poured out toward the pyloric extremity of the organ. The nature of the digestive process has been the subject of much speculation in past times. It was at first supposed that the aliments underwent a coction similar to that which they would experience in a vessel with hot water; to this succeeded the theory of acid fermentation, then of putrefaction, of trituration, and of maceration, till the present belief in the solvent action of the gastric juice was established. The gastric juice is transparent, nearly colorless, and with very slight viscidity. Its most characteristic feature is acidity, which is even perceptible to the taste. Many eminent chemists maintain that the real agent in the solvent process is free lactic acid, while others are in favor of free hydrochloric acid; the latter seems to be true of man, and the former of dogs and pigs, which have been the most frequent subjects of experiment. The peculiar organic ferment of the gastric juice is pepsin, which disposes albuminous matters to undergo solution by the contained hydrochloric acid, which they would otherwise only partially do unless exposed to a high temperature. The secretion of the empty stomach is neutral or alkaline, but it becomes acid on the introduction and during the digestion of food, resuming its neutral character when this process is finished. From the experiments of Dr. Dalton, it appears that an ounce of gastric juice will dissolve a little over 30 grains of fresh lean meat; at this rate the full digestion of a pound of raw meat would require 2 gallons of gastric juice; and this apparently enormous quantity will not be considered incredible, if it be recollected that this fluid after it has done its work of solution is at once reabsorbed into the circulation, so that even this quantity might be secreted during the 3 or 4 hours of the digestive process, at an expense to the blood of not more than 2 or 3 oz. of fluid at any one time; the fluid does not accumulate in the stomach, but its watery portions are in continual process of secretion and reabsorption as long as any food remains undigested, within reasonable limits as to quantity ingested. Many of the most important phenomena of gastric digestion have been rendered familiar and visible by the experiments of Dr. Beaumont and others within a few years on Alexis St. Martin, through an opening in whose stomach the effect of food, stimulants, and sedatives could be seen. The color of the membrane was pale pink, its appearance velvet-like, and its surface lined with a transparent viscid mucus; the irritation of food caused the innumer-

able follicles to become prominent, and to pour out the acid gastric juice; small quantities of very cold water, or ice, after the primary sedative effect, caused turgidity of the membrane and copious secretion, while ice in large amount and long continued retarded the process. The amount of gastric juice secreted depends on the requirements of the system, and not on the quantity of food taken into the stomach; this is most important to be remembered, since, after the fluid secreted has dissolved all it can, any excess of food must remain undigested, pass into the intestines in a crude state, and become a source of pain and irritation until it is expelled. When the system is diseased, there is no craving for food, which if taken would not cause the secretion of the gastric juice, but would remain undigested for 24 or 48 hours, adding its irritation to the general diseased state. Excess in eating or drinking causes erythematic inflammation of the stomach, and acridity of the secreted fluid, which if long continued disorders digestion, and betrays itself to the physician by aphthous ulcerations and other morbid appearances of the mouth and tongue. The secretion of gastric juice is influenced by, though not dependent on, nervous agency; it is well known that mental emotion will put a stop to the digestive process, and section of the pneumogastric nerves arrests for a time the elaboration of the gastric fluid. There can be no doubt that the process of gastric digestion is essentially one of chemical solution, the solvent fluid being prepared by the follicles of the stomach, and its action assisted by the peristaltic muscular movements of the organ; the experiments on St. Martin fully prove these facts, both in natural and artificial digestion. Rapidity of digestion depends so much on the quantity and quality of the food, the state of health, the condition of the mind, and the habits of exercise, that it is difficult to determine the relative digestibility of different articles of diet; it appears from Dr. Beaumont's researches that, other things being equal, the flesh of wild animals is more easily digested than that of the allied domesticated races; in this respect venison stands first, then turkey, then beef, mutton, and veal, in the order mentioned. A certain bulk of food is necessary for healthy digestion, as has long been practically known by uncivilized nations; soups and fluid aliment are not more readily chymified than solid substances, and cannot alone support the system in vigor. Moderate exercise before a meal facilitates digestion. A temperature of 98° to 100° F. is requisite for the perfect action of the gastric juice; hence the ingestion of cold and iced substances, so generally used at the present day, must be very prejudicial to digestion. The most recent experiments go to show that the action of the gastric juice is confined to nitrogenized substances, and that it exerts no influence on starchy, saccharine, or oily matters. Starch is acted upon by the salivary fluid, sugar is dissolved, and oily substances are reduced to a state of fine division without the agency of the gastric juice. Its action on albuminous matters is to reduce them to a complete solution, alter their chemical properties, and convert them into albuminose (a kind of imperfect albumen), in which form they are readily assimilated. In this condition they form definite combinations with the solvent liquid, which have been called peptones; these are not mere solutions of the respective substances in acidulated fluids, for a converting power is exerted by the pepsin, the solvent power being due to the acid of the gastric juice. The process of digestion is far from being completed in the stomach; the action of the biliary and pancreatic fluids has been noticed under Bile and Chyle, and the end of the digestive act under Cæcum. As mental depression will retard digestion, so a mind at ease and a joyful spirit will promote it. The merry laugh not only indicates a mental condition favorable for the natural secretion of the gastric juice, but by shaking the sides favors the movements of the stomach so essential to perfect digestion; so that the saying, "Laugh and grow fat," is founded upon physiological principles. Until digestion has been partially completed, both orifices of the stomach are closed, a beautiful provision of nature keeping the pylorus shut, and allowing no undigested matter to pass out, unless its faithful fibres are overpowered by too much or improper food. Indeed, the digestive system affords some of the most admirable proofs of creative design, whether we consider the mechanism of chewing and swallowing, the reduction of different alimentary articles to a homogeneous chyme, the absorption of some parts by the stomach itself and of others by the special lacteals, the changes effected by the secretions of the liver and pancreas, or the removal of superfluous and injurious substances. When it is remembered what control, for good or for evil, the human race has over these processes, it must be admitted that a knowledge of the physiology of digestion is of the first importance to health and happiness.—For further details on the subject of digestion, the reader is referred to Todd and Bowman's "Physiological Anatomy," Carpenter's works on physiology, and the work of Dr. Beaumont on "Digestion," edited by Dr. Andrew Combe; and for fuller information on articles of food to the titles Aliment and Dietetics.

DIGGES, Leonard, an English mathematician, born in the parish of Barham, Kent, died about 1574. He was educated at Oxford, was possessed of an ample fortune, and devoted himself to mathematical studies. He wrote "Tectonicum, briefly showing the exact Measuring and speedy Reckoning of all manner of Lands, Squares, Timber, Stones, Steeples, &c." (1556); *Pantometria*, a practical geometrical treatise (1591); and "Prognostication Everlasting of right good effect, or Choice Rules to judge the Weather by the Sun, Moon, and Stars" (1555).—Thomas, only son of the preceding, died in 1595. He was graduated at Oxford, adopted the profession of a soldier, and was appointed muster-mas-

ter general of the forces sent out by Elizabeth to assist the Netherlands. He wrote several mathematical treatises and other works, among which may be mentioned *Alæ, seu Scalæ Mathematicæ* (1573); "A Letter on Parallax" (1573); "A Geometrical Treatise named Stratioticos, requisite for the Perfection of Soldiers" (1590); "A Perfect Description of the Celestial Orbs according to the most ancient Doctrine of the Pythagoreans" (1592), and some others.

DIGIT (Lat. *digitus*, finger), in arithmetic, one of the 10 figures or symbols by means of which all numbers are expressed. In astronomy, it designates a 12th part of the diameter of the sun or moon. Thus, an eclipse is said to be of 9 digits when three-fourths of the diameter of its disk are concealed.

DIGITALIS, a genus of exogenous plants belonging to the natural order *scrophulariaceæ*. *Digitalis purpurea* (Linn.), purple foxglove, is a small shrub found in pastures and about hedges on banks of streams, in a gravelly or sandy soil. Calyx 5-parted, unequal; corolla campanulate, the limbs obliquely 4-lobed; stamens 4; stigma simple; capsule ovate-acuminate; root of numerous long slender fibres, biennial; stem erect, 3 or 4 feet high, commonly simple roundish with slight angles, downy; leaves alternate, ovate-lanceolate or elliptic-oblong, crenate, downy, rugged, and veiny, of a dull green color, tapering at the base into winged footstalks, lower ones largest; raceme terminal, long, simple, of numerous large, pendulous, odorless flowers. Fuchsius is regarded as the earliest botanist who mentions this plant, which he named *digitalis* (Germ. *Fingerhut*, finger stall), on account of the blossoms resembling the finger of a glove. The term foxe-glove occurs in a MS. *Glossarium Ælfricæ*, written before the Norman conquest, and in a MS. Saxon translation of Apuleius, both of which are among the Cotton MSS. in the British museum; but no Latin or Greek name was given to this plant previous to Fuchsius in 1542. This beautiful shrub derives its chief interest from its medicinal properties, which reside in the leaves and seeds, the latter being small, roundish, and of a grayish-brown color. The effect of foxglove has been tried on dogs, horses, rabbits, turkeys, the domestic fowl, and frogs, and on all it has been found to act as a poison. According to Orfila, the first symptom of poisoning in carnivorous animals is vomiting. The cerebro-spinal symptoms observed in animals are diminished muscular power, convulsive movements, tremors, and insensibility. When given in small doses to man, it is found to exercise a remarkable influence over the circulation, frequently reducing the pulse from 70 or 80 to 40 or 50 beats in the minute. Dr. Baildon found that his own pulse was reduced by the use of digitalis from 110 to 40 beats per minute while he occupied a recumbent position, but upon rising it increased to 70 beats. This action, however, is far from being uniform. Dr. Sanders indeed asserts that its use is invariably attended by an increased action of the pulse. The effects of digitalis more closely resemble those of tobacco than any other agent. It possesses in common with green tea the property of preventing sleep. In medicine it is usually employed: 1, to reduce the heart's action; 2, to promote the action of the absorbents; 3, as a diuretic; and 4, on account of its influence over the cerebro-spinal system. Large quantities of digitalis are exported from Germany to Cuba, where it is mixed with tobacco in the manufacture of cigars.

DIGITIGRADES, the tribe of the typical carnivora, so called because they walk on the ends of the toes, as distinguished from the plantigrades, which, like the bear, place the whole foot upon the ground. This tribe includes the *mustelidæ* or weasels, the *canidæ* or dogs, and the *felidæ* or cats. All have the cheek teeth with cutting edges, the lower shutting within the upper, dividing the flesh of their prey like the blades of scissors. As their food would indicate, they have a simple stomach and a short intestine. Their carnivorous propensity may be measured by the tubercle or heel on the lower carnivorous tooth, and the number of false molars in front and of tuberculous teeth behind it; those having the simplest carnivorous teeth, and the fewest molars in front and behind, like the cats and the weasels, are the most sanguinary. The characteristic marks in the skeleton are the long metacarpus and metatarsus, the elevation of the os calcis, and the shortness of the phalanges which alone rest upon the ground; and in the cats, the retractile claws. The extremities are formed for leaping and springing; from the pelvis as the fixed point, the 3 portions of the limbs are movable in alternately opposite directions; by the simultaneous flexion of these joints, and their sudden extension by means of powerful muscles, the greatest force is given to the spring, the elevated and elongated heel affording the principal mechanical advantage in the digitigrade foot.

DII, the Latin generic name for all the gods. The instinctive tendency of man, prompted also by every thing in the external world, is to believe in a divine agency and government. Amid the grand movements of the universe, and with consciousness of noble passions and faculties, he demands the origin, the law, and the destiny of himself and the objects by which he is surrounded; he asks what absolute masters govern the phenomena of nature, impel the streams, unchain the tempests, illumine and move the skies, guide the procession of the seasons, and start the germs of life. Asia, the birthplace of man, and the theatre of the earliest human societies, gave the first answers to these inquiries, sometimes deifying the elements, the heavenly bodies, and eminent men; sometimes marking the constant antagonisms of nature—how the shore confronts the sea, the wind and ocean wrestle together, and conscience and passion strive for the mastery of the human will—and therefore deifying two opposite principles of good and evil,

either of which would be supreme but for the other; and sometimes attaining the conception of one supreme deity whose spirit pervades all things. The Greek and Roman mythology, though it received some elements from the creations of the East, was mainly the work of the poets and legislators of Greece. Created and professed by the most artistic people of the past, it was submitted to by the triumphant Romans; during many centuries morality found support in it, and misfortune a refuge; philosophy adopted it, and poetry rendered it immortal. The principal divisions of nature were personified into great divinities, and forms, attributes, and a name were given to the smallest objects in the universe. Fable too and tradition become transfigured into mythology, and many of the gods and demigods were but the kings, heroes, and sages who preceded the historical times. Of divinities of various ranks, Hesiod says there were no fewer than 30,000 who inhabited the earth, and to this immense number many more were afterward added. The Romans generally made 3 classes of the gods. The first of these, the *dii majores*, were 12 in number, 6 males and 6 females, and their names are thus combined by Ennius in 2 hexameters:

> Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars,
> Mercurius, Jovi, Neptunus, Vulcanus, Apollo.

These deities corresponded with the 12 Olympian gods of the Greeks, and constituted the divine council which presided over the course of human affairs. The Greeks added to these 12, Alexander the Great as the god of conquests, but he was not recognized as such by the Romans. The second class were the 8 *dii selecti*, Janus, Saturn, Genius, Sol, Bacchus, Tellus, Pluto, Luna, who were sometimes classed with the superior gods. The third class were the *dii minores*, comprehending a crowd of beings to whom limited divine honors were paid, and who were regarded as possessing a species of divine nature. Among these were the indigenous gods, attached to certain places of which they were the guardians, as the *penates* and *lares*, the protectors of home and family. The woods, rivers, fields, mountains, forests, and solitudes were all peopled with fauns, sylvans, satyrs, nymphs, dryads, and hamadryads. The agitation of the air came from the flight of the Zephyrs; the rainbow was the scarf of Iris; sound reverberating through the rocks was the nymph Echo; and all nature under the charm of this mythology became endowed with life and intelligence. There were the implacable Parcæ in collision with the sharply-cut Greek personality; and the avenging Furies, side by side with the more heroic than moral Greek instincts. Some theologians have considered mythology founded upon religious ideas once revealed to man, but, in consequence of length of time and the action of an exuberant imagination, at length overgrown with fable. It was never so native to the Romans as to the Greeks, and before the era of Augustus the faith in it had ceased to be either a strong religious or æsthetic feeling. It was degraded by the apotheosis of impious and monstrous Roman emperors, and passed away as Christianity gradually advanced.

DIJON (anc. *Dibio* or *Divio*), a town of France, former capital of the duchy of Burgundy, now the chief town in the department of Côte d'Or, seat of a bishopric, of a royal court, of tribunals of the first resort, and of a university with faculties of law, the sciences, and belles-lettres; pop. in 1856, 29,766. It is of an oval form, with several suburbs, and lies at the foot of a chain of mountains in a fertile vale, at the confluence of the rivers Ouche and Suzon, on the railway from Paris to Lyons, 160 miles S. E. of Paris. It is generally well built, and has numerous handsome public places and elegant houses. It is enclosed by ramparts, and its environs furnish delightful promenades. Dijon contains many remarkable buildings, the principal of which are the cathedral, formerly the Cistercian abbey of St. Benigne, a massive Gothic edifice founded in 535 and rebuilt in 1271, which contains the magnificent mausoleums of Philip the Bold and of John the Fearless; the church of Notre Dame, built in the 13th and 14th centuries; the church of St. Michael, which dates from the 15th century, remarkable for its front and its castle-like solidity; an ancient castle, the work of Louis XI., which served for a time in the 18th century as the prison of the duchesse de Maine, Mirabeau, and the chevalier d'Eon; the state palace, which contains archives and monuments of the middle ages of great value; and a palace of the princes of Condé, built by Louis XI. and XII. It has also a school of the fine arts, 8 colleges, and 2 libraries, one of which contains 40,000 volumes. Its industry is active and varied, employed in the manufacture of linens, hosiery, vinegar, and candles, in distilleries and bleacheries, and in commerce in grain and wines. The origin of Dijon is traced back to times preceding the Roman dominion. Under Marcus Aurelius it was surrounded by walls flanked with towers, and was embellished and enlarged by Aurelian. It was burned by the Saracens in the 8th century, and sacked by the Normans in the 9th. It was again ravaged by fire in 1127, and was for 3 centuries the residence of the dukes of Burgundy and the seat of their brilliant court. By them its present fortifications were constructed. In 1513 it was besieged by the Swiss, and saved itself only by a humiliating treaty. It is the birthplace of some of the most eminent men of France, of Bossuet, Crébillon the elder, Piron, Rameau, Longepierre, Lamonnoye, Cazotte, Guyton-Morveau, and the duke of Bassano.

DIKE, in geology, a wall of trap or other igneous rock, which traverses other rocks, and appears to have been produced by the flowing of melted matter into a deep rent or fissure. Dikes are distinguished from veins by the greater uniformity of their contents, by the parallelism of their sides, by their not ramifying into smaller veins, and by their usually larger di-

mensions. The name was given them from their frequently projecting above the surface like a wall, owing to the degradation of the softer rock around them, dike being in the north of England and in Scotland a provincial name for wall. They are met with from a few inches to more than a mile in thickness. In volcanic eruptions they are seen in process of formation, as deep rents open and are filled with liquid lava. In the English coal mines trap dikes are occasionally met with in underground operations. They there form a wall across the line of the coal beds, cutting them off, and causing them at times to be thrown out of place. In the United States they occur likewise in the gold mines of North Carolina and in other metalliferous districts.—The term is also used to denote a ditch, and is probably derived from the word to dig; but as applied to a sea wall or embankment, it comes no doubt from the Dutch word *dijk*, of the same signification. Such earth works were in former times a common means of defence, and were built around castles and fortresses. In Holland are the most remarkable dikes in the world, constructed to prevent the overflow of the lands reclaimed from the sea. Their immense importance may be appreciated from the fact that a single inundation from the sea in the year 1277 caused the destruction of 44 villages; and in 1287, only 10 years afterward, 80,000 persons were destroyed by another, and its present extent and shape were given to the Zuyder Zee. In the 15th century about 100,000 persons were again destroyed through the imperfection of the dikes, when their construction was undertaken in the most thorough manner, and a law was enacted enforcing their being kept in order. At present this work is conducted on a systematic plan and at great cost. Embankments are made toward the sea with heavy timbers filled in with stone, and the surface is covered with bundles of flags and reeds fastened down by stakes. Piles also are driven into the sand, and protected by planking as well as by earth, turf, and stones. These artificial dikes are often 40 feet above ordinary high water, and wide enough at top for a common roadway. Frequently the slopes are covered with wicker work made of willow twigs, and the willow tree is extensively cultivated to furnish these supplies, which require frequent renewal, as also to bind together by its roots the loose sands. Walls of masonry are built in some of the most exposed situations, and rows of piles outside protect the dikes from the action of the waves. It is estimated that the annual expense of keeping up the dike of Helder and that of West Cappel, at the western extremity of the island of Walcheren, is about $30,000 each. The whole expenditure in Holland for maintaining its dikes and regulating the water levels is annually from $2,000,000 to $2,500,000. Engineers are constantly employed, and every provision is made of materials that may be required for immediate repairs. Watchmen are employed during the winter months to patrol the dikes by day and night, and give alarm whenever the danger appears imminent and the tide threatens to overflow. The people then hasten to the point, and by mats of straw and rushes and large sheets of sail-cloth buried in the sand they raise a temporary bulwark, to be more securely built before the approach of the next tide.—Dikes are often constructed as barriers for reservoirs of water, and for this purpose they are built on several well established plans. The loose materials excavated for the channel or basin are piled up in a firm bank and consolidated by rolling with heavy rollers. Sometimes they are rendered more secure by building within them along their central line a puddle bank of selected clayey earth, mixed with sufficient sand to give it tenacity, so as not to crack in drying. This should be carried down to a solid foundation, and may be advantageously bedded upon a layer of concrete. It is built up a little later than the bank on each side of it, and both are rolled on the addition of every layer of 6 inches with a heavily ribbed roller of cast iron. The use of any material of the nature of quicksand is to be carefully avoided in any part of the embankment. Next the water it is well to face the work with a layer of broken stone that will pass through a 2 inch ring, and over this should be laid a sloping wall of flat stone at an inclination of 1 base to 1 vertical, or from that to one of 3 base to 1 vertical. The broken stone within is a guard against the embankment being penetrated by any small water animals. The dike around the great reservoir of 106 acres in the central park, New York, is made on the plan given above, which is approved by the engineers of France and England. It is 16 feet 8 inches wide at top, with an inner and outer slope of 1½ base to 1 vertical. The puddle bank of clay in the centre, which reaches to within a few feet of the top, is 16 feet thick. The depth of water around the margin is 34 feet. At the surface of the water the thickness of the embankment is 24 feet 9 inches, and at 30 feet below it is 114 feet 9 inches. The French engineers give the preference to this mode of construction to that of a wall of masonry alone or of an embankment within a wall. Stone work by settling is liable to injury that can be repaired only at great cost, especially if the structure be concealed within an embankment. Where room is an object, as in the streets of a city, the outer sides of the dike are conveniently held up by steep walls of stone, the object of which is neither to add to the strength nor to the impermeability of the work.

DILETTANTE (pl. *dilettanti*), an Italian term, naturalized in France, England, and Germany, signifying an amateur, and applied to a person who especially interests himself in any art, without knowing its fundamental principles, and without making it an object of thorough study. The term dilettante designated originally a lover of Italian vocal music, and was at one time the name of a party which maintained the

superiority of that music. In England, a society called the "Dilettanti Society" was originated in 1760, by gentlemen who had travelled in Italy, at first for social purposes; but it afterward acquired celebrity by devoting its funds to the encouragement of the study of classical art, by sending out travellers, and by publishing books on antiquarian subjects.

DILKE, Charles Wentworth, an English journalist, born Dec. 8, 1789. He was graduated at Cambridge, and became employed in the navy pay office, where he remained 20 years. During this time he had contributed largely to the "Westminster Review," the "Retrospective Review," and other periodicals of note. In 1830 Mr. Dilke became editor of the "Athenæum," which, from having been but very partially successful under its original proprietors, Mr. James Silk Buckingham and Mr. Stirling, speedily rose to the rank it now holds in English periodical literature. He not only improved its quality, but diminished its cost to the public; it had formerly been sold for 1*s.*, but Mr. Dilke reduced the price to 4*d.* In 1846, having intrusted the editorship of the "Athenæum" to Mr. Thomas Kibble Hervey, Mr. Dilke undertook the editorship of the "Daily News," a large newspaper which had recently appeared under the auspices of Mr. Charles Dickens. With the coöperation of Mr. Dilke, and the application by him of the principle of reduction in price, the success of the "Daily News" was very remarkable. In the second year of its existence more than 12,000 copies were printed. This prosperity speedily and permanently declined, however, on the surrender of the editorship by Mr. Dilke in 1849—a decline accelerated also by a mistaken resolution on the part of the new director to increase the price. The consequence was a reduction of the issue to 4,000, which it has not since exceeded. —Charles Wentworth, son of the preceding, born in London, Feb. 18, 1810. He was graduated and studied law at Cambridge, but did not during that time contribute, as he is reputed to have done, to the columns of the "Athenæum." He manifested early that bias for the conduct of industrial and artistic organization, the development of which in subsequent enterprises has proved a source of public benefit, and of honor to himself. In 1844 he submitted to the society of arts, of which he was a member, and is now the vice-president, a plan for the exhibition of English industrial products, which contained the germ of the idea more fully realized in the universal exhibition of 1851. A commission of inquiry was instituted to ascertain the measure of assent and coöperation that might be expected for the project from various quarters, but met with little encouragement. Mr. Dilke persisted in his endeavors, and, in conjunction with Mr. Henry Cole and Mr. Scott Russell, presented his original plan to Prince Albert, president of the society of arts; and after combating various obstacles, he had the gratification of seeing it realized in the exhibition which took place in the apartments of the society in 1846, and which was renewed in the following year. Among many tokens in recognition of his labors received by Mr. Dilke, was his appointment by Prince Albert as a member of the royal commission, in which capacity until his resignation he rendered important service. For this it was desired to bestow upon him some special acknowledgment, but as he constantly refused proffers either of honor or emolument, the queen forwarded to his wife a bracelet of diamonds. In 1853 he was a British commissioner to the industrial exhibition in New York.

DILIGENCE, a kind of stage coach drawn by from 3 to 6 horses, which was the principal public conveyance in France before the introduction of railways, and which is still in use in many parts of Europe. The French 4-wheeled diligence is composed of 3 compartments. The front division (*coupé*) is the most expensive, and holds 3 persons. The middle division (*intérieur*) accommodates 6 persons at a lower rate. Behind the inside is the *rotonde*, a much less comfortable place, which affords the same number of seats at a still lower rate. There is also room for 4 persons including the conductor on the roof over the *coupé* (*banquette* or *impériale*), which is the cheapest place. With a full number of persons the diligence weighs about 5 tons, exclusive of baggage. The Spanish and Italian diligences are superior to the French. The German diligences (*Postwagen*, *Eilwagen*) are attached to the post office; so are those of Switzerland. In Russia diligences are built with a succession of *coupés*, each capable of containing 2 or 3 passengers; others have 2 or 3 *coupés*, and then a *rotonde* holding 4 persons. The conductor's seat is in front, and beside him sits the *yamtchik* (post boy); the number of horses is generally 4, harnessed abreast, but to these 2 leaders are frequently added, and on the off horse sits another post boy.

DILL, the common name of the *anethum graveolens* (Linn.), an annual plant of the natural order of the *umbelliferæ*, a native of Spain, but naturalized in the south of France and Germany. It has an upright smooth stem, much dissected leaves, yellow flowers, and small oblong seeds, with sharp, filiform dorsal ridges. It is cultivated for the carminative and stimulant properties of its seeds. They are imported in large quantities from the south of France into England, where, beside their medicinal use, they are employed in the manufacture of British gin. In Germany they are used in pickling cucumbers and in the manufacture of sour crout.

DILLENIUS, Johann Jakob, a German botanist, born in Darmstadt in 1687, died in Oxford, April 2, 1747. Following a not uncommon German custom of the time, each generation of his family added some letters to their name, his grandfather being called Dill, his father Dillen, and himself Dillenius. He studied at the university of Giessen, and was received a member of the society of "Inquirers into Nature," under the auspices of which he published a "Disser-

tation upon the Plants of America naturalized in Europe;" a "Treatise upon Coffee," with an account of the seeds which might displace it, giving the preference to burnt rice; and a volume of "Observations upon the Mode of Development of Ferns and Mosses," in which he confirmed the theory of different sexes in plants. He first obtained a reputation among naturalists by his "Catalogue of the Flora of Giessen," published in 1719. The great merit of Dillenius as a botanist consists in a constant attention to the discrimination of the genera by the parts of the flower and fruit, a principle of classification first proposed by Gesner and which became the foundation of the system of Linnæus. William Sherard, a scientific English traveller, succeeded in persuading Dillenius to leave Germany for England. He arrived in London in 1721, and had a rich garden at Eltham placed at his disposition by James Sherard, a brother of William. He edited an enlarged edition of Ray's "Synopsis of British Plants," which he enriched with engravings of his own. In 1728 William Sherard died, and founded by his will a chair of botany at Oxford, to which Dillenius was appointed, who in 1732 published his *Hortus Elthamensis*, containing not only descriptions of plants arranged in alphabetical order, but also 324 plates engraved by himself on pewter. This work was enthusiastically received by his contemporaries, among others by Linnæus, then commencing his labors. In 1741 he published his "History of Mosses," his greatest work, which places him in the first rank of the botanists of the last century. He was more than 20 years in collecting the materials of this work, which is a noble monument of acute discrimination and minute research. The plates, numbering 85, and the descriptions were all by his own hand. He published no subsequent work, but many of his drawings and collections are preserved in the Sherardian museum at Oxford. The isolation which the labors of Dillenius required affected his social qualities. He thought only of his own knowledge and opinions, and believed himself the prince of botanists. Linnæus visited him in 1736, and implicitly adopted some of his faulty views in opposition to his own better judgment; and the subsequent correspondence between these two naturalists shows a polite condescension on the part of the Swede to the pretensions of the Oxford professor. Linnæus dedicated to Dillenius a magnificent genus of plants of tropical India, which is the type of the family of the *Dilleniaceæ*.

DILUVIUM, Drift, Bowlder Formation, the deposits of clay, sand, gravel, and bowlders spread over the surface of the polar regions and adjacent portions of the temperate zones. For a time these deposits were confounded with those called alluvial, and when it was seen that they could not have been produced by the action of existing currents, their origin was commonly referred to the Noachian deluge. As the extent, depth, and nature of the materials constituting the formation came to be better understood, this opinion, too, was necessarily abandoned; for it was apparent that no transient deluge could have produced effects so vast as those exhibited in this formation. In the northern hemisphere the drift is found in Europe, Asia, and America, extending from the polar regions toward the equator, and disappearing on the continent of North America about lat. 38°. In Europe, all trace of it is lost in the countries bordering the Mediterranean. Its distribution southward on the two continents appears to accord with the deflections of the present lines of equal winter temperature. In South America it is recognized in Patagonia, and traced from Cape Horn to lat. 41° S. Throughout these regions the features of the formation are the same. The surface is irregularly covered with the deposits above named. Sometimes they are so arranged in strata as to indicate that a long time has been occupied in their deposition; while occasional marine shells, nearly all of recent species, testify to tranquil action in the localities where they are met with, and to an epoch of production closely approximating to the recent period. The superficial strata of sand and gravel are found at times 300 feet or more in thickness. They rest upon geological formations of all ages up to the beds of older pliocene, such as the mussel and clam beds found at Augusta and Gardiner in Maine, 60 feet beneath the sand and gravel, and filled with shells scarcely distinguishable from those in our harbors. The drift is met with upon the summits of high mountains; it is seen 3,000 feet above the level of the Baltic, and upon the highest points of the Grampian hills, 4,000 feet above the sea. Everywhere the formation is characterized by loose masses of rock scattered over the surface, more or less rounded in form, and differing from the solid ledges beneath them. As already described in the article Bowlder, they are often of great dimensions, and their sizes increase as they are traced toward the pole to their parent beds. In Russia they have thus been identified with ledges more than 800 m. distant toward the north. Bowlders of the same kind of granite, easily recognized, traced from Moscow to St. Petersburg, vary from 2 to 3 feet in diameter at the former to as many yards at the latter point. Instances of these phenomena are everywhere to be seen in the northern United States. In southern Wisconsin pieces of native copper were often found in the superficial deposits long before the mines of this metal were discovered on the S. shore of Lake Superior, 300 m. to the north. The N. shores of Long island are strewn with bowlders of red sandstone, and of granite and other primary rocks, arranged in groups which correspond with the position of the ledges of the same rocks in Connecticut, across the sound to the north. So on the European continent, the stratified rocks of which the whole region on the S. side of the gulf of Finland is composed, are covered with granitic bowlders from the primary region of Scandinavia on the other side of the gulf. The surface

of the bowlders is often found to be striated and grooved, as if worn by hard rubbing over rough surfaces; but sometimes it is smooth and almost polished. The solid ledges of rock when exposed to view very frequently display a similar grooved and worn surface. The furrowed lines, called diluvial scratches, are sometimes seen in 2 sets, one much fainter than the other, the 2 crossing each other at a sharp angle. Their general direction is that in which the bowlders are traced to their parent ledges. In the northern states this is usually from S. S. E. to N. N. W. Upon the slopes of high lands greater abrasion and grooving are observed on the N. than on the S. sides; but if these elevated tracts were opposed to a great current, they do not appear to have had the effect of diverting this from its course, except it may have been in the great valleys of drainage, where the striæ have been observed in some instances to coincide with their direction. The bowlders in an open country are usually scattered about without regularity, but in some localities they are traced in long, narrow, and well defined belts, which cross the summits of ridges in lines oblique to the direction of these. That all parts of the region covered with drift did not occupy their present elevation at the time its deposition took place, is proved by the deposits of clay containing marine shells found in many localities in New England and New York, reaching at a maximum about 500 feet above the present level of the sea, and overlaid by the sand and gravel of the drift. The valleys of the St. Lawrence and of Lake Champlain were thus depressed, and the waters of the ocean must at that time have reached the basin of Lake Ontario. Some regard this as evidence that all the neighboring territories now covered with drift were similarly submerged, but such beds of shells are only met with in the valleys named and in certain localities not far removed from the present margin of the sea. Sir Charles Lyell observes of the drift fossils of Canada found near Montreal and Quebec, and of those of Scotland, that they are of species indicating a colder climate than now belongs to the regions in which they are found. He also noticed near Upsal in Sweden, in a ridge of stratified diluvial sand and gravel, a bed of marl 100 feet above the present level of the gulf of Bothnia, containing myriads of the peculiar forms of shells still common to the brackish waters of the Baltic, and which must have originally formed the bottom of the sea before the distribution of the bowlders; for upon the top of the ridge are several huge blocks belonging to the drift. He hence infers that the transport of the bowlders continued after the sea was inhabited by existing testacea, and after the continent had assumed its peculiar configuration, by which the Baltic is separated from the salt waters of the North sea, and the gulf of Bothnia is made to have only ¼ the saltness of the ocean. The shells found in the drift refer the period of its production to a time subsequent to the pliocene epoch. It preceded the extinction of the *mastodon giganteus*, for the bones of this animal are exhumed in New Jersey and New York from bogs in the surface of the drift, where they have lain undisturbed, not separated even from the decayed contents of the stomach of the animal, since life departed from them. With the remains of the mastodon occur several species of fluviatile shells, such as now live in fresh water. The deposit containing these and also well preserved mastodon bones is identified on both sides of the great chasm of the Niagara valley, in situations where it could only have been formed before this chasm was in existence. Thus, according to the calculations of Sir Charles Lyell, the period of production of the drift formation cannot approach within some 30,000 years the time commonly assigned for the introduction of the human race upon the earth.—Various theories have been devised to explain the phenomena of the drift. Under date of Nov. 21, 1825, Mr. Peter Dobson, of Vernon, Conn., addressed a short communication to Prof. Silliman, making a page of the 10th vol. of the "American Journal of Science" (1826), which, as remarked by Sir R. I. Murchison in his address before the geological society of London in 1842, contains the essence of the modified glacial theory since arrived at after much debate, and a previous acquaintance with which might have saved volumes of disputation on both sides of the Atlantic. Mr. Dobson describes the appearance of the bowlders abraded and scratched, "as if done by their having been dragged over rocks and gravelly earth in one steady position," and adds: "I think we cannot account for these appearances, unless we call in the aid of ice as well as water, and that they have been worn by being suspended and carried in ice over rocks and earth under water." The transportation of masses of rock by icebergs as they drift along the currents which set from the polar regions, and the distribution of their loads over the bottom of the ocean as the bergs melt away, present, in the view of many, a repetition of the process by which in remote times the surfaces of the present continents were covered with the drift materials. Lyell supposes that the lands, with their present irregularities of surface already defined, were slowly submerged, while islands of floating ice passed along in the polar currents, grounding on the coast and on shoals, and pushing forward the loose sand and gravel spread over the bottom. Thus abraded down to the solid rock, and the surface of this grooved and striated, the shoals by continued subsidence passed down to great depths, where the loose materials gathering upon them were no longer disturbed. Finally he supposes the direction of the movement to have been reversed, and the bottom of the ocean to have been again raised to form dry land; and that during its reëmergence the arrangement of the materials which cover it was modified by exposure to the distributing and stratifying action of the waves, tides, and currents. The dearth of fossil shells in the clays of

the drift would be accounted for under this hypothesis by the unfavorable influence of the icebergs on the growth of the testacea in the shallow waters frequented by them, while in other parts of the ocean the depth would be too great for their existence to be possible. The extent and immense number of modern icebergs seem to prove their capacity to reproduce upon the shoals and over the bottom of the Atlantic nearly all the phenomena of the drift formation. Measured as they are by miles in length, and rising at times more than 300 feet in height, with only $\frac{1}{5}$ of their bulk then visible above the water, they may well float off and distribute along their track the largest bowlders which they have abstracted from the rocky cliffs down which they moved as glaciers into the sea. So extensive are these floating ice islands that they have been mistaken by those travelling upon their surface for the solid continent; and one has been known to be aground where the soundings gave a depth of 1,500 feet of water. Urged on by the broad current in which they float, such masses must exert an enormous power upon obstacles presented to their progress. Where they rub upon the bottom, this must be worn and grooved in parallel furrows on the line of the straight course of the berg, and other sets of scratches would be produced by succeeding bergs, which might deviate slightly by a different slant of the current, or possibly by the effect of a strong wind upon the floating mass, from the exact bearing of the former set. The chief objection to the theory of the distribution of the drift by icebergs is, that no evidence is furnished of the great body of lands covered with this formation having been submerged immediately before or at the time of its deposition. The beds of clay containing marine shells, found on the borders of the St. Lawrence and Lake Champlain, and in other localities near the coast, are not traced into the hills of the interior, nor to elevations exceeding 500 feet above the level of the sea. In the strata of other formations, even of the most ancient periods, the occurrence of marine fossil shells affords unmistakable evidence of the locality having been covered by the ocean; but in this instance this familiar proof is wanting over areas of vast extent, large portions of which have been carefully explored by the most critical observers. It is disputed that icebergs could produce the parallel scratches on the rocks; and it is contended that if the northern part of the continent were beneath the sea, the effect would be to mitigate the coldness of the climate, and render this unfavorable for the required production of icebergs. It is also objected that the extent to which the bowlders are commonly traced from their parent ledges upon the North American continent is usually limited to from 20 to 200 m., while the bergs which now drift from northern seas bring the stones with which they are charged from 1,000 to 2,000 m.; and that, moreover, they travel a very circuitous route, the currents changing their course with the irregularities of the coast line, and counter currents giving diverse directions to the modern drift, while the distribution of that of ancient times was remarkably uniform in its direction. It is, however, impossible to show that the contour of the ancient continents was incompatible with the existence of more uniform currents than those of modern seas; and in the diluvium of Scandinavia and Russia the transportation of the bowlders appears to have been over nearly as many degrees of latitude as are traversed by modern icebergs.—Another class of natural agents are observed to be in operation, producing effects similar to those witnessed in the drift. These are the glaciers, vast accumulations of ice, which gather in elevated regions, and are slowly and irresistibly pushed down to lower levels. In their progress they score and groove the surface over which they pass, and rend masses of rock from the cliffs, moving the fragments forward, and finally leaving them rolled in the shapes of bowlders, and grooved by the rubbing to which they were subjected when fixed in the ice. In the Alpine regions of Europe the effects thus produced are so remarkable, and spread over such extensive districts, that eminent geologists who have made them their study have been disposed to refer all the phenomena of the drift to the action of glaciers; and in this disposition they have been confirmed by finding unmistakable evidence of the extent of the glacial action from the Alps having in former periods reached full 50 m. beyond their present limits. The researches of the late Dr. Kane have made us acquainted with a field in which these operations are now going on upon the grandest scale. Nearly the whole interior of Greenland, a continent in itself, appears to be covered with one broad glacier. From its edges, extending many hundred miles along the northern seas, its fringe is ever falling in vast masses of ice and rock into the deep waters to be floated off as icebergs, while from the interior the great field itself is slowly urged on in portions following the same unvarying directions. Such phenomena furnish an explanation for several examples of diluvium, which do not admit of reference to the drifting of icebergs in a polar current. In the extreme northern part of Lapland, for instance, the distribution of the bowlders appears to have been from the interior toward the White sea and the Arctic ocean. But geologists are far from generally admitting the probability that the large portions of the earth's surface now covered with the drift formation were ever in a condition to have been under the action of glaciers moving in one general direction; nor does it appear necessary to have recourse to them, when icebergs are now producing analogous effects, and upon a scale commensurate with the ancient distribution of the drift.—Beside these explanations to account for the phenomena, drawn from operations now going on, the extent of which we can investigate, and in some measure appreciate, a third hypothe-

sis has been advanced by the Professors Rogers, which also appears to have been adopted by Murchison. Rejecting the supposition "that the cutting fragments and particles were ever pressed upon by ice, it appeals to the enormous erosive power which a thick and ponderous sheet of angular fragmentary rock would possess if driven forward at a high velocity under the waters of a deep and general inundation, excited and kept in motion by an energetic upheaval and undulation of the earth's crust during an era of earthquake commotion." By the uplifting of the floor of an arctic sea, accompanied, it may be, by an equal subsidence of the country south, a mass of water is conceived to be converted by earthquake pulsations into a series of stupendous and rapidly moving waves of translation. These, helped on by the still more rapid flexures of the floor over which they move, are considered to be agents adequate to produce the results exhibited in the phenomena of the drift formation. Dr. Whewell, recognizing the wave of translation as a mechanical agent, cautions against its being regarded as a current which flows continuously. Its effect must be to carry a single mass along with it at its own velocity, or to give a transient motion to a series of masses in succession as it passes over each, moving each but a small distance. A series of waves, each produced by some paroxysmal action, would mathematically account for any amount of result. He presents some simple numerical calculations, in which the quantities, it is true, are hypothetical, and which as they are modified would proportionately modify the result by which he arrives at the conclusion that a sea bottom 450 m. long, 100 m. broad, and 500 feet below the surface of the water, raised either at once or by paroxysmal lifts, would produce waves of translation with an effect equivalent to the dispersion of the whole body of northern drift.

DIME (Fr. *dîme*, contraction of *dixième*), a silver coin of the United States, of the value of 10 cents, or $\frac{1}{10}$ of a dollar. It was first coined in 1796 in pursuance of the act of April 2, 1792, though pattern pieces were struck in 1792. Its legal standards have been as follows: by act of April 2, 1792, fineness 892.4 thousandths, weight 41.6 grains; by act of Jan. 18, 1837, fineness 900 thousandths, weight 41¼ grains; by act of Feb. 21, 1853, fineness 900 thousandths, weight 38.4 grains. (See Coins.)

DIMSDALE, Thomas, baron, an English physician, born in Theydon-Garnon, co. of Essex, in 1712, died in Hertford, Dec. 30, 1800. He was especially noted for his zeal in promoting inoculation for the small pox, his success in which caused him to be invited to Russia by the empress Catharine II. in 1768, for the purpose of inoculating herself and her son. Catharine rewarded him with the title of baron and large presents. He afterward visited Frederic II. of Prussia, at Sans-Souci, and then returned to England, where, in 1776, he published a treatise on inoculation, which was translated into all the European languages. In 1780 he was elected to the house of commons, and in 1781 made a second professional visit to Russia. Beside the treatise above mentioned, he published several pamphlets on the same subject.

DINAGEPOOR, or Dinajpore, a district of British India, under the lieut. gov. of Bengal, bounded N. E. by Bootan, between lat. 24° 53′ and 26° 38′ N., long. 88° 2′ and 89° 16′ E.; length from N. to S., 130 m.; breadth, 75 m.; area, 3,820 sq. m.; pop. 1,200,000. It is a level country, watered by the Teesta and a vast number of other streams, and fertile in rice, pulse, oil seeds, pepper, ginger, turmeric, coriander, capsicum, potatoes, plantains, many other esculent vegetables, and the sugar cane. Small quantities of wheat, barley, tobacco, and a poor kind of cotton, are also produced. Silkworms are extensively reared.—Dinagepoor, the capital of the district, is a clean but ill-built town, on the river Purnabada, 261 m. N. from Calcutta, and the residence of the British authorities; pop. about 25,000.

DINAPORE, a town of British India, in the district of Patna, lieut. governorship of Bengal, on the right bank of the Ganges, 10 m. W. from Patna and 411 N. W. from Calcutta; pop. about 16,000. It is an important military station, noted for its handsome and extensive cantonments. On July 25, 1857, a mutiny occurred here which, though attended with little immediate bloodshed, was one of the most mortifying and serious disasters which befell the British during that year. The garrison consisted of 3 full native infantry regiments, beside a European field battery and parts of the 10th and 37th European foot, commanded by Gen. Lloyd. When symptoms of revolt became unmistakable, this officer took the weak precaution of removing the percussion caps from the armory to the officers' mess-room, and then requiring the sepoys to give up the caps already issued. The latter order was resisted, and when the British troops were called out to enforce it, the rebels were seen running at full speed across the fields with their arms and accoutrements. They laid siege to Arrah, attached themselves to the notorious Koer Singh, and gave great trouble throughout the revolt. No pursuit of them was made until the 27th, when an effort to relieve Arrah terminated with great loss to the British. Gen. Lloyd, who had served with distinction, but was now far advanced in age, fell into disgrace on this occasion, and was superseded by Sir James Outram.

DINDORF, Wilhelm, a German philologist, born in Leipsic in 1802. In 1819, at the age of 17, he published a continuation of the commentaries on Aristophanes begun by Beck. In 1828 he was appointed professor of the history of literature in the university of Leipsic, but resigned this office in 1833. He has edited Demosthenes, Æschylus, Sophocles, Euripides, Aristophanes, &c., for the university of Oxford; also many works published at Paris and Leipsic.

DINGELSTEDT, Franz, a German poet, born in the Hessian village of Halsdorf in 1814. He

made himself first known in literature by a publication of poems in 1838, which was followed by a series of novels, without, however, winning much reputation until 1840, when his *Lieder eines kosmopolitischen Nachtwächters* appeared. Since then he has published a great variety of poems, tales, books of travel, &c., among which his *Gedichte* (Stuttgart, 1845) are the most successful. In 1850 he was appointed director of the royal theatre at Munich on account of the success of his tragedy *Das Haus des Barneveldt*. His attention was probably drawn to the stage by Jenny Lutzer, the Viennese prima donna, who became his wife in 1844.

DINKA, Denka, or Donka, a district of eastern Soodan, Africa, between lat. 9° and 12° N., extending along the right bank of the Bahr-el-Abiad, or White Nile, which separates it from the territory of the Shillooks, S. W. of Sennaar and N. of the river Sobat, which separates it from the land of the Nuehrs; the eastern boundary is unknown. It consists of a low and marshy plain, subject to frequent inundations, and containing but few isolated mountains, among which is the Jebel Niemati, or mountain of the Dinkas. A number of long swampy islands covered with reeds and a dense growth of creeping plants, which extend along the right bank of the Bahr-el-Abiad, are described as forming a barrier against invasion from that quarter on the W. boundary. The shores present magnificent scenery, being lined with tamarinds, creepers of a large species, and the lotus shining in great numbers like double white lilies. The inhabitants, called Dinkas, are a savage and ugly race of negroes. They are said to worship the moon, and never to commence warfare when that luminary is above the horizon. They are ruled by chiefs and a king, and have a city on the Bahr-el-Abiad.

DINORNIS (Gr. δεινος, terrible, and ορνις, bird), a gigantic extinct bird, whose bones have been found in New Zealand. The history of this genus, established by Prof. Owen, is one of the most remarkable examples of the correctness of the great laws of the correlation of parts so beautifully elaborated by Cuvier. In vol. iii. of the "Transactions of the Zoological Society of London," p. 29, is the first paper by Owen on this subject. He had received from New Zealand a fragment of a femur, 6 inches long, and with both the extremities broken; from its texture and size he concluded that it belonged to a bird of the struthious order, but heavier and more sluggish than the ostrich; the bone was not mineralized, and retained much of its animal matter, though it had evidently remained in the ground for some time; this was in 1839. In a 2d memoir (p. 235), communicated in 1843, he gives descriptions of portions of the skeletons of 6 species of a struthious bird, which he called *dinornis*, which appeared to have become extinct within the historical period in the north island of New Zealand, as the dodo had in Mauritius; these specimens, 47 in number, had been sent to Dr. Buckland by the Rev. Mr. Williams, a missionary long resident in New Zealand, whose letter states that they were taken from the banks and bed of fresh-water rivers, buried only slightly in the mud, and probably quite recently; that the birds formerly existed in considerable numbers, and must have attained during a very long life a height of 14 or 16 feet. The bird to which these bones belonged was called *moa* by the natives. The names given by Owen were *dinornis giganteus*, height at least 10 feet; *D. ingens*, 9 feet; *D. struthoides*, 7 feet; *D. dromioides*, 5 feet; *D. didiformis*, 4 feet; and *D. otidiformis*, of the size of the great bustard. From these specimens he inferred that the wings were quite rudimentary; that the large cervical vertebræ supported a powerful beak; and that its strong legs were used in scratching up the soil to obtain the nutritious roots of the ferns which are so characteristic of those islands. He draws a portrait of this gigantic bird, the highest living form in that part of the globe, with no terrestrial mammal to contest its possession of the soil before the arrival of the first Polynesian colony. Such large and probably stupid birds, without the instinct or perhaps the ability to escape or defend themselves, would soon become extinct under the persecution of man, whose sole aim would be to obtain a supply of animal food from such easy prey; the diminutive *apteryx* would escape for a longer period, but even this is almost on the point of extinction. In a 3d memoir (p. 307), read in 1846, an examination of a larger number of specimens confirmed the deduction as to the rudimentary condition of the wings by the discovery of a keelless sternum; showed that the species of this essentially terrestrial genus were heavier and more bulky in proportion to their height, more powerful scratchers, and less swift of foot than the ostrich, but in different degrees according to the species; and indicated an affinity to the dodo in the shape of the skull, with a lower cerebral development, and consequently greater stupidity. He formed a new genus, *palapteryx*, of the species *ingens* and *dromioides*, characterized by a posterior or 4th toe, the 3 of the *dinornis* all being anterior toes; he added the 3 new species, *D. crassus*, *D. casuarinus*, and *D. curtus*, all of small size. In a 4th paper (p. 345), read in 1848, he establishes a new genus, *aptornis*, in which he places what he formerly called *D. otidiformis;* this has a large surface for the hind toe, a strong perforated calcaneal process, and a more posterior position of the condyle for the inner toe; it resembles the *apteryx* in the comparative shortness of the metatarsus. In this he describes perfect skulls and beaks of these birds, from which he concludes that the *dinornis*, though resembling the *struthionidæ* in the extraordinary development of the legs and the rudimentary condition of the wings, does not come very close to any existing struthious birds in its adze-like beak, crocodilian cranium, form of the pelvis, and proportions of the metatarsus. The genus *palapteryx* belongs to the *struthionidæ*, being in

some respects intermediate between *apteryx* and *dromaius*. The law of the geographical localization of animals, so remarkably illustrated in the recent progress of geology, receives an additional confirmation by this occurrence in the river banks of New Zealand of remains of gigantic birds allied to the small species still existing only in the same islands. In vol. iv. of the "Transactions" (p. 1), in 1850, the feet and the sternum are described, and 2 new species are alluded to, viz.: *D. rheides*, and *P. robustus;* further descriptions of the skull, beak, and legs are given on pp. 59, 141, of the same volume. Some years before the discovery of these bones in New Zealand, attention had been drawn to remarkable impressions in the new red sandstone of the Connecticut river valley, in Massachusetts, which were believed to be footprints of birds, the largest of which must have exceeded the ostrich in size. Geologists were unwilling to admit the existence of birds at this remote epoch on the simple ground of these tracks, and did not dare to construct even in imagination a bird of such stupendous size as would be required for the largest footprints. But the subsequent discovery of *D. giganteus* demonstrated the existence of birds, at a comparatively recent period, whose tracks would have been larger than the fossil impressions; these recent birds would have made tracks 22 inches long and 6 wide, considerably larger than those of the Connecticut valley. The occurrence of these gigantic birds in New Zealand, with their wingless bodies, and reptile-like condition of the respiratory apparatus (from the non-permeability of their bones to air), adds much to the evidence that similar apterous and low-organized birds existed in America during the red sandstone epoch, "the age of reptiles," when the cold-blooded and slow-breathing *ovipara* exhibited such various forms and so great a number of species. It has been suggested by Prof. Owen that New Zealand may be the remnant of a large tract over which the struthious family formerly ranged; he says: "One might almost be disposed to regard New Zealand as one end of a mighty wave of the unstable and ever-shifting crust of the earth, of which the opposite end, after having been long submerged, has again risen with its accumulated deposits in North America, showing us in the Connecticut sandstones of the permian period the footprints of the gigantic birds which trod its surface before it sank; and to surmise that the intermediate body of the land-wave, along which the *dinornis* may have travelled to New Zealand, has progressively subsided, and now lies beneath the Pacific ocean." (*Op. cit.* vol. iii. p. 328.) Though many of these bones are apparently of recent date, and though it is not impossible, in the opinion of some, that the *dinornis*, like the *apteryx*, may still exist in the interior of these islands, they belong to a certain extent to the class of extinct genera. Dr. Mantell thinks they belong to a period as remote, in relation to the surface of New Zealand, as the diluvium containing the bones of the Irish elk, mammoth, &c., to that of England; and that the last of the moas was destroyed by the earliest inhabitants of New Zealand, as the dodo was extirpated by the Dutch colonists of Mauritius, and the Irish elk by the early British and Celtic tribes. In a more recent paper in the "Proceedings of the Zoological Society," for April 8, 1856, Prof. Owen describes the *D. elephantopus*, the most extraordinary of all for the massive strength of the limbs, and the general proportions of the breadth and bulk to the height; he states it to be the opinion of Mr. Mantell that this species existed in the middle island with the first Maori natives. From a consideration of these species, it appears that those of the north island were distinct from those of the south; Cook's straits proved an insurmountable barrier to birds which could not fly, and could hardly, if at all, swim.

DINOTHERIUM (Gr. δεινος, terrible, and θηριον, animal), an extinct pachyderm of immense size, whose bones have been found in the middle tertiary or miocene deposits of Europe, Asia, and Australia. A few teeth were found in France during the last century, and the early part of the present. In 1829 Prof. Kaup discovered in the sands of Eppelsheim a sufficient number of bones to lead him to form a new genus for this, the largest of terrestrial quadrupeds. Cuvier thought it allied to the tapir from the character of its premolar teeth, and many writers, and among them Pictet, classed it with the manati and herbivorous cetaceans. Prof. Kaup considered it a pachyderm, intermediate between the mastodon and the tapir. In 1836 the discovery of a cranium by Dr. Klipstein seemed to settle the position of the dinotherium among the pachyderms; in 1837, this head was exhibited at Paris, where several casts were taken. It is nearly 4 feet long, 2 feet broad, and $1\frac{1}{2}$ feet high, its summit divided into 2 parts by a well-marked ridge, and its occipital surface wide and oblique, with a globular occipital condyle; the nasal aperture is very large, as in the elephant and mastodon, with the large suborbital foramina indicating the possession of a proboscis. The lower jaw is remarkable for its curve downward, and its 2 tusks pointing in the same direction, forming a hook about 3 feet in length and describing $\frac{1}{4}$ of a circle. The primary teeth appear to have been 12, 3 on each side of each jaw, and the permanent teeth 20, 5 on each side of each jaw; the front 2 on each side, making 8, are premolars, and resemble those of the tapir; the upper 12 teeth, the true molars, resemble those of the mastodon in their transverse ridges, but differ from them in their square form; they are developed vertically, as in man and most mammals, while those of the elephant family are developed horizontally. If the bones of the trunk and extremities attributed to this animal really belong to it, which is exceedingly doubtful, it would have a length of 18 feet and a height of 14, 2 feet longer and higher than the largest mastodon discovered. The shoulder blade is de-

scribed as like that of the mole, indicating that the fore feet were adapted for digging in the earth. It is not very easy to decide whether this animal was most terrestrial or aquatic in its habits. Pictet, in his *Traité de paléontologie* (1853, vol. i. p. 371), expresses the opinion that it was a herbivorous cetacean, from the long and hanging tusks which a terrestrial animal could hardly use, the depression of the occipital bone (this being nearly vertical in the pachyderms), the wide opening of the nasal fossæ, the form of the intermaxillaries and of the ocular and temporal fossæ; he would make it an aquatic animal, though coming nearer the proboscidians than does the existing manati; living near the mouths of rivers, it fed upon the fleshy portions of plants which it rooted up with its tusks. On the contrary, Owen, Kaup, and De Blainville consider it a terrestrial proboscidian, intermediate between the mastodon and tapir. These two opinions are really not very different from each other, since it is now generally agreed that the manati and dugong, or the herbivorous cetacea, must be removed from the order of cetacea and placed among the pachydermata, of which last they are the embryonic type. (For details on this subject see the "Proceedings of the American Association for the Advancement of Science," 3d meeting, in Charleston, S. C., March, 1850, p. 42.) Considering then the dinotherium to be a true pachyderm, its favorite element, air or water, may be a matter of question. It has no incisor teeth; its inferior tusks seem admirably adapted to drawing its heavy body out of water upon the banks of rivers; they would also serve for rooting up aquatic plants, assisted by the mole-shaped fore feet. Dr. Buckland suggests that the tusks served to anchor the animal to the shore, while it slept in the water. It cannot be far from the truth to call it an aquatic pachyderm, similar in habits to the hippopotamus, living in lakes and marshes. The best known species (*D. giganteum*, Kaup) was found at Eppelsheim, a few leagues south of Mentz, in clayey marl about 18 feet below the surface, in connection with bones of other pachyderms; their remains have been found only in the miocene strata. Other smaller species are described, as the *D. Cuvieri* (Kaup), *D. minutum* (H. de Meyer), and *D. proavum* (Eichwald), in Europe; *D. Indicum* (Cautley and Falconer), from the Sivalik hills; and the *D. australe* (Owen), of Australia.

DINWIDDIE, a S. E. county of Va., bounded N. by the Appomattox river, and S. W. by the Nottoway; area, 540 sq. m.; pop. in 1850, 25,118, of whom 10,880 were slaves. It has a rolling surface and a soil well adapted to grain and tobacco. In 1850 it produced 304,556 bushels of Indian corn, 60,275 of wheat, and 1,782,521 lbs. of tobacco. There were 3 cotton factories, 25 flour and grist mills, 3 newspaper offices, 36 churches, and 1,092 pupils attending schools and academies. Value of real estate in 1856, $2,537,279. It is intersected by the railroad from Richmond to Weldon, N. C. The county was organized in 1752, and named in honor of Gov. Dinwiddie. Capital, Dinwiddie Court House.

DINWIDDIE, Robert, lieutenant-governor of Virginia, born in Scotland about 1690, died in England, Aug. 1, 1770. While acting as clerk to a collector of the customs in one of the British West India islands, he was instrumental in detecting and exposing the frauds practised by his principal, and as a reward for his services he was soon after appointed lieutenant-governor of Virginia. He arrived in the colony in 1752, and remained until Jan. 1758, when he returned to England. His administration covered a stirring period in colonial history, and he proved himself a zealous and active officer, although totally ignorant of military affairs. He had, however, the sagacity to discern the capacity of Washington, whom in 1753 he appointed adjutant-general of one of the 4 military districts of Virginia, and sent as a commissioner to expostulate with the French commander on the Ohio for his aggressions upon British territory. At the outbreak of hostilities with the French and Indians, he called upon the governors of the other provinces to make common cause against them, and convened the house of burgesses of Virginia to devise measures for the public security. Entertaining peculiar notions of the royal prerogative and of his own importance, he was highly incensed at the tardiness of the latter body in voting money for the public defence, and at their refusal to put it under his absolute disposal. In 1754 he suggested to the British board of trade the propriety of taxing the colonies for the purpose of raising funds to carry on the war, and in the succeeding year he was one of the 5 colonial governors who at an interview with Gen. Braddock, at Alexandria, Va., memorialized the ministry to the same effect. After the defeat of Braddock, he continued to busy himself with the military operations on the frontiers, displaying great incapacity, and wearying Washington, then in command of the colonial troops, by frequent exhibitions of ill temper, folly, or caprice. He enjoyed little popularity in Virginia, where his arrogance brought him into collision with the legislature, while his avarice led him to exact illegal or obsolete fees, such as a pistole for every patent granted, a perquisite which no governor had claimed for many years. At the time of his departure he was also charged with having appropriated to his own use the sum of £20,000 which had been sent by the British government as a compensation to Virginia for moneys expended by her beyond her proportion, and which he never satisfactorily accounted for.

DIOCESE (Gr. διοικησις, administration), an ecclesiastical division of a state, the circuit of a bishop's jurisdiction. In Roman antiquity, the term *diocæsis* designated one of the 4 prefectures or civil divisions into which the empire was partitioned by Constantine the Great; and at a later period the empire became divided into 14 dioceses or prefectures, which comprehended 120 provinces. The civil constitution was fol-

lowed in the government of the church, and the diocese was originally a great ecclesiastical district, embracing several bishoprics, and under the primacy of the bishop of the principal city, who bore the title either of metropolitan, archbishop, exarch, or patriarch. The diocese is now in the Roman Catholic church the district subject in ecclesiastical affairs to the authority of an archbishop or bishop; in the episcopal Protestant churches, the district ruled by a bishop; and in the Evangelical church of Germany, the combination of parishes under the care of a superintendent. In England, every diocese is divided into archdeaconries; each archdeaconry at least nominally into rural deaneries; and every deanery into parishes.

DIOCLETIAN, Valerius, a Roman emperor, born at Doclea or Dioclea, a small village near Salona in Dalmatia, A. D. 245, died in Salona in 313. He was of obscure parentage, but by his abilities rose rapidly in the army. On the death of Numerian in 284, he was named emperor by the troops, then returning from the Persian expedition which they had commenced under Carus, but had abandoned on the sudden death of the latter. They retreated under his son Numerian, who died on the march, not improbably at the instigation, if not by the hand, of Arrius Aper, his father-in-law. The death of Numerian was concealed for a time, but the soldiers, having discovered it, chose Diocletian emperor, and the latter immediately plunged his sword into the bosom of Aper, thus avenging the death of Numerian, and at the same time happily fulfilling an old prophecy which he had received from a druidess in Gaul, to the effect that he would reign when he should have slain the wild boar (Lat. *aper*). But Diocletian was not without a rival; Carinus, brother of Numerian, was recognized as emperor in Europe. The armies of the hostile sovereigns met near the small city of Margus, not far from the Danube in Mœsia, where victory declared itself in favor of the veteran legions of the West; but Carinus, eagerly following the flying enemy, was killed by one of his own officers, and his army readily acknowledged Diocletian as his successor. The latter soon, however, thought it necessary to associate with himself a colleague in the supreme dominion, and fixed his choice on Maximian, his old companion in arms, a rough barbarian, whom he invested with the imperial dignity in 286, and in whom he found a useful assistant and a constant friend. The Roman empire was beset with enemies and torn by factions. The peasants of Gaul rose in arms; Mauritania was in rebellion; Egypt was disturbed by external enemies and internal convulsions; while all along the frontier, from the Euphrates to the Rhine, the barbarians were threatening to destroy the empire by the invasions of their countless hordes. Maximian subdued the Gallic peasants, Bagaudæ, as they were styled, but Diocletian was compelled to strengthen the empire by raising two more Roman soldiers to the purple, Galerius, son of a Dacian shepherd, and Constantius, surnamed Chlorus, son of a noble Mœsian, and father of Constantine the Great. These two princes received the title of Cæsars, and having repudiated their wives, Galerius married the daughter of Diocletian, and Constantius the stepdaughter of Maximian. Britain, Gaul, and Spain were assigned to Constantius; Galerius received the Illyrian and Danubian provinces; Italy, Africa, with Sicily, and the islands of the Tyrrhenian sea, were held by Maximian; while Diocletian, the head of all, retained under his own dominion Thrace, Egypt, and the provinces of Asia. By this arrangement, on the death of either of the Augusti, as Maximian and Diocletian were styled, the Cæsar who had been associated with him was to be his successor, and another Cæsar was to be appointed. These four princes, it was thought, would hold one another in check, so that no one of them would be able to attain to uncontrolled power. The plan was for a time successful. Maximian subdued the rebellious provinces of western Africa; Diocletian reduced and secured Egypt; Galerius not only, under the superintendence of his father-in-law, compelled the haughty Persians to make a treaty which secured the frontiers of that part of the empire for 40 years, but also vigilantly guarded the Danubian frontier; while Constantius invaded Britain, which for several years had been detached from the rest of the empire under the rule of the usurper Carausius, and restored that island to the control of the Roman emperors. But the evils of this system of division, though not immediate, were certain; and the permanent splitting of the empire into 2 distinct governments was its legitimate result. After a prosperous reign of about 21 years, Diocletian, moved by his infirm health, or, as is said, by the persuasions or menaces of his son-in-law Galerius, voluntarily resigned the throne (305), and retired to Salona in his native country of Dalmatia, where he passed the remaining 8 years of his life in retirement. Maximian, according to a previous agreement, abdicated at the same time, but was not so contented in a private station as Diocletian, and, a few years later, wrote to his former colleague, proposing to him to resume the reins of government. The reply of Diocletian has become celebrated. "Would you could see," he says, "the cabbages planted by my hand at Salona; you would then never think of urging such an attempt." Diocletian introduced great changes in the Roman state. He struck a severe blow at the waning influence of the senate by the removal of his court from Rome to Nicomedia, reduced the numbers and the importance of the prætorian guards, divided the provinces so as to lessen the power of the provincial governors, and increased the dignity and ceremony with which the emperor was surrounded. He is deservedly censured for persecuting the Christians; but it is supposed, as he himself seemed to be favorably disposed to them during the greater part of his reign, and as he was much under the influence of Galerius, a superstitious savage,

that he may have been induced to pursue this course by the artful persuasions of the latter. It must be remembered also, that the greater part of these persecutions took place after. Diocletian had resigned his authority.

DIODATI, Domenico, an Italian archæologist and theologian, born in Naples in 1736, died there in 1801. He wrote several works on ecclesiastical history, and one on the coins of the Italian states; but the work by which he became widely known, and which will remain one of the most curious monuments of ingenious speculation, is entitled *De Christo Græce loquente Exercitatio, qua ostenditur Græcam sive Hellenisticam Linguam cum Judæis omnibus, tum ipsi adeo Christo Domino et Apostolis, nativam ac vernaculam fuisse* (Naples, 1767). The strange theory that Greek was the native language of the Jewish people in the time of Christ, not only familiar to the cultivated classes, but the dialect of the common people, is advocated in this work with remarkable subtlety, nice comparison of passages, and a great variety of proofs, both external and internal. The Della Cruscan academy made him at once one of its associate members, and the delighted empress of Russia, patron of the Greek church, sent a gold medal to the man who had done such service to the language of the sacred records.

DIODATI, Giovanni, a Swiss theologian, born in Geneva in 1576, died in 1649. His parents, refugees from persecution, had found that home in Geneva which was denied them in their native city of Lucca. At 21 years he became, on the nomination of Beza, a professor of Hebrew. In 1608 he was made parish minister in the Reformed church, and in 1609 became professor of theology. On a visit to Venice he had several interviews with Fulgentius and Fra Paolo Sarpi, the famous historian of the council of Trent, at the time that they were resisting the secular influence of the papacy. In 1618–'19 Diodati, already noted as a preacher both in France and Switzerland, attended the synod of Dort, where, with Theodore Tronchin, he represented the church of Geneva, and was one of the 6 ministers appointed to draw up the articles of faith. In this synod he showed himself a zealous Calvinist, and offended many by his bitterness against the Remonstrant party. In 1633 he drew up, along with Le Clerc, a preface to the confession of faith of Cyril Lucar, patriarch of the Greek church at Constantinople. This remarkable and unfortunate prelate had been for many years the associate, correspondent, and admirer of the leading reformers, and was indefatigable in his efforts to engraft Lutheran and even Calvinistic ideas upon the creed of the eastern church. In 1645 Diodati relinquished his office as professor, and passed the remaining years of his life in retirement. He was considered by many to be the most learned biblical scholar of his day. Among his works are an Italian version of the Bible (1607); a free Italian translation of the New Testament (1608); *Mortis Meditatio Theologica* (Geneva, 1619); the "Papal Fiction of Purgatory" (1619); a French translation of Job, Ecclesiastes, and Canticles (1638), of the Psalms (1640), and of the whole Hebrew Bible (1644); *Glossæ in Sancta Biblia* (fol. Geneva, 1641), in Italian; and a great number of other theological and controversial writings.

DIODORUS, commonly called Diodorus Siculus, a Sicilian historian of the time of Cæsar and Augustus, was born in Agyrium, but the precise epochs both of his birth and of his death are unknown. He spent 30 years in composing a universal history, and in the preparation of this work he traversed a large portion of Europe and Asia. The first 6 books treated of the times anterior to the Trojan war; the 11 following extended to the death of Alexander the Great; while in the 26 remaining, the history was brought down to the time of Julius Cæsar. Of this extensive work, which was styled Βιβλιοθηκη, or Βιβλιοθηκη Ἱστορικη (library, or historical library), we have now only 15 books entire, and a few fragments of the rest. The first 5 books, containing the ancient history of the eastern nations, the Ethiopians, Egyptians, and Greeks, and the 10 from the 11th to the 20th inclusive, comprising the history of events from the second Persian war, 480 B. C., down to 302 B. C., remain entire. Many fragments of the other books are preserved in the works of Photius, and in the *Eclogæ*, or selections, made by order of the emperor Constantine Porphyrogenitus. The Bibliotheca is the only work of Diodorus of which we have any knowledge, the collection of letters attributed to him being probably a forgery. It is written in the style of annals, and the events are narrated in a confused and discordant manner; but the work is valuable as giving us, if not always information of facts, at least of the opinions of men, with regard to a period in history concerning which our information is so exceedingly meagre, that the slightest addition to it is of great value. The first 5 books are especially prized on this account. Most of the events treated in the other ten are better told by Thucydides and Xenophon, who are silent, however, upon the Carthaginian wars in Sicily related by Diodorus. The best modern editions of his works are those of L. Dindorf (6 vols. 8vo., Leipsic, 1828), and Müller (Paris, 1842–'4). That portion of his history which relates to the successors of Alexander was translated into English by Thomas Stocker (4to., London, 1569). His whole work was translated by Thomas Cogan (fol., London, 1653), and by G. Booth (fol., London, 1700 or 1721; republished, 2 vols. royal 8vo., London, 1814).

DIOGENES, a Cynic philosopher, born in Sinope, in Pontus, Asia Minor, about 412, died near Corinth, 323 B. C. His father was a banker, and was condemned for having adulterated the coinage; and whether his son was involved in the same condemnation or not, it is certain that the latter left his native country and took refuge in Athens. Here he became a disciple of Antisthenes, the founder of the Cynic school of

philosophy. The latter was at first unwilling to receive him, driving him rudely from his door, and threatening him with his staff. "Strike," said Diogenes; "you cannot find a stick so hard as to compel me to go away, while you speak that which I wish to hear." Diogenes soon gained a reputation superior to that of his master for rough and caustic wit. The anecdotes related of him, whether they are all true or not, will help us to form a judgment of the character of the man. One day at Athens the citizens saw him with a lantern in his hand, although it was broad day, apparently searching for something. On being asked what he was seeking, he replied: "A man." He had found children, he said, in Sparta, and women in Athens, but men he had never seen. At another time he called out: "Approach, all men;" and when the citizens drew near, beat them back with a stick, saying: "I called for men, but ye are excrements." He used to carry a small drinking vessel with him, but broke it on seeing a boy drink from the hollow of his hand. He slept either under the portico of some building, or in a tub, which was his ordinary dwelling, and which he carried about with him. The truth of this popular statement, however, has been much disputed both by ancient and modern critics. He taught in the streets and public places, speaking with the utmost plainness, often with rudeness, and was altogether insensible to reproaches and insults. His wit was ready and severe. Plato defined man as a two-legged animal without feathers; whereupon Diogenes, having stripped a fowl of its plumage, threw it among the scholars of the great academician, bidding them behold one of Plato's men. Being asked which is the most dangerous animal, he answered: "Of wild animals, the slanderer; of tame, the flatterer." On a voyage to the island of Ægina, he was captured by pirates, and afterward sold as a slave. While in the market place, waiting for a purchaser, being asked what he could do, he answered that he knew how to govern men, and bade the crier to ask: "Who wants to buy a master?" He was purchased by Xeniades, a Corinthian, who carried him home, and afterward set him at liberty, intrusting to him the education of his children. The rest of his days Diogenes divided between Athens and Corinth, and it was at the latter place that his celebrated but apocryphal interview with Alexander the Great is said to have taken place. The king of Macedon, surprised at the indifference with which he was regarded by the ragged philosopher, who was comfortably basking in the sun before his tub, said to him: "I am Alexander." "And I," was the reply, "am Diogenes." Alexander desired him to ask a favor; but all that the Cynic wished was, that Alexander would not stand between him and the sun. Struck with this extraordinary insensibility to the usual weaknesses of humanity, the Macedonian remarked: "Were I not Alexander, I would be Diogenes." He loved to display his contempt of the common courtesies of life. Plato was giving a magnificent dinner to some friends, and Diogenes entered unbidden, and, stamping with his dirty feet on the carpets, exclaimed: "Thus I trample on the pride of Plato." "But with greater pride, O Diogenes," replied Plato. Surly, independent, constantly grumbling at the vices of mankind, a voluntary outcast among his fellow-men, he lived on to a great age, and died in his 90th year. According to Diogenes Laërtius, he wrote several works, but nothing has come down to us with the exception of some sayings preserved by the above-mentioned author, and it is even doubted by some whether he ever wrote any thing. He did not teach by lectures, but uttered his philosophy in short, pithy sentences, as occasion offered.

DIOGENES OF APOLLONIA, a Greek philosopher, born at Apollonia in Crete, flourished in the 5th century B. C. Very little is known of his life. He was at Athens probably about 460, and became involved in some trouble there, perhaps in consequence of his philosophical speculations. These latter were developed in his work Περι Φυσεως, "On Nature," which was still extant in the 6th century, but of which we have at present only a few fragments, preserved in the works of Aristotle, Diogenes Laërtius, and Simplicius. His great object was to find the first principle of the world, out of which all things were evolved. Like his master Anaximenes, he came to the conclusion that this great first principle was air. Air of various degrees of condensation formed the atmosphere, fire, water, and earth, and out of these every thing else was evolved. But he went beyond his master in endowing this subtle first principle with a certain intelligence, presiding over the arrangement of the universe, the marks of which are visible in the order and beauty of creation. The brutes, he says, are inferior to man, because they inhale an air less pure, holding their heads near the ground. The world, too, he supposed to be animated, and he imagined the stars to be its organs of respiration. The fragments of Diogenes which have come down to us were published by Panzerbeiter (Leipsic, 1830).

DIOGENES LAËRTIUS, an ancient historian of philosophy, who probably lived toward the end of the 2d century, though the dates of his birth and of his death are alike unknown, and his life has been placed as early as the time of Augustus, and as late as that of Constantine the Great. He is supposed to have been born in Laërte, in Cilicia, but of his life we know absolutely nothing. He wrote a history of philosophy in Greek, divided into 10 books, and giving an account of the philosophers, anecdotes of their lives, and illustrations of their teachings. He considers Grecian philosophy not to have been derived from without, but to have been indigenous, and he divides it into two schools: the Ionic, commencing with Anaximander and ending with Clitomachus, Chrysippus, and Theophrastus, and of which the Socratic school forms a part; and the Italian, whose founder is

Pythagoras, and whose last master is Epicurus, and which includes in its comprehensive embrace Heraclitus, the Eleatics, and the Sceptics. The account of these two schools comprises the whole of the work, with the exception of the first book, which contains the history of the 7 wise men of Greece, whom he considers rather as precursors to Grecian philosophy than as properly belonging to it. The work of Diogenes is valuable for information which we could obtain from no other source; but it is ill-digested, written without critical judgment, and often inaccurate. Diogenes is supposed to have written some other works, among which was a volume of epigrams, but, judging from the specimens of his talent in this sort of composition which are found interwoven with his philosophical history, we have no cause to regret their loss. A good edition of his history is that of H. G. Hübner (2 vols. 8vo., Leipsic, 1828–'31). A translation into English was published (2 vols. 8vo., London, 1688). There is another translation by C. D. Yonge in Bohn's "Classical Library."

DIOMEDES. I. One of the most famous of the Grecian heroes at the siege of Troy, and, after Achilles, considered the bravest of all the Greeks. According to Homer, his father Tydeus was one of the leaders in the memorable expedition of the seven against Thebes, and was killed before the walls of that city, while Diomedes was still a boy. The latter, however, having arrived at the age of manhood, joined the second expedition against Thebes, and avenged his father's death. With 80 ships he sailed in the great Grecian armament to the siege of Troy, where, beside a multitude of victories over heroes of less note, he engaged and put to flight Hector and Æneas, and also wounded both Venus and Mars, the divine defenders of the city. He was also famed for his wisdom in council, and when Agamemnon, dispirited by adversity, proposed to abandon the siege, Diomedes declared that he with his friend Sthenelus would remain, at all events, until Troy should fall. According to later legends, he carried off with Ulysses the palladium from Troy. Of his history after the fall of Troy Homer gives us no account, but later writers tell us that, having returned to Argos and found his wife unfaithful, he abandoned his native country, and sought a home elsewhere. Traditions differ with regard to his after life. According to some accounts, he went to Ætolia, and afterward returned and gained possession of Argos. Another relates that, in attempting to return to Argos, he was driven by a storm upon the coast of Italy, where he was kindly received by King Daunus, whom he assisted in a war against a neighboring tribe, and whose daughter Euippe he received in marriage. II. A king of the Bistones in Thrace, son of Mars and Cyrene, celebrated for his mares, which he fed upon human flesh. To obtain possession of these mares was one of the 12 labors of Hercules. The hero slew Diomedes, whose body he gave to the mares, and they, though previously savage, became tame after eating their master's flesh.

DION OF SYRACUSE, a disciple of Plato, celebrated for having overthrown the power of Dionysius the Younger, tyrant of that city, born toward the close of the 5th century B. C., killed in 353. Under Dionysius the Elder, who was married to his sister Aristomache, he enjoyed the favor of the court, and amassed great wealth; but when the younger Dionysius succeeded to the throne, Dion, whose austere manners were a constant rebuke of the royal debaucheries, fell into disgrace, and at last was banished from Sicily. He found refuge and a friendly reception in Greece, where he lived for a while in affluence, his income being still allowed to reach him. Soon, however, this was cut off, and to complete his disgrace, his wife Arete was compelled to marry another man. Dion knew that the Syracusans hated their tyrannical ruler, and he now resolved to avenge himself and his country at the same time. Having assembled a body of about 800 troops, he sailed from Zacynthus, landed in Sicily, and easily obtained possession of Syracuse in the absence of Dionysius. The troops of the tyrant, however, still held the citadel on the neighboring island of Ortygia, whence they made a sally soon after the arrival of Dion, and were repulsed only after a fierce combat, during which Dion himself displayed great courage. He was at first received by the citizens with enthusiasm, and on his entry into the city he proclaimed liberty to Syracuse. But irritated by his harsh manners, suspecting his designs, and incited by the demagogue Heraclides, the people afterward expelled him and his troops. The Syracusans soon had reason to repent of their conduct, for the soldiers of Dionysius, aware of their dissensions, made a sally, regained part of the city, set fire to the houses, and began a fearful massacre. The banished philosopher was entreated to return, and marching immediately, he succeeded after a hard contest in obtaining full control of Syracuse. It is not improbable that he intended to establish an oligarchical government, though he has been suspected of an intention to retain the supreme power in his own hands. He caused his opponent Heraclides to be put to death. This act greatly injured his popularity, already damaged by his repellant and austere manners; a conspiracy was formed against him, and he was not long after assassinated.

DION CASSIUS COCCEIANUS, an ancient historian of Rome, born in Nice in Bithynia about A. D. 155, went to Rome about 180, where he was made senator. He was afterward appointed to many offices of trust by different emperors, and was twice raised to the consulship. Having become odious to the prætorian guards, because, it is said, of the severe discipline which he had imposed, he obtained permission from the emperor Alexander Severus, in 229, to retire to his native city of Nice, where he spent the remainder of his days. His great work was a history of Rome (Ῥωμαϊκὴ

Ἱστορια), written in Greek, divided into 80 books, and containing an account of the rise and progress of the state from the landing of Æneas in Italy until A. D. 229, giving only a slight sketch of events down to the time of Julius Cæsar, but dwelling with more minuteness on the history of later times, and especially on that of the author's own age. Of this work, which is written with clearness, diligence, and general accuracy, but in a faulty style, 20 books (from the 36th to the 54th) remain entire. Fragments of the first 35 have been collected, and there are abridgments of the last 25 and of the entire work. One of the best editions of Dion Cassius is that of Sturz (9 vols. 8vo., Leipsic, 1824–'25–'43). An English translation of Xiphilin's abridgment was published in London (2 vols. 8vo., 1704).

DION CHRYSOSTOMUS (*i. e.*, Dion the golden-mouthed), a Greek rhetorician, born in Prusa (now Broussa), in Bithynia, about the middle of the 1st century, died in Rome about A. D. 117. In the practice of his art at Rome, he incurred the hostility of the emperor Domitian, and in consequence of a decree of the senate he was obliged to flee from Italy. In the habit of a beggar, with Plato's "Phædon" and Demosthenes's "Oration on the Embassy" in his pocket, he wandered through Thrace and the countries bordering on the lower Danube, and on receiving intelligence of the death of Domitian (96) used his influence and his oratorical powers with the army stationed on that frontier in favor of Nerva. It is probable that he returned to Rome on the accession of this emperor, from whom as well as from his successor Trajan he received tokens of marked kindness. About A. D. 100 he returned to Prusa, but remained but a short time, and then went back to Rome. He was an essayist rather than an orator, and his writings are distinguished for elegance of style. Of his orations 80 have come down to us. There is a very good critical edition of them by Reiske (2 vols. 8vo., Leipsic, 1784).

DIONÆA (*D. muscipula*, Ellis), Venus's fly trap, a plant inhabiting the savannas around Wilmington, N. C., and extending N. as far as Newbern, N. C. Elliott, on the authority of Gen. Pinckney, says that it grows along the lower branches of the Santee in South Carolina. Mr. Audubon informed Mr. Curtis, with the plant before him, that he had seen it in Florida of enormous size. Specific characters: calyx herbaceous; petals 5, hypogynous on the margin of the dilated receptacle, alternate with the sepals; stamens 10 to 20, hypogynous within the petals, shorter than they; filaments filiform; anthers oblong, of 2 parallel cells without connection; pollen of pretty large grains, composed of 4 united; ovary depressed, ovoid, one-celled, 5 lobes, the lobes alternate with the petals; style columnar, pretty large, undivided; stigmas 5, corresponding with the lobes of the ovary; ovules indefinite, erect, sessile on and uniformly covering the nearly flat basilar placenta, which occupies the whole bottom of the cell; herb acaulescent, smooth, with fibrous roots, and a cluster of spreading yellowish green leaves, traversed by a strong midrib bearing on its apex an orbicular herbaceo-coriaceous lamina, emarginate at both ends, fringed with a row of bristles, the 2 sides conduplicate, the upper surface dotted with minute glands, in which the sensitiveness of the leaf chiefly resides. The lobes or sides of the lamina are folded at night, but spread during the day, when if the glands be roughly touched, or an insect alights upon them, the sides suddenly close on the intruder. After remaining contracted for some time, the trap again opens, ready to enclose a new intruder; but by repeated irritation at short intervals its movements become languid, and its sensibility is for the time entirely exhausted. The best popular description of this singular plant is given by Curtis in his enumeration of plants growing spontaneously around Wilmington, N. C., communicated to the Boston society of natural history in 1834, and published in the proceedings of that society. "The leaf," remarks Mr. Curtis, "which is the only curious part, springs from the root, spreading upon the ground or at a little elevation above it. It is composed of a petiole or stem with broad margins like the leaf of the orange tree, 2 to 4 inches long, which at the end suddenly expands into a thick and somewhat rigid leaf, the 2 sides of which are semi-circular, about $\frac{2}{3}$ of an inch across, and fringed around the edge with somewhat rigid ciliæ or long hairs like eyelashes. It is very aptly compared to 2 upper eyelids joined at their bases. Each side of the leaf is a little concave on the inner side, where are placed 3 delicate hair-like organs in such an order that an insect can hardly traverse it without interfering with one of them, when the 2 sides suddenly collapse and enclose the prey with a force surpassing an insect's efforts to escape. The fringe or hairs of the opposite sides of the leaf interlace, like the fingers of the 2 hands clasped together. The sensitiveness resides only in these hair-like processes on the inside, as the leaf may be touched or pressed in any other part without sensible effects. The little prisoner is not crushed and suddenly destroyed, as is sometimes supposed, for I have often liberated captive flies or spiders, which sped away as fast as fear or joy could hasten them. At other times I have found them enveloped in a fluid of a mucilaginous consistence, which seems to act as a solvent, the insects being more or less consumed by it. This circumstance has suggested the possibility of their being made subservient to the nourishment of the plant, through an apparatus of absorbent vessels in the leaves." The discovery of this plant has led naturalists to make experiments upon plants with the view of ascertaining the possibility of their appropriating animal matter to their own nourishment, with such success as to lead to the belief that the form and organization of the *dionæa muscipula* is really intended to entrap its insect prey, for the purpose of furnishing a kind of food to the plant, which, although not essential to its

existence, performs an important part in its economy.

DIONYSIUS OF ALEXANDRIA, saint and bishop of the church, born in Alexandria, in Egypt, in the last years of the 2d century, died in that city, A. D. 265. He was of a noble and wealthy family. His parents were pagans; but in the course of his early philosophical studies his attention was turned to the Christian sacred writings, especially the epistles of Paul, and he became a convert. He left the heathen schools, became a pupil of Origen, was ordained priest, and in 232 was chosen to succeed Heraclas as chief of the Alexandrian school of theology. In 248 he was raised to the office of bishop, made vacant by the death of Heraclas. Shortly after this, violent persecutions broke out against the Christians. The populace of Alexandria had been stirred up against them by a certain heathen false prophet, and the edict of Decius, which reached that city A. D. 250, put arms in the hands of the enraged enemies of the Christian name. Dionysius, who had taken an active part in preparing the Christians for the coming trial, was marked for a victim, was arrested, sent to be put to death, rescued by a band of peasants, and he remained concealed more than a year in the Libyan desert, sending continual messages meanwhile to his brethren in the city. In the persecution under Valerian in the year 257, Dionysius was again exiled from his see. After his restoration (A. D. 260), he was more than once called to mediate on occasions of public strife.—The writings of Dionysius were numerous, but most of them have been lost. They were mainly controversial. In opposition to Nepos, bishop of Arsinoë, who preached the millennial earthly reign of the Saviour at his second coming, Dionysius wrote 2 books refuting the theory. In opposition to Sabellius, who denied the distinct personality of the members of the Trinity, he wrote several books and epistles, caused the heresy to be condemned by a council, and insisted upon the distinction between the Son and the Father so strongly, that it brought upon him the charge of denying the divinity of Christ, against which he defended himself. According to Basil, he also defended the doctrine of the divinity of the Holy Spirit. In opposition to Paul of Samosata, Dionysius maintained the consubstantial nature of the Son and the Father. The fragments of his writings were collected by Simon de Magistris (Rome, 1796) in a folio, and are also contained in the 3d volume of the *Bibliotheca Patrum*.

DIONYSIUS THE AREOPAGITE, an Athenian, styled by Suidas a master of Greek erudition, and who was one of the council of the Areopagus when St. Paul preached to the Athenians. He is said to have studied first at Athens, and afterward at Heliopolis, in Egypt. There is a legend that when he observed in Egypt the darkening of the sun which occurred during the crucifixion of Jesus Christ, he exclaimed: "Either God himself is suffering, or is sympathizing with some one who is suffering." He was converted by the preaching of Paul, about A. D. 50; is mentioned in the Acts of the Apostles (xvii. 34), and was the first bishop of Athens, having been appointed to that office, it is said, by St. Paul himself. It is probable that he suffered death by martyrdom, but in what year is not known. It is not certain that Dionysius the Areopagite ever wrote any thing, but his name has been given to several theological treatises, imbued with the mystical doctrines of the Alexandrian Platonism. These works, 4 in number, are first mentioned in the 6th century, contain allusions to facts and quotations from authors subsequent to the apostolic age, and were probably written by some Neo-Platonic Christian of the 4th or 5th century. They exercised a great influence upon the development of Christian doctrine in the middle ages, were translated into Latin by Scotus Erigena, and gave the first impulse to that theology which the combined efforts of mystics and schoolmen maintained for centuries. The fact that this Dionysius became confounded with the patron saint of France perhaps invested these writings with an importance which they would not have acquired from their intrinsic merits.

DIONYSIUS THE ELDER, tyrant of Syracuse, son of Hermocrates, born in 430 B. C., died in 367. While a clerk in a public office, he came forward in the popular assembly as the accuser of the unsuccessful Syracusan commanders, who had suffered Agrigentum and other foremost cities of Sicily to be taken by the Carthaginians. He displayed so much vigor of character, and the condition of Syracuse was so critical, that even men like the historian Philistus saw in him the only safety for the country. He succeeded in obtaining a decree for deposing the obnoxious generals, and for appointing others in their stead, and was himself elected among the new officers. He then brought false accusations against his associates, and the people determined to depose them, and appointed him, 405 B. C., sole general, with full powers, and allowed him to protect himself by a body guard. He now began those measures which made him proverbial in antiquity as a tyrant; and concerning himself no longer for the deliverance of Sicily from the Carthaginians, aimed only to subdue his native city. He induced the Syracusans to double the pay of the soldiers, appointed officers who were in his own interest, and, by marrying the daughter of the patriot Hermocrates, secured the support of the partisans of that leader. He was received as commander-in-chief of the Sicilians, who had concentrated their forces at Gela, and he offered battle to the Carthaginians in so unskilful a manner as to make it probable that he did not regret the defeat in which it resulted. He withdrew the inhabitants of Gela and Camarina to Leontini, and left the whole of the western coast to the Carthaginians. This reverse gave a shock to his popularity, and enabled his enemies to raise a revolt in Syracuse, where he was now looked

upon as a manifest traitor. They gained possession of the city, but their plans being disconcerted by the sudden return of Dionysius, they were driven out, though not until his wife had fallen a victim to their cruelty. The Carthaginian generals now besieged Syracuse, but the plague having broken out in their camp, they were satisfied with the immense advantages offered them by Dionysius without storming the place. He was recognized as ruler of Syracuse, and of a district of land around the city, but was to resign all claim to dominion over the island. He availed himself of the peace to establish his tyranny on firmer foundations; and having fortified the isle of Ortygia, and excluded from it all but his immediate dependants, he built upon it a citadel which might serve as an impregnable asylum. The Carthaginians lost the advantages of the peace through negligence. Syracuse had in 6 years recovered her strength, and Dionysius undertook the recapture of the cities which he had surrendered. The immense preparations which he made form an epoch in ancient military history. His machinists invented engines for throwing missiles, and especially devised the catapult, which may be termed the artillery of the ancients. He also constructed ships having 4 or 5 banks of rowers, instead of the old triremes. He gained at first great success in the war, and conquered Motya, the ancient seat of the Carthaginian dominion. His fleet, however, was defeated by that of the Carthaginians, which then ravaged the northern coast of the island, overpowered Messana and Catana, and laid siege to Syracuse. But the plague, or some malady resembling it, breaking out in the camp of the enemy, proved the safety of the city. Nearly the whole Carthaginian army was lost by the fearful pestilence, and the remainder purchased from Dionysius the privilege of a free departure. In the treaty which followed, the restrictions which had been imposed by the last treaty upon the government of Syracuse were removed. Dionysius carried on also a 3d and 4th war with Carthage, the results of which seem to have been only to reëstablish the terms of the former peace. The intervals between these wars were harassed by the revolts of his subjects, which he avenged with cruelties; and the frequent attempts upon his life made him suspicious. He dared not trust even his relatives, and his body guard was formed of foreigners. No one was admitted to his presence till after being searched, and often an innocent pleasantry of conversation was punished as a menace. His palace was surrounded by a ditch, which was crossed by a drawbridge, and when he harangued the people it was from the top of a lofty tower. He built the terrible prison of the *lautumiæ*, cut deep into the solid rock, and another of his prisons was so arranged that every word spoken within it was reëchoed into his chamber; and he is said to have passed entire days listening to the complaints of his victims. Tradition, in making of Dionysius the type of cruelty, has doubtless transmitted some unauthenticated stories concerning him; but even a legend like that of Damocles and the sword shows his mind always alarmed, and his hand always raised to defend his imperilled life. Dionysius was long engaged in ambitious projects against the Greek cities of southern Italy. He formed an alliance with the Locrians, and after suffering some reverses besieged and conquered Rhegium. Italy was now open to him, and he sought by establishing colonies upon the Adriatic to secure for himself a way into Greece. Already his name was known in the Peloponnesus, where he had contracted an alliance with the Lacedæmonians. He was now the recognized master of southern Italy, interfered in the affairs of the Illyrians, sent an army into Epirus, and received an offer of friendship from the Gauls, who had burned Rome. His settlements upon the Adriatic increased his wealth and strengthened his power, but they were his last great undertakings, and henceforth he disappears from history. He was so detested in Greece, that the auxiliaries which he sent to his allies the Spartans only drew upon the latter the hatred of all their countrymen. His reign lasted 38 years, and became milder toward its latter part. He left an immense military force and a powerful empire, and though he had governed as a tyrant, the old republican forms remained. Niebuhr affirms that a republic was as great an impossibility at Syracuse under Dionysius as at Rome under Cæsar, and blames him therefore for not having given to his countrymen institutions suited to them, instead of allowing the old democratic forms to exist in all their impotent absurdity, merely for the purpose of enabling him to carry out his will. Dionysius had a singular passion for literature, wrote lyrics and tragedies, and it was necessary for every one who sat at his table to praise not less the poet than the warrior. It is said, probably as a sarcastic jest, that Philoxenus, one of his guests, chose the penalty of being sent to work in the quarries rather than listen complacently to some of the tyrant's verses.

DIONYSIUS EXIGUUS (the Little), so named from his small stature, a Roman monk in the early part of the 6th century. He was originally from Scythia, but became abbot of a monastery in Rome, where he died in A. D. 540, during the reign of Justinian. He is praised by Cassiodorus, the best authority of the time, for his great erudition, writing in Greek or Latin with equal facility, and having profoundly studied theology. He gave to the western church the first regular collection of ecclesiastical laws, comprising the canons of the apostles and of several councils, and the decrees of some of the popes. But his chronological labors have given him greater celebrity. He is reputed the founder of the era which for more than 10 centuries has been observed by Christian nations. Before him the Christian era had been calculated from the death of Christ; he first fixed the year of the incarnation in the 753d year of Rome, and this,

at least after the 8th century, was universally adopted as the commencement of the era.

DIONYSIUS OF HALICARNASSUS, a Greek historian and rhetorician, born in Halicarnassus, in Caria. He removed to Rome early in the reign of Augustus, and 22 years later, shortly before his death, published his work, entitled Ῥωμαϊκη Αρχαιολογια, or "Roman Antiquities." It was in 20 books, and contained the history of Rome from the earliest mythical times to the era of the Punic wars, where the history of Polybius begins. There remain only the first 11 books, which stop with the year 441 B. C., a few years after the expulsion of the decemvirs. Several fragments and extracts from the last 9 books have been preserved in the collections made by command of the emperor Constantine Porphyrogenitus in the 10th century. The best editions of his works are those of Hudson (Oxford, 1704) and Reiske (Leipsic, 1774–'6). His rhetorical compositions have been published separately by Gross and by Westermann. There is an English translation of the "Roman Antiquities," by Edward Spelman (4 vols. 4to., London, 1758).

DIONYSIUS THE YOUNGER succeeded his father Dionysius the Elder, as tyrant of Syracuse, 367 B. C. At that time he was a reckless young man, educated in luxury, and unused to public affairs. He hastened to conclude a peace with the Carthaginians, abandoned his father's projects of foreign settlements and power, and devoted himself to pleasure. The philosopher Dion was his uncle, and undertook to excite him to a noble career. He conversed with him of the doctrines of Plato, and through his influence that philosopher was invited to visit the court of Syracuse. On coming, Plato proposed an amendment to the constitution, changing the government from nominal democracy and real despotism to a confederate authority, in which the sovereignty should reside in all the members of the ruling family, who should form together a college of princes. The monarch rejected this proposal, and soon after took up his residence in Locri, and gained some advantages against the Lucanians; but the wild orgies to which he surrendered himself drew upon him the contempt both of his subjects and of foreigners. With a small band of exiles, and with two vessels laden with arms, Dion landed in Sicily (359 B. C.), and was joined by thousands as he marched toward Syracuse. Dionysius had instantly returned from Locri, but his troops were defeated, and he was obliged to retreat to the citadel; and finding it impossible to retain his power, he collected his most valuable property, and sailed away to Italy, while his friends still kept possession of the stronghold. In 346 he availed himself of internal dissensions to recover his power in the city, and continued to reign there during the next 3 years. But the former Syracusan empire was now in fragments; and even the garrison which defended the tyrant in the citadel was rebellious. Timoleon now appeared upon the stage, marched against Syracuse in 343, and Dionysius consented to an arrangement, by which he was allowed to depart in safety to Corinth. He passed the remainder of his life in a private condition, with low associates, performing, according to various traditions, the parts of schoolmaster, actor, and mendicant priest of Cybele.

DIONYSUS. See BACCHUS.

DIOPHANTUS OF ALEXANDRIA, the only Greek writer on algebra, first mentioned by John, patriarch of Jerusalem, in the 8th century, unless he be identical with the astronomer Diophantus, on whose work Hypatia is said by Suidas to have written a commentary. There are no more definite indications of his era. When his MSS. came to light in the 16th century, 13 books of his Αριθμετικα were announced, only 6 of which have been produced. Another treatise by him, Περι των Αριθμων Πολυγωνων ("On Polygonal Numbers"), is extant. These books contain a system of reasoning on numbers with the use of general symbols, and are therefore algebraical treatises, though the demonstrations are written out at length in common language. The term Diophantine was applied by some modern mathematicians, as Gauss and Legendre, to the peculiar analysis employed in investigating the theory of numbers. The similarity of the Diophantine and Hindoo algebra renders it probable that both had a common origin, or that one was derived from the other. The best edition of his works is that of Fermat, in Greek and Latin, published posthumously (Toulouse, 1670). They were translated into German by Schulz (Berlin, 1821). The 6 books of the "Arithmetic" were translated into French by Stévin and Girard (Paris, 1625). A complete translation of his works into English was made by the late Miss Abigail Lousada, but has not been published.

DIOPTRICS, that part of optics which treats of refracted light. See OPTICS.

DIOSCORIDES, PEDACIUS or PEDANIUS, a medical and botanical writer of the 1st or 2d century A. D., probably a native of Anazarbus in Cilicia. He made collections of plants in Italy, Gaul, Greece, and Asia Minor, and wrote a treatise in 5 books on materia medica (Περι Ὑλης Ιατρικης), a work which enjoyed the highest reputation until the 17th century. It is now chiefly valuable as illustrating the opinions of physicians in ancient times, and as giving us some idea of their attainments in natural history. It has been translated into the Arabic, Italian, Spanish, French, and German languages, and many editions of it have been published in Latin and Greek.

DIP, in geology, the inclination of a stratum of rock from a horizontal line. The angle of inclination is measured by an instrument called a clinometer, and the magnetic needle which is commonly with it gives the point of the compass toward which the rock slopes or dips.—In terrestrial magnetism, it is the inclination which a needle makes from a horizontal line after it has been magnetized, when before this it was

perfectly balanced in a horizontal position. In the northern hemisphere the north pole of the needle dips toward the north pole of the earth, and in the southern hemisphere the south pole is depressed toward the south pole of the earth. The line called the magnetic equator, upon which a needle continues in the same horizontal plane before and after it is magnetized, is a curved line, not varying from the geographical equator. From this toward either pole the dip increases in intensity, and by means of a needle constructed with great delicacy, and furnished with a graduated vertical arc, called a dipping needle, the angle is measured and determined for different places upon the surface of the earth. It is found, however, not to be constant in any place, but to follow the motion of the magnetic poles, which appear to move westward at an annual rate of about 11′ 4″. The position of these poles is ascertained by comparison of the angles given by the dipping needle in different latitudes. In 1831 Commander Ross succeeded in reaching the spot in the northern hemisphere calculated to be the N. magnetic pole, lat. 70° 5′ 17″ N., long. 96° 46′ 45″ W., where he found the dipping needle to take a position within 1′ of the vertical, and the compass needles to be as perfectly indifferent to polarity as if they possessed no magnetic properties. For compasses intended to be used over a wide range of latitude, provision has to be made to counteract the effect of dip, in order that the needle may retain a horizontal position. This is effected by a small weight, so adjusted as to be slid along the bar as may be required. In passing from the northern to the southern hemisphere, it must be taken off the south pole of the needle and placed upon the north end. Dipping needles require to be made with the nicest accuracy, and to be free as possible from friction and every other impediment to their motion. By means of a universal joint, or by reference to a variation compass, the needle is made to move always in a vertical plane coinciding with the magnetic meridian of the place. —The dip of the horizon is the angle which a line to the visible horizon makes with a horizontal plane; its magnitude depends upon the height to which the observer's eye is elevated.

DIPHTHERIA (Gr. *διφθερα*, skin), the most recent name of a disease of the mucous membranes first described by Bretonneau as diphtherite, characterized by the exudation of a thick leathery membrane in the throat; it may occupy also any portion of the air passages even to the bronchi, the gastro-intestinal surfaces, the points of junction of the skin and mucous membrane, and the skin itself where it is delicate or deprived of its epidermis. It is allied to some forms of scarlatinous inflammation, to croup, and to quinsy, with which it is often confounded. It is probably, as it has occurred during the last few years in France and England, only an intense epidemic form of an old disease, manifesting itself in various forms of throat disease. In the formation of firm concretions and in its tendency to spread when epidemic, it resembles in some respects the disease of infants known as *muguet*. Various causes have been assigned for it, and it is generally admitted to be a specific disease. Dr. Laycock and others regard it as due to the *oidium albicans*, a parasitic fungus, whose sporules and mycelium have been found on the mucous membrane of the mouth, fauces, and alimentary canal; its irritation induces in the enfeebled membranes an increased secretion of epithelial scales and exudation corpuscles, which with the fungus constitute the membrane or pellicle; it seems to act upon the capillaries of the subjacent tissue, which is red and bleeding. Syphilitic, scarlatinic, or rubeolic inflammation may take on the diphtheritic form during an epidemic, and the fungus may excite an irritation without forming a pellicle; it is not vesicular nor ulcerative like aphthæ, and the redness is deeper. These microscopic parasitic organisms doubtless cause more diseased conditions than physicians are as yet aware of, and the question naturally arises whether the fungous growth is the primary process, or whether it is secondary, requiring the nidus of a previously diseased membrane for its development. From the occurrence of similar growths in a variety of diseases, they would seem a consequence rather than a cause, springing up wherever they find a suitable nidus, complicating and often masking the original disease; the fungus of diphtheria, however, is said to be peculiar, and different from other similar parasites. The sporules may and do pass from one person to another, and the disease is consequently contagious, rendering necessary the isolation of the sick. It is most common in the foul districts of the large cities of France and England, and is attributed to the action of putrid effluvia on the fauces, especially the foul air of sewers and cess-pools; according to the report of the registrar-general, in March, 1858, 2,000,000 of the people of London live over such subterranean structures, so imperfectly secured that any variation in the pressure of the atmosphere forces up the foul air and sends it along every street and into every house, as if it were an apparatus specially contrived for passing currents of poisonous vapor steadily over the people. The same authority states that in 1857 15,000 deaths in London were attributed to the aggregate effects of impure air and other sanitary defects, and recommends the conducting off of the effluvia of these receptacles through pipes running as high as the chimneys. It is altogether probable that many epidemics in this country have had a similar origin, and from the account of the symptoms and successful treatment of the recent epidemic of singular throat disease in Albany, it would seem that it was diphtheria; it was found in all parts of the city, and in almost every block, and raged for several months with a mortality of about 5 per cent.—As diphtheria most severely attacks debilitated constitutions, in addition to hygienic and sanitary measures, the general treatment should be by

antiseptic tonics and stimulants. To destroy the fungous growth, the best local applications seem to be a saturated solution of borax, and alkalies; the chlorate of potash; the liniment of acetate of copper; corrosive sublimate gargles; solutions of the sulphates of zinc, iron, and copper; alkaline, and even common salt gargles. Nitrate of silver, though the most popular, has not proved the most successful application. Wounds affected with the fungus should be treated on similar principles.

DIPLOMACY (Gr. *διπλωμα*, from *διπλοω*, to double or fold), the science or art of conducting the official intercourse of independent states, and particularly of negotiating treaties. The term is of very recent origin, having first come into general use in the courts of Europe since the end of the 18th century. It is not to be found in Johnson's dictionary, and a French writer on the subject states that it is not in any dictionary anterior to 1819. The art itself, however, is as ancient as the division of mankind into peoples and nations. In the earliest periods of history heralds and ambassadors make their appearance, bearing messages from king to king or from state to state. The Romans had a college of heralds, 20 in number, supposed to have been instituted by Numa, whose functions embraced every thing connected with the declaration of war and the making of treaties. But regular and permanent embassies at foreign courts do not seem to have been maintained by any nation until the 16th century A. D. Ambassadors were sent for special occasions, and returned home when they had accomplished the particular object of their mission, or had found its accomplishment impracticable. They were clothed with a sacred, and to some extent a priestly character, and their personal privileges were seldom disregarded even by the rudest barbarians. The heralds whom Darius the Persian king sent to the Grecian cities to demand the symbols of submission, earth and water, some of whom were put to death at Sparta and at Athens, were looked upon less as ambassadors than as bearers of a hostile and insulting message; yet both the Spartans and Athenians afterward expressed their regret for the act, and attributed some of the misfortunes which subsequently befell them to divine judgments for the crime. The peculiar and complicated relations of the Grecian states with each other gave rise to a very active diplomatic intercourse between them, carried on generally by means of formal deputations of envoys, at the head of whom was sometimes placed a man of distinguished eminence. Throughout antiquity, indeed, embassies of importance do not appear to have been confided to the discretion of a single person, but rather to a commission of 2 or 3 or even more of equal rank. Ancient diplomacy appears to have been guided by no other rules than those of apparent self-interest, though to some extent a kind of international law was recognized among the Grecian republics. Engagements and treaties were observed only so long as it seemed profitable to observe or not dangerous to disregard them. To oppress the weak, to deceive the strong, to employ by turns force or artifice as policy seemed to require—such was the aim and such was the art of ancient diplomacy. The Romans professedly regarded all foreign nations as barbarians, to be subdued and made tributary whenever opportunities occurred. They made treaties and formed alliances, but renounced both without scruple when it became convenient to do so. Christianity first elevated diplomacy to a nobler position by teaching the brotherhood of man and of nations, within the pale of the church at least, and by giving them the supreme law of the gospel, and finally, during the middle ages, by recognizing the pope as the supreme head and arbiter of the Christian commonwealth. The most ancient specimens of diplomatic correspondence which have come down to us are those contained in the *Excerpta Legationum*, vol. i. of the Byzantine historians, or the 53d book of the great historical compilation made by order of the emperor Constantine Porphyrogenitus. Among them is a curious account of the embassy of Maximin, a high officer of the Byzantine court, who was sent by the emperor Theodosius, about the middle of the 5th century, on a mission to Attila, the king of the Huns, who received him in his capital on the banks of the Danube, at or near the place where the city of Buda now stands. The details of this mission are highly interesting, and it would seem to have been conducted very much in the manner of an embassy of modern times.—In the middle ages diplomacy partook of the general rudeness, and was comparatively crude and simple. The relations of states were not complicated, and little forethought for any thing beyond immediate emergencies seems to have been exercised by the statesmen of the period, except by the popes, who had almost constantly in view a well-defined policy for extending and strengthening their ecclesiastical dominion. It is to the Italian republics that we owe the first marked development of the science of diplomacy, the characteristic of which is that as far as possible it substitutes reason and intellect for brute force, and teaches respect for justice and the rights of others, and is therefore peculiarly favorable, when not perverted, to weak, unwarlike, and commercial states. The Italian republics, exposed to the attacks of great military monarchies, cultivated diplomacy with peculiar care. Their politicians, conspicuous among whom was Macchiavelli, whose diplomatic correspondence has been pronounced the finest in existence, became celebrated for their unrivalled skill in the science, and it was long the practice of the greater states of Europe to employ Italians in negotiation, on account of their supposed peculiar aptitude for the subtleties of the profession. The ambassadors of Venice were especially famous, and the relations of their missions which they regularly made to the senate have a high reputation among historians, for the deep and accurate insight which

they give into the policy and manners and characters of the courts to which they were accredited. Italian plomacy was in general profound, cautious, and unscrupulous. It occupied itself much in forming combinations and alliances, and did not disdain to buy or bribe ministers, confessors, and mistresses, to corrupt generals, steal or forge documents, and sometimes even to employ poisoning and other forms of assassination to accomplish or promote its objects. These malpractices, however, were not confined to Italy, but characterized the diplomacy of all Europe to as late a period as the 16th century.—A great impulse was given to diplomacy by the fall of the Byzantine empire, the invention of printing and of gunpowder, the discovery of America, and the general intellectual development and political fermentation of Europe in the 15th century. Henry III. of France created the office of minister of foreign affairs in the last year of his reign, and the first minister appointed to it was Louis de Révol, who held the post from Jan. 1, 1589, to Sept. 17, 1594. But it is to the reign of Henry IV. of France (1589–1610) that the origin of the modern system of diplomacy has been traced by writers on the subject. That monarch was served by distinguished statesmen and negotiators, preëminent among them the famous Sully, by whom the forms and usages of diplomacy were brought to a degree of perfection before unknown. Diplomacy, indeed, was a favorite instrument with Henry IV., who was all his life surrounded by singularly delicate and difficult complications of a mixed political and religious character. He was the inventor of the system of mediations, which has often since been found so convenient a mode of averting war without wounding the pride of nations. He had great and comprehensive plans of federation and for the preservation of perpetual peace among the states of Europe, to effect which he relied chiefly upon diplomacy. The despatches of his ambassadors and ministers are remarkable for their ability, sagacity, and elevation of sentiment. Cardinal Richelieu (1624–'42) continued in the foreign policy of France the method of Henry IV., and directed his diplomacy chiefly against the house of Austria. He is generally considered the founder of the present system of maintaining permanent legations at foreign courts, instead of sending special and transient embassies, though long before his time resident embassies were kept by the Venetians at several courts. It was during his administration that French began to supersede Latin as the language of diplomacy in Europe, for which it is peculiarly well adapted by its clearness and precision. Diplomacy greatly enlarged its field of action in the 17th century. Embassies were sent from western Europe to countries that had been hitherto out of the pale of civilized intercourse—to Russia, to Persia, to Siam, and to other remote and barbarous regions. The ambitious and warlike policy of Louis XIV. exercised a marked influence upon the character of the diplomacy of his times. Statesmen occupied themselves incessantly with projects of aggression or defence, and with forming or dissolving leagues and combinations. Aspirations after universal empire were entertained on the one hand, and apprehended on the other. Artifices unknown to primitive diplomacy were freely resorted to, such as secret articles and separate articles in treaties; and it has been suspected that even sham treaties were promulgated to mislead or blind the general public. This period is also remarkable for the number of its treaties for the regulation of commerce and navigation.—During the period between the treaty of Utrecht (1713) and the beginning of the French revolution (1789) the diplomacy of Europe assumed an aspect very different from that of the preceding century. Exhausted by foreign and civil wars, the nations longed for repose. France and Austria saw themselves counterbalanced, and their dreams of universal dominion dissipated, by the appearance of new powers on the stage. Russia and Prussia took their place in the front rank of European nations, while Great Britain acquired the mastery of the seas, and developed prodigiously her commerce, industry, and internal resources. This was an age of intellectual and moral revolutions, which preceded and prepared the stupendous political revolutions that marked the latter part of the century. New ideas, new opinions, new motives, gained admission, and acquired predominant influence in the minds of the ruling classes of Europe, especially in France, Germany, and England. The extension of commerce and the growth of colonies in America, Africa, and the East Indies, led to the remodelling of a branch of diplomatic service, the consular system, and to its restriction within nearly its present limits. —The French revolution and the long wars that sprung from it wrought a great change in the materials and tendencies of diplomacy, by sweeping from the map of Europe a number of effete states, by raising up gigantic combinations against Napoleon and against the revolutionary spirit, and by converting the current of events in Europe from a mere contest for supremacy between monarchs into a conflict of antagonistic principles, and a desperate struggle for existence on the part of the royal and privileged families against the increasing intelligence and aspirations of the people. In 1815 the diplomacy of the great continental powers sought to strengthen itself against revolution by assuming the cloak of sanctity, by forming the holy alliance, the object of which was to maintain what was called legitimacy, to keep things as they were, to regulate as one family the Christian states of Europe, and especially to check the tendencies of the smaller kingdoms toward constitutional government. The diplomatists of this period were remarkable for ability and for the world-wide celebrity that some of them attained, as the Frenchman Talleyrand, the Austrian Metternich, and the Russian Nesselrode. Several very memorable congresses of diplomatists also

distinguished this period, such as that at Vienna (1814), at Aix la Chapelle (1818), at Troppau (1820), at Laybach (1821), and at Verona (1822). The rapid decay of the Turkish empire, and the changes made in it by the separation of Greece and the long revolt of the pasha of Egypt, together with the ambitious designs of Russia, have opened a new and wide field to European diplomacy since 1820, which has been still further enlarged by the renewal of revolutionary outbreaks in 1848, and the revival of the French empire in the person of Louis Napoleon in 1852. The prodigious growth of the United States of America during the same period has also introduced a new and peculiar element into diplomacy, by raising to the position of a power of the first rank a republic which does not acquiesce in all the principles of international law established by the monarchies of Europe, and holds itself entirely aloof from the sphere of their traditional policy. In practice, the diplomacy of the United States, inaugurated by Franklin, Adams, Jay, and Jefferson, has maintained an honorable reputation for directness, intelligence, and success, though, unlike all other civilized governments, the republic does not maintain a regularly trained corps of diplomatic agents especially educated for and devoted to the profession. Among the most striking instances of the success of American diplomacy may be mentioned the negotiations conducted by Commodore Perry and Mr. Townsend Harris, which have resulted in opening Japan to the commerce of the world. More recently the chief exertions of American diplomacy have been directed to the condition and destiny of the island of Cuba and of the Spanish American republics. A line of policy in these quarters, marked by novel and decided features, was shaped out under the administration of President Pierce, and continued by President Buchanan, of which the fullest expositions are contained in the document commonly called the Ostend manifesto, though it was actually issued from Aix la Chapelle (1854), and the annual message of President Buchanan in 1858.—The superintendence of the diplomatic relations of a country is in modern times, and among civilized nations, generally intrusted to a particular officer of state, who, on the continent of Europe, is usually styled minister of foreign affairs (in some instances the prime minister is at the same time minister of foreign affairs); in England, the secretary of state for foreign affairs; in the United States, simply the secretary of state. The appointment of diplomatic agents belongs to the executive, though in the United States the appointment must be confirmed by the senate. The highest grade of diplomatic agent is that of ambassador. In the diplomacy of the Roman Catholic states of Europe the legates and nuncios of the pope take rank with the highest class. The second grade of diplomatic agents includes envoys, ordinary and extraordinary, ministers plenipotentiary, the internuncios of the pope, and all agents accredited directly to sovereigns. The third order of diplomatic agents, chargés d'affaires, are, with few exceptions, accredited not to the sovereign of the country to which they are sent, but to the department of foreign affairs. The diplomatic agents of the United States are classed, by act of congress, 1856, as ambassadors, envoys extraordinary and ministers plenipotentiary, ministers resident, commissioners, and chargés d'affaires. Consuls-general and consuls are also sometimes invested with diplomatic powers in countries where the United States have no other authorized representatives. —See Marten, *Précis du droit des gens modernes de l'Europe* (new edition, Paris, 1857).

DIPLOMATICS, the science of the knowledge of ancient documents, and especially of their age and authenticity. The charters of grants from sovereigns to individuals and corporations were formerly called diplomas, and the word is applied to all letters, documents, and pieces of writing of a public nature that have come down to us from the middle ages and the subsequent centuries. The public documents of the ancients, that is to say, of the Greeks and Romans, have perished, except such as were inscribed on stone or metal. But a vast mass of MSS. of the middle ages exists in Europe, whose dates and authenticity can only be settled by careful and skilful investigation. The quality of the parchment or paper, and of the ink, and the style of the handwriting, afford the means which are relied upon by those versed in the science of diplomatics to determine the age of the document. Formerly ink was made of soot, and red ink made of vermilion was sometimes used. Those who apply themselves to the study of diplomatics can easily distinguish the ink and the parchment and paper of one epoch from those of another. The variations in handwriting are also so great that by the character alone it is possible to pronounce within 40 or 50 years when any diploma was written. In Europe the study of diplomatics has been much cultivated. The standard book of reference on the subject is the *Nouveau traité de diplomatique, par deux Bénédictins* (6 vols. 4to., Paris, 1750).

DIPTERA (Gr. δις, twice, and πτερον, wing), an order of insects, containing the fly, mosquito, &c., characterized by 2 wings, 2 knobbed threads (*halteres*, balancers or poisers) behind the wings, and a horny or fleshy proboscis. They undergo a complete transformation; the larvæ, usually called maggots, have no feet, and have the breathing holes generally in the posterior part of the body; the pupæ or nymphs are either incased in the dried skin of the larvæ, or naked, showing the wings and legs free and unconfined. The head is large, globular, connected with the body by a very slender neck, and is capable of a considerable pivot-like motion; the greater part, especially in the males, is occupied by the brilliant compound eyes, the single ocelli, when they exist, being on the top of the head. Under the head is the proboscis

or sucker, which in some kinds can be drawn up and concealed in the mouth; it consists of a long channel, ending in 2 fleshy lips, and enclosing on its upper side from 2 to 6 fine bristles, sharp as needles, and making the punctures so familiarly known in the case of mosquito bites; as this apparatus takes the place of the jaws of other insects, these wounds may properly be called bites. The saliva which flows into the wounds causes the well-known swelling and itching, the irritation in some skins amounting to inflammation. The sheath serves to maintain the lancets in position, and the latter having made their punctures form a groove along which the vegetable or animal fluids rise by the suctorial power of the insect and the force of capillary attraction. In the flies which only lap their food the proboscis is large and fleshy. The antennæ in the gnats are long and many-jointed, in the flies short and thick, at the base of the proboscis. The wings are generally horizontal, delicate, with many simple veins in them; the posterior wings are metamorphosed into the balancers or poisers. Some entomologists, as Latreille, think the poisers do not correspond to posterior wings, but are vesicular appendages connected with the posterior respiratory tracheæ of the chest. Just behind the wing joints, and in front of the poisers, are 2 small convex scales, opening and shutting with the wings, and called winglets. The thorax is often the hardest part of the insect, composed principally of the intermediate mesothorax. The abdomen is not always united to the thorax by the whole of its posterior diameter, and in many females ends in a retractile jointed ovipositor by which the eggs are deposited. The legs, 6 in number, are usually long and slender, with 5 articulate tarsi and 2 claws at the end, beside 2 or 3 little cushion-like expansions, by means of which they are able to ascend the smoothest surfaces and to walk with the back downward with perfect security. According to Marcel de Serres, the dorsal vessel (the heart) in diptera is narrow and its pulsations frequent. Respiration in the adult is carried on by vesicular and tubular tracheæ. The nervous system consists of an aggregate of cerebral ganglia, and in some of 9 other ganglia, 3 in the thorax and 6 in the abdomen, connected by longitudinal simple commissures or cords; the larvæ have usually one more pair of ganglia than the adults, and have the commissures often double. The proboscis being the transformed under lip, often geniculate, the perforating bristles may be regarded as maxillæ, mandibles, and tongue. In those larvæ which have a distinct head, as in the mosquito, the jaws are arranged for mastication, though some of the pieces are wanting; but in the acephalous maggots the mouth is suctorial. Communicating with the gullet is a thin-walled vesicle, the sucking stomach, in which the fluids swallowed are temporarily deposited; the stomach proper is long and narrow, and makes many convolutions in the abdomen. The end of the intestine is short, muscular, and pyriform. The uriniferous vessels are long, and generally 4 in number, opening into the lower extremity of the stomach; the ovaries consist usually of numerous short 3 or 4-chambered tubes, terminating in a short or a convoluted oviduct; the testicles are 2, simple, and generally of an oval or pyriform shape, with long vasa deferentia ending in the ejaculatory duct in common with 2 simple accessory mucous glands, and with horny valves enveloping the projecting copulatory organ. The larvæ, or maggots, are without legs, generally whitish, and vary exceedingly in form and habits; the larvæ of the mosquito are aquatic, breathing with the head downward through the tubular tail surrounded with feather-like appendages, and the pupæ tumble about in water by means of 2 oval fins. These larvæ, and those of most flies which have 4 or 6 bristles in the proboscis, have a distinct horny head, and cast their skins to become pupæ, which are generally of a brownish color; many have thorns and prickles on the body by which they work their way out of their coverings; a few cover themselves with silken webs and spin cocoons. The larvæ of other flies, with a soft retractile head, living by suction, increase rapidly in size, and change their form without casting off their skins, which shorten and harden, forming a case within which the larva changes into a pupa, which comes forth a fly by forcing off one end of the case. Though this order contains the bloodthirsty mosquito, the disgusting flesh fly, and many insects depositing their eggs in the bodies of living animals, it is a most useful one, supplying food to insectivorous birds, and themselves consuming decomposing animal and vegetable substances which would otherwise infect the air. Their life in the perfect state is short, very few surviving the rigor of winter. Among the genera with many-jointed antennæ the following are the most interesting and best known: *Culex* (Linn.), containing the well-known gnats and mosquitoes, whose larvæ and pupæ are so common in stagnant water, called wigglers and tumblers, and whose adult females pierce with their lancets and annoy by their nocturnal hum the human race from Lapland to the tropics; the best known species are the *C. pipiens* of Europe, and the *C. Americanus* of this country, which is probably distinct. The genus *cecidomyia* (Latr.) includes many species interesting to the agriculturist, as the Hessian fly (*C. destructor*, Say), the wheat fly (*C. tritici*, Kirby), the willow gall-fly (*C. salicis*, Fitch), injurious in the larva state. The genus *tipula* (Linn.), especially the *T. oleracea* (Linn.), commonly known in England by the name of Harry Long-legs, is noted for its depredations in the larva condition on the tender roots of meadow plants. In the genus *simulium* (Latr.) are the black fly and the midges of the northern parts of this country; the black fly (*S. molestum*, Harris) fills the air during the month of June in Canada and the northern states; it flies in the daytime, and is so savage that every bite draws blood, in some

skins accompanied by considerable irritation; it is black, with transparent wings, and about $\frac{1}{10}$ of an inch long. After continuing through June, it is followed by another species (*S. nocivum*, Harris), called "no-see-'em" by the Indians of Maine from their minuteness; they come forth toward evening, creep under any kind of garment, and produce a sharp, fiery pain without drawing blood; they are very troublesome to travellers and new settlers in July and August. Among those with few joints in the antennæ is the genus *tabanus* (Linn.), which contains the large horse flies, as the *T. bovinus* (Linn.), of a dark brown color, and an inch long, common in Europe, where there are more than 40 other species; the most common of the American species are the *T. atratus* (Fabr.), of a black color, with a whitish bloom on the back; the eyes are very large, of a shining black color, with 2 jet-black bands across them; it is about an inch long, with an expanse of wings of 2 inches; the orange-belted horse fly (*T. cinctus*, Fabr.) is smaller and less common, black, with the first 3 rings of the body orange; a smaller species is the *T. lineola* (Fabr.), with a whitish line along the top of the hind body. In the summer these flies are very troublesome to cattle and horses, being able to pierce through the thickest hide with their 6-armed proboscis; a strong decoction of walnut leaves applied as a wash is said to keep them off. The golden-eyed forest flies (*chrysops*, Meig.) are known by their brilliant spotted eyes and their banded wings; smaller than horse flies, they resemble them in their habits, frequenting woods and thickets in July and August; some are wholly black, others striped with black and yellow. The bee fly (*bombylius æqualis*, Fabr.) flies with great swiftness through sunny paths in the woods, hovering over flowers and sucking their honey, like humming birds; it is about $\frac{3}{4}$ of an inch long, shaped like a humble-bee, and covered with yellowish hairs; the expanse of the wings is about an inch; they are divided longitudinally into 2 equal parts by the colors, the outer half being dark brown and the inner colorless. Among the flies which prey on other insects, seizing them on the wing or on plants, is the genus *midas* (Latr.), of which the orange-banded species (*M. filatus*, Fabr.) is sometimes $1\frac{1}{4}$ inches long and $2\frac{1}{4}$ inches in expanse of wings; the general color is black; it frequents the woods in July and August, where it may be often seen flying or basking in the sun; the larva is a cylindrical maggot, growing to the length of 2 inches; the pupa measures $1\frac{1}{4}$ inches in length, is of a brown color, with forked tail, 8 thorns on the fore part of the body, and numerous sharp teeth on the edges of the abdominal rings; it pushes itself half out of its hole when the fly is about to come forth. The genera *laphria* (Fabr.) and *asilus* (Linn.) are also predaceous in the winged state; in the former the antennæ are blunt at the end, in the latter slender-pointed; the former resemble large humble-bees in their thick and heavy bodies and legs; in the larva state these asilians live in the ground, where they do much mischief to the roots of plants. The soldier flies (*stratiomydæ*) have 2 spines on the hinder part of the thorax; the proboscis contains only 4 bristles, and ends with fleshy lips adapted for sucking vegetable juices; they are fond of wet places, and their larvæ live in stagnant pools, some thrusting their breathing tube out of the water; they undergo transformation within the hardened larval skin. The genus *stratiomys* (Geoff.) has a broad oval body, of a dark color, with yellow markings on each side, and the antennæ somewhat spindle-shaped. The genus *sargus* (Fabr.) is said to have no spines on the thorax, a slender body, of a brilliant grass-green color, about $\frac{1}{2}$ an inch long, with a bristle on the end of the antennæ. These insects delight in sunny weather, being dull and inactive in cloudy days; the larvæ are found in dung and rich mould. The *syrphidæ* have also a fleshy proboscis, and live on the honey of flowers; they resemble bees, wasps, and hornets in the shape and colors of their bodies, and they sometimes lay their eggs in the nests of these insects; others drop their ova among plant lice, which the young eagerly feed upon. The larvæ of the genus *helophilus* (Meig.) were named by Réaumur rat-tailed maggots, from the great length of their tubular tails, which serve as respiratory organs; the experiments of Réaumur show that while the insect lies concealed in mud, its respiratory tube may reach 5 inches to the surface of the water; it seems to be composed of 2 portions, which slide one into the other like the joints of a telescope; some of the larvæ of this family live in rotten wood. The family *conopidæ* resemble slender-bodied wasps; the antennæ are long and 3-jointed; the proboscis long, slender, and geniculate. The genus *conops* (Linn.) is generally of a black color, and about $\frac{1}{2}$ an inch long; more than 20 species are described, usually found on flowers in June and July, but not in large numbers; the females deposit their eggs in the larvæ and the perfect insects of the humble-bee, in whose bodies their young undergo metamorphosis. The common stable fly belongs to the genus *stomoxys* (Fabr.); the flesh fly to the genus *sarcophaga* (Meig.); the house fly and the meat fly to the genus *musca* (Linn.); the flower flies to the genus *anthomyia* (Meig.); the cheese fly to the genus *piophila* (Fallen.); the dung fly to the genus *scatophaga* (Meig.); the fruit and gall flies to the genera *ortalis* (Fallen.) and *tephritis* (Latr.); these will be described in the article FLY. The gadflies or bot flies, comprising the genera *œstrus* (Linn.) and *gasterophilus* (Leach), affecting respectively the ox and the horse, will be described under GADFLY. Various winged and wingless ticks, infesting the horse, sheep, and birds, belonging to the order of *diptera*, but forming with the spider flies the order *homaloptera* of Leach and the English entomologists, will be treated in the article TICK; they include the genera *hippobosca* (Linn.), *melophagus* (Latr.), and *ornithomyia* (Latr.).—At the

end of this order may be mentioned the genus *nycteribia* (Latr.), the spider fly, a wingless insect resembling a spider; the small head seems a mere tubercle on the anterior and dorsal portion of the thorax; the eyes are like minute grains; the thorax is semicircular; the antennæ are extremely short, inserted close together, and immediately in front of the eyes. This genus nestle in the hair of bats, among which they move with great rapidity; according to Col. Montagu, when they suck the blood of bats they are obliged to place themselves on their backs on account of the dorsal position of the head. This last division of the *diptera* is not produced from eggs deposited in the usual manner, but the larva is hatched and developed within the body of the mother, and is not born till it arrives at the state of pupa; hence these genera have been called *pupipara* by Latreille; the pupa when born is nearly as large as the parent, enclosed in a cocoon, the altered skin of the larva at first soft and white, but soon growing hard and brown; it is notched at one end, where the mature insect escapes. The order of *diptera* makes up for the small size of its members by their countless swarms.

DIPTYCHA (Gr. δις, twice, and πτυξ, fold, tablet), registers used during the first Christian centuries, formed of 2 tablets of wood or ivory, upon which were inscribed the names of those most distinguished in church and state. They were thus of 2 kinds, the sacred and profane. On the former were catalogued the names of popes, bishops, martyrs, founders of religious establishments, and in general all benefactors of the clergy. The names of the living were on one side of the tablet, and of the dead on the other. It was the deacon's office to recite these names during the service. The profane diptycha belonged especially to the consular dignity, and upon their tablets were engraved the name and titles of the consul, and also animals and gladiators as symbols of the games which he was going to exhibit to the public in entering upon his duties. Every consul after his nomination had several of these diptycha, which he distributed among his principal officers, as modern princes sometimes send their portraits to privileged favorites.

DIRECTORY, Executive (Fr. *directoire exécutif*), the name given to the executive government of the first French republic by the constitution of Fructidor, year III. (Aug. 1795). This constitution was framed by the moderate republican party, whose influence prevailed in the convention after the fall of Robespierre and the committee of public safety, and was adopted in the primary assemblies of the people. The legislative power was vested by it in 2 assemblies, the council of 500, and the council of ancients, which numbered half as many members, aged at least 40. Both were chosen by graduated elections, and $\frac{1}{3}$ of each were renewed every year. The former had exclusively the right of proposing laws, the latter that of sanctioning them. The judicial authority was committed to elective judges. The executive directory consisted of 5 members, and was chosen one each year by the council of ancients from a list of candidates presented by that of 500. The directory promulgated the laws and enforced their execution, appointed the ministers and other principal functionaries of the state, had the management of the military and naval forces, finances, and foreign affairs, and the right of repelling hostilities, though not of declaring war. The directors received a large salary, the palace of the Luxembourg as their residence, and a guard of 240 men. They were responsible, decided questions by a majority vote, and presided by turns 3 months each, the presiding member having the signature and the seal. During their term of office none of them could have a personal command, or absent himself for longer than 5 days from the place where the councils held their sessions, without their permission; and after they had left office they could hold no command for 2 years, nor be reëlected for 5. In those days of violent struggles at home and abroad, the balance of power established by this constitution excited antagonism between the different branches of the government, and usurpations followed as a natural consequence. The convention decreed, by a law not included in the constitution, that in the first election $\frac{2}{3}$ of the members of the 2 councils should be chosen from its own body. This arbitrary act led to violent agitations in Paris, and finally to an insurrection of the royalist sections on the 13th Vendémiaire (Oct. 5, 1795), which was suppressed by Barras and Bonaparte. The convention having held its closing session on Oct. 26, the 2 councils held their first on the 28th, and on Nov. 1 elected Barras, Laréveillière-Lépeaux, Rewbell, Letourneur, and Carnot, as directors, all of whom had voted for the death of Louis XVI. Their first proclamation, written on a broken table in a destitute room of the Luxembourg, promised a firm rule, and inspired confidence; and in spite of the exhausted position of the state, the terrible depreciation of the currency, the destitution of the army, and a pressing famine, trade, speculation, and even luxury soon revived. The democratic and communistic conspiracy of Babeuf was easily suppressed (May, 1796). Carnot organized the armies, and directed their movements and victories; Moreau received the command of the army of the Rhine, Jourdan that of the Sambre and Meuse; Hoche suppressed the insurrection in the Vendée, and Bonaparte conquered Italy. But the elections of the year V. (May, 1797) gave the royalists a preponderance in the councils, which was supported by the minority of the directory, while Barras, Laréveillière, and Rewbell sided with the minority in the legislative bodies. The movements of the royalists became more and more threatening, when the majority of the directors agreed to save the republic by an act of violence. This was executed with the aid of the army on the 18th Fructidor (Sept. 4, 1797). More than 50 members of the 2 councils, with Carnot and Barthélemy, who had

replaced Letourneur, and a number of other influential persons, were condemned to transportation, and a persecution of both royalists and anarchists was commenced. Merlin of Douai and François of Neufchâteau were substituted for the 2 proscribed directors, of whom Carnot escaped to Germany. Saved by the army of the interior, the republican rule was maintained by the victories and extortions of the armies abroad. The treaty of Campo Formio was concluded; Switzerland and the states of the church were overrun and revolutionized; Bonaparte was sent to Egypt to attack indirectly England, the only remaining enemy of the republic. But the extreme revolutionary party carried the elections for the year VI. (May, 1798), a part of which were annulled by another violation of the constitution. A new coalition against France was formed. The state was exhausted and avowedly bankrupt. Switzerland and Italy were lost as rapidly as won. The republicans, too, were impatient of the dictatorial rule of the directory, in which Treilhard had replaced François, and Sieyès, an enemy of the directorial constitution, was now elected (May 16, 1798) instead of Rewbell. Finally the councils, having declared themselves permanent, compelled Treilhard, Merlin, and Larévellière to resign on the 30th Prairial (June 18, 1799). Barras saved his office by the desertion of his associates, and maintained himself with Sieyès and the 3 new directors, Gohier, Moulins, and Roger Ducos, till the 18th Brumaire (Nov. 9, 1799), when Bonaparte, suddenly returning from Egypt, by a bold *coup d'état* overthrew the directory and the constitution, and became master of France under the title of consul. The directory ruled France 4 years and a few days, and had altogether 13 members, of whom only Barras officiated during the whole period.

DIS, a contraction of *dives*, rich, the Latin name of Pluto (the giver of wealth), and hence sometimes of the lower world. He was especially worshipped among the Gauls, who believed themselves his descendants, and therefore reckoned their time by nights instead of days.

DISCIPLES, Church of the. The religious body, variously designated as "Disciples of Christ," "Christians," the "Church of Christ," &c., resulted from an effort to effect union among the Protestant denominations in western Pennsylvania. In the beginning of the present century several religious movements for this purpose occurred in different parts of the United States, independently of each other, and without preconcert. The one which gave immediate origin and distinctive character to the body now known as "Disciples," was initiated in 1809 by Thomas Campbell, a preacher of piety and distinction among the Seceders, aided by his son Alexander, to whose ability and energy its successful progress is mainly attributed, and by whom it has been chiefly directed. The original purpose was to heal, if possible, the divisions of religious society, and to develop and establish a common basis of Christian union. It was thought that these desirable objects could be attained by taking the Bible alone as a guide, and its express teachings as the only authoritative standard of faith and practice, allowing meanwhile entire liberty of opinion in relation to all matters not fully revealed. Upon these principles a considerable society was formed, consisting chiefly of members from Presbyterian churches, and meetings were held statedly for the promotion of the cause of union and for religious worship and instruction. After some time, the question of infant baptism, and, as connected with it, the use of sprinkling as baptism, became matters of investigation in the society, and it was finally after some months decided by a large majority that there was no Scripture warrant for either practice, and that consequently, upon their own principles, they were compelled to renounce them. Becoming then a society of immersed believers, they soon after were united with the Redstone Baptist association, stipulating, however, in writing, that "no standard of doctrine or bond of church union, other than the Holy Scriptures, should be required." By means of this union with the Baptists, the principles and views of the Disciples, ably developed and defended by Alexander Campbell in his writings and public discussions, were widely disseminated, and adopted by many. Meanwhile, the diligent study of the Scriptures, contemplated as it were *de novo*, and from a standpoint outside of all denominational and sectarian lines, led by degrees to the discovery and introduction of several characteristics of primitive Christianity which, as the Disciples held, had been long overlooked and neglected. Among these, a prominent one was "baptism for the remission of sins." As the apostle Peter, to whom the keys of the kingdom of heaven were committed, commanded believing penitents who asked what they should do to be "baptized in the name of Christ for the remission of sins," and in order that they "might receive the gift of the Holy Spirit" (Acts ii.), it was believed that the same answer should still be given to such inquirers, and that it was the divine plan thus to impart through the significant institution of baptism that assurance of pardon which many in modern times have been taught to seek in vague emotional impressions. This became therefore a distinguishing feature of the reformation urged by the Disciples. Another characteristic was the practice of weekly communion, after the example of the primitive church. In pressing these matters upon the acceptance of the Baptists, a spirit of opposition was at length aroused in various quarters, especially in Virginia and Kentucky, and a separation to some extent ensued, many of the Baptists remaining connected with the Disciples. Not long afterward, at the close of 1831, their numbers were still further augmented by a union between them and a numerous body which had originated in Kentucky and some other western states, under the labors of B. W. Stone and others, who, some years prior to the movement

led by Thomas and Alexander Campbell, had separated from the Presbyterian communion, and in like manner attempted to effect a union of Christians upon the Bible alone. These reformers, readily adopting baptism for remission of sins, and the ancient order of things as practised by the Disciples, became entirely assimilated with the latter. Since this period there has been a great and constantly increasing accession both from the world and from other religious denominations, and it is believed that the number of members in the United States is now about 300,000. There are many churches also established in British America, in Great Britain, and in Australia. Although the Disciples reject creeds as bonds of fellowship, and disapprove of the technical language of popular theology, holding themselves bound to speak of the "things of the Spirit" in the language of Scripture, they do not materially differ from the evangelical denominations in their views of the great matters of Christianity. The following synopsis from the pen of Alexander Campbell is a fair expression of their sentiments on the points involved: "1. I believe that all Scripture given by inspiration of God is profitable for teaching, for conviction, for correction, for instruction in righteousness, that the man of God may be perfect and thoroughly accomplished for every good work. 2. I believe in one God, as manifested in the person of the Father, of the Son, and of the Holy Spirit—who are, therefore, one in nature, power, and volition. 3. I believe that every human being participates in all the consequences of the fall of Adam, and is born into the world frail and depraved in all his moral powers and capacities, so that without faith in Christ it is impossible for him, while in that state, to please God. 4. I believe that the Word, which from the beginning was with God, and which was God, became flesh and dwelt among us as Immanuel or 'God manifest in the flesh,' and did make an expiation of sin, 'by the sacrifice of himself,' which no being could have done that was not possessed of a superhuman, superangelic, and divine nature. 5. I believe in the justification of a sinner by faith without the deeds of law, and of a Christian, not by faith alone, but by the obedience of faith. 6. I believe in the operation of the Holy Spirit through the word, but not without it, in the conversion and sanctification of the sinner. 7. I believe in the right and duty of exercising our own judgment in the interpretation of the Holy Scriptures. 8. I believe in the divine institution of the evangelical ministry; the authority and perpetuity of the institution of baptism and the Lord's supper." ("Millennial Harbinger" for 1846, p. 385.) It is proper to remark, however, that with the Disciples the Christian faith does not consist in the belief of these or any other tenets as intellectual conceptions of religious truth, but in a simple trust or personal reliance on Christ as the Son of God and the Saviour of sinners. They hence require of candidates for baptism no other confession of faith than this, following the example of Philip (Acts viii. 37). As to government, each church is independent, but the churches coöperate with each other in sustaining Bible societies and missionaries at home and abroad. Two classes of officers are recognized, elders or bishops and deacons, who are chosen by the members of each church, and to whom the interests of the congregation are confided.

DISCORD, in music, a combination of sounds inharmonious and disagreeable to the ear, so called in opposition to concord. Discords are employed to relieve a succession of pure concords, being as necessary in music as shade is in painting, and are introduced by certain preparatives and succeeded by concords to which they have a relation.

DISCOUNT, a sum of money deducted from a debt due at some future period in consideration of immediate payment. In commercial transactions it is customary, when a bill is to be discounted, to pay to the holder or presenter the amount minus the simple interest calculated for the time the bill has to run. Thus a person holding a bill for $100 payable in one year at 7 per cent. would receive $93, which would be considered its present value. The true discount, however, of any sum for any given time, is such a sum as will in that time amount to the interest of the sum to be discounted. Thus, in the above instance, the sum to be deducted from the bill would be, not $7, but $6 54 and a fraction, which would amount at the end of a year to $7. The true rule for computing discount would therefore be: "As the amount of $100 for the given rate and time is to the given sum or debt; so is $100 to the present worth, or so is the interest of $100 for the given time to the discount of the given sum." Elaborate tables have been calculated on this principle, but as abatement of the simple interest is generally resorted to, they are of little practical value.—Discount on merchandise, sometimes called Rebate, is a deduction of so much per cent. from the price of goods sold on credit when the buyer finds means to make his payment before the stipulated time.

DISCUS, among the ancients, the name of a circular mass of stone or metal, used for throwing, as an exercise of strength. This practice was of great antiquity among the Greeks. Homer gives an account of a trial of strength of this kind at the funeral games in honor of Patroclus. In this case the discus was a large globular mass of iron. Ordinarily it was of a flattened form, and about 10 or 12 inches in length, so that when held in the hand ready to be thrown, it would extend a little above the middle of the forearm.

DISINFECTANTS, substances used to counteract or destroy noxious odors and exhalations, or whatever may produce infection. The term is also made to embrace substances used to prevent decay of organic bodies, such as may be found treated of in the articles Antiseptics and Embalming. In the present article disinfect-

ants will be considered as agents for deodorizing and fumigating. As the causes of infection exist in the atmosphere, and are spread over wide districts, disinfectants properly include whatever is made use of to purify the air, and the term may even be applied to the means employed to prevent the formation of noxious miasmata, as to a proper system of drainage, the destruction by fire of vegetable matter exposed to decay, the thorough ventilation of buildings, the provisions for abundant supplies of pure air and light, and the free use of clear water for washing away unclean matters. No more powerful disinfectant exists than the fresh wind, which stirs up the infectious vapors, dilutes them with pure air, and sweeps them away. The great plague of London was preceded by an unusual calm. Violent winds, as hurricanes, are observed to arrest the progress of disease; efficient ventilation has in many hospitals reduced its ravages to a wonderful extent. The light and warmth of the sun has also an extraordinary influence in promoting health and vigor, and destroying some of the causes of injurious exhalations. Though the nature of the action of light upon the animal system is little understood, its beneficial effects are too well established for its claim as an important natural disinfectant to be disregarded. Other agents are abundantly provided by nature which man may employ to remove infectious matters. They may be swept away by running water, or their gaseous emanations be absorbed by the earth in which they are buried. Exposure to heat may change their properties, or cause their elements to enter into new and harmless combinations; or by a freezing temperature decomposition may be arrested, and the formation of noisome gases prevented. Peat bogs present their antiseptic qualities as means of accomplishing the same end, and the astringent extracts of the bark of trees, such as are employed in tanning, possess the qualities of disinfectants.—In the selection and preparation of these agents, none is found more efficient than that which imitates the great natural disinfectant, a strong current of heated air. The method of artificially applying it to the removal of noxious effluvia from clothes and articles of merchandise has been patented in Great Britain, and introduced into various manufacturing establishments. The articles are exposed in large chambers to rapid currents of air, heated from 200° to 250° F. The infectious matters present are decomposed by the heat, or swept off in the hot blasts, while these are kept at too low a temperature for the fabrics to be injured by them. It is a method highly recommended for the use of hospitals, quarantine stations, and other establishments particularly subject to infectious diseases. Earth and porous bodies generally are employed to absorb injurious vapors; none possess this property in so remarkable a degree as charcoal. De Saussure found that a single volume of this substance, prepared from boxwood, absorbed 90 volumes of ammonia; of sulphuretted hydrogen it took up 55 times its own bulk; of carbonic acid, 35 times; of carbonic oxide, 9.42; of oxygen, 9.25; of nitrogen, 7.50; and of hydrogen, 1.75. Bodies of animals have been buried in charcoal powder, which, while it did not prevent decay, still arrested all escape of disagreeable odors. The gases it retained indicated that it exerts an influence in causing the decomposition of the exhalations, and the combination of their elements to form new compounds with the oxygen of the air. These properties have caused it to be introduced in the form of coarse grains into a metallic respirator, intended to be worn over the mouth where noxious vapors are present in the air, and it is recommended to be used for preventing the escape of bad odors from putrefying substances, though it has no effect as an antiseptic to arrest their decay. Chlorine, which has for many years been in use in hospitals and other places exposed to noxious exhalations, acts as a powerful disinfectant by producing a chemical change in the injurious compounds, and also by arresting decay. It is generated by the decomposition of hydrochloric acid, which is effected by adding to it some black oxide of manganese, and convenient vessels are prepared for producing the gas as may be required, in large or small quantities. The chloride of lime, as it is commonly known, is the usual medium, however, for distributing it, the gas being freely evolved on the exposure of the salt to the air. It is set free by the presence of any acid fumes, and as carbonic acid is evolved in the decomposition of organic matters, the noxious effluvia themselves provide one of the agents for their own disinfection. Vinegar or dilute sulphuric acid, however, added to the chlorinated lime, causes a more rapid evolution of the disinfecting gas. In consequence of the acrid nature of the vapor, it should be used for fumigating rooms only when these are not occupied by invalids; and the same may be said of the disinfecting solutions, as of the hyperchloride of soda, of which chlorine is the active agent. The more powerful fumes of nitrous acid, which possess the highest disinfectant qualities, are liable to the same objection; yet so important is their application regarded that Dr. Carmichael Smyth, who first proposed their use, received therefor from the British government the sum of £5,000. The unwholesome sulphuretted hydrogen is decomposed by these fumes, as it is by chlorine, the sulphur being set free and the hydrogen uniting with the disinfectants. In combination with some of the metals, chlorine has been much used as a disinfectant, especially with zinc, in the aqueous solution of the chloride of the metal, which is known as the disinfecting fluid of Sir William Burnett. Its use is somewhat objectionable, from its poisonous qualities. The same compound is advantageously applied to arresting that form of decay in timber called dry rot. Its properties as a disinfectant are fully treated in the reports of the British navy, extracts from which may be found in the "London Medical Times and Gazette," Oct. 1853.

Chloride of manganese is an efficient salt of similar properties, and being the refuse of chlorine manufacture, may be cheaply procured. The sesquichloride of iron is another cheap and efficient agent of this class. It is prepared by dissolving calcined iron pyrites in strong hydrochloric acid. Its use is attended with none of the objections belonging to the poisonous metallic combinations with chlorine. Nitrate of lead has been recommended for its disinfectant properties, particularly in the solution known as Ledoyer's disinfecting fluid. It corrects the fetid odors of sulphuretted hydrogen and hydrosulphuret of ammonia by decomposing these compounds, but it has no antiseptic properties, and is objectionable on account of its cost and poisonous nature.—None of the agents yet named combine so many advantages as sulphurous acid and its compounds with lime or magnesia. In the form of fumes from burning sulphur it has always been highly esteemed for its purifying nature, and its chemical action upon organic compounds has long been applied in bleaching. Beside the property of decomposing and thus destroying effluvia, it also acts as an antiseptic, checking fermentation and the formation of putrid substances. The objection to its use is its own suffocating odor. This is avoided by using the acid in combination, as in the form of sulphate of soda, an excellent antiseptic for purposes of embalming. Combined with lime and magnesia, it is recommended as the best of all disinfectants. It is thus prepared by the patentees, Dr. R. Angus Smith and Mr. A. McDougall, of Manchester, England; and so highly is it approved that the British government have ordered it to be furnished to every transport ship containing horses. Applied to manures, it destroys the disagreeable smell without impairing their properties as fertilizers; on the contrary, the salts of which it is composed, even if in great excess, act themselves as stimulants to vegetation on being converted into sulphates, as they are when spread upon the ground. In treating of its qualities Dr. Muspratt, in his "Chemistry," remarks as follows: "When magnesia is united with sulphurous acid, the most effective, perhaps the only compound capable of serving both ends" (deodorizing and preserving from putrefaction), "is then produced. Metallic salts have no beneficial action on manures; magnesia alone preserves the phosphoric acid and the ammonia. To the mixture already mentioned a few per cent. of carbolic acid, or rather of carbolate of lime, are added; the latter has been found by experience to assist in destroying one portion of the odor with great rapidity. Being a fine, dry, white powder, it absorbs moisture in stables, &c., wherever it is deposited; metallic salts, on the contrary, must be in solution, and the wet is injurious, not only to the hoofs, but also to the health generally of cattle. In the sick room it is said to preserve the atmosphere, when sprinkled on offensive substances, in great purity. In the veterinary hospitals of barracks it has been proved to be very valuable. . . . . A disinfectant uniting efficiency, cleanliness, agreeable manipulation, and cheapness in an equal degree with this will not be easily found."

DISLOCATION (Lat. *dis*, apart, and *locus*, place), a term used by geologists to indicate that change which takes place in the position of rocks when torn from their original place, either by upheaval or subsidence.—It is most commonly applied, however, to that displacement in the osseous structure which results from the direct application of force or other long-continued cause. All the joints are liable to dislocation, but it most commonly occurs to those which possess the greatest mobility; hence the shoulder joint is of all others the most frequent seat of this accident. The head of the humerus or bone of the upper arm, forming a ball and socket joint in connection with the scapula or shoulder blade, is regulated in its motions by very strong muscles, and is but slightly impeded in its free motions by the very shallow socket in which it rests. While this arrangement bestows great freedom of action upon this joint, it renders it liable to dislocation in almost every direction. The most common is that which occurs when the arm is elevated above the head, by means of which the head of the humerus is thrown into the armpit. Next in frequency is the dislocation of the hip joint, which is generally produced by a sudden blow upon the knee when the thigh is flexed toward the abdomen, whereby the head of the thigh bone is drawn backward by the action of the gluteal muscles upon the dorsum of the ileum or pelvis. The jaw bone is often thrown out of place in laughing, and much more frequently in yawning. This accident sometimes occurs while speaking under undue excitement. The writer was cognizant of a case in which a female who was talking in an excited manner, while under the influence of a violent fit of passion, had her discourse suddenly arrested by dislocation of the jaw. This displacement may be easily remedied by placing the thumbs on the back teeth so as to press them downward while the chin is raised by the fingers slowly upward. Care should be taken to remove the thumbs quickly on the restoration of the joint, or they may be painfully compressed between the teeth. —The chief difficulty in restoring a dislocation consists in the opposition offered by the muscles, rendered acutely irritable by the unnatural position of the head of the luxated bone. This is often overcome by reducing the heart's action by general bleeding. The warm bath and emetics are likewise used to relax the muscles, and with the same view tobacco moistened with water is sometimes laid upon the abdomen until it induces sickness and a disposition to syncope. The surgeon in reducing a luxated joint endeavors, by a steady application of force exerted in the direction of the joint, either to fatigue the muscles, or seize some moment when they are relaxed to slip the joint into its socket. Various degrees of force and different appliances

are used to effect this object. In the case of the shoulder joint the surgeon frequently forms a lever with the heel of his boot placed in the armpit, over which, by pressing the arm inward toward the body, he overcomes the resistance of the muscles, and restores the joint. In the case of the hip joint, the force is necessarily great, and pulleys are often resorted to, by which means not only a greater but a steadier force is exerted. A recent dislocation is much more easily reduced than one of long standing; indeed, no time should be permitted to elapse between the accident and an attempt at its reduction, for every hour adds to the uncertainty of the success of the operation. The bones of the spine frequently suffer a partial dislocation which admits of no relief, and not unfrequently terminates in paralysis from the pressure on the spinal column, or death. The hangman in suspending a criminal dislocates the second vertebra of the neck. This sometimes occurs in other ways. A fellow student of the writer, while playing at ball, struck his companion an accidental blow with his club upon the back of the neck, which dislocated this bone and produced almost immediate death.

DISMAL SWAMP, Great, a large morass in Virginia and North Carolina, extending, according to Sir Charles Lyell, 40 m. S. from near Norfolk, in the former state, and 25 m. E. and W. The soil consists of black vegetable matter to the depth of 15 feet, saturated with water, yielding to the tread of man, and during a large part of the year covered in many places with stagnant pools. Several small streams flow through, and in the centre is Lake Drummond, 6 m. long and 3 m. wide, the surface of which is 21 feet above tide water. A large proportion of the swamp was originally covered with a thick forest of cypress, white cedar, and other timber, and portions are overgrown with reeds. Nearly all the most valuable timber has been cut down to furnish shingles, ship timber, and rails, the last being exported to New York and other places, under the name of cedar rails. The shingle trade is enormous, and some of the many proprietors among whom the swamp is divided employ over 100 hands in cutting shingles alone. Since the woods have been thinned out, great quantities of timber have been procured from beneath the surface, where fallen trunks have been preserved by the wetness of the soil. The supply thus obtained, however, is beginning to fail, and the lumber trade of the swamp is losing its importance. The lumbermen are slaves, who are hired of their owners by the proprietors of the swamp lands, and sent into the swamp in gangs, under white overseers. There they remain 5 months out of every 6, camping out in rude huts. An account is kept of the number of shingles cut by each man, for which a fixed sum per 1,000 is allowed, and after the value of the food and clothing furnished, and the hire paid to the owner, have been deducted from the amount, the surplus is given to the slave. The great channel of transportation is the Dismal Swamp canal, made by the assistance of the national government and the state of Virginia, who are the principal owners. It is 6 feet deep, fed by Lake Drummond, and passes for 20 m. through the swamp, affording an outlet not only for lumber but for much of the agricultural produce of the E. part of North Carolina. Its annual freightage was stated in 1856 to be about 24,000,000 shingles, 6,000,000 staves, 165,000 cubic feet of plank, scantling, and ship timber, 700 bbls. of spirits of turpentine, 4,500 bales of cotton, 2,000,000 bushels of Indian corn, 30,000 of wheat, 25,000 of peas, 5,000 cwt. of bacon, 1,300 kegs of lard, 50,000 bbls. of shad and herrings, and 30,000 of naval stores. Roads are made in the swamp by laying logs 8 or 10 feet long side by side on the surface of the soil or "sponge." They are passable by mules and oxen, but carrying is done mostly by hand to the creeks and ditches communicating with the canal. Along the coast of North Carolina are the Little Dismal and several smaller swamps, covering in the aggregate about 2,000,000 acres, and mostly state property. The "Dismals," as they are locally called, are noted retreats of runaway negroes, whose children have been born, lived, and died here. They depend for support on stealing or charity, and chance employment from the lumbermen and poor white settlers. Their number is said to have been much diminished within a few years. A part of the Great Dismal has been drained and devoted to agriculture.

DISPENSATION, the act by which an exception is made to the rigor of the law in favor of some person. To make a dispensation is an attribute of sovereign power. In the United States no power exists, except in the legislature, to dispense with law, and then it is rather a change of the law than a dispensation.—In the Roman Catholic church a dispensation is an exemption from obedience to disciplinary enactments (see Canon Law), and is, more strictly defined, a release from the obligation of observing some ecclesiastical law, granted to a person for just and rational causes, by the proper authority. The pope has reserved to himself the granting of dispensations in the more important cases, but bishops and priests may grant them in lesser ones.

DISRAELI, Benjamin, a British statesman, orator, and novelist, was born in London in December, 1805, and is the eldest son of Isaac Disraeli, the author of the "Curiosities of Literature." His mother's maiden name was Basevi. He received his early education at a private academy in the suburbs of London, whence while yet a boy he was transferred to the office of an attorney as an articled clerk, where he remained 3 years. At length weary of the drudgery of his duties, and with ambitious views far beyond the brightest dreams of the most successful attorney, "Disraeli the Younger," as he loved to style himself, availing himself of the assistance of his father's distinguished friends, obtained admission into what is called in London "the best society." His per-

sonal beauty, refined manners, and remarkable powers of conversation, soon made him a great favorite. At the age of 19 he visited Germany, and on his return to England published in 1826–'7 his famous novel "Vivian Grey," the chief characters in which were faithful pictures of himself and of persons well known in English society. The originality, vivacity, and wit of this book gave it great celebrity, and it was translated into the principal languages of Europe. Simultaneously with its publication the author became editor of a short-lived daily political paper entitled the "Representative," on which John Murray, the publisher, between Jan. 25, 1826, and July 29 following, is said to have expended $350,000. In 1828 Mr. Disraeli published in one volume the "Voyage of Captain Popanilla," a gay and good-humored but flimsy satire, which met with little success. In 1829 he left England to make an extended tour in Italy, Greece, Albania, Syria, Egypt, and Nubia, and returned in 1831. He was in Albania at the time of the massacre of the beys by Reshid Pasha, and witnessed many of the scenes of the civil war then raging there. Shortly after his return he published his second fashionable novel, the "Young Duke;" and in the following year he issued from the press another novel, "Contarini Fleming, a Psychological Autobiography," which Heine the German poet has pronounced to be "one of the most original works ever written." Its subject is the development of the poetical nature, and it contains brilliant sketches of Italy, Spain, Greece, Asia Minor, Syria, and Egypt. At this time Mr. Disraeli made his first attempt to enter parliament. He presented himself to the electors of High Wycombe, in Buckinghamshire, as a tory-radical, and was defeated by the whig candidate. In December, 1834, he again sought the support of the Wycombe electors, and was again defeated. Perceiving that tory-radicalism did not find favor with the English people, he next appeared, in May, 1835, at Taunton, as a thorough-going conservative. It was on this occasion that, when charged by somebody in the crowd with "O'Connellism," he called the great Irish agitator a "bloody traitor;" to which Mr. O'Connell made the memorable retort: "For aught I know, the present Disraeli is the true heir at law of the impenitent thief who died on the cross." Exasperated by this taunt, Mr. Disraeli challenged O'Connell's son, Morgan O'Connell, who had taken up his father's quarrel; but the challenge was not accepted. In the meanwhile Mr. Disraeli wrote and published several books: the "Wondrous Tale of Alroy," an oriental romance of extraordinary eloquence and power, based on the adventures of a prince of the house of David, who in the 12th century proclaimed himself the Messiah, and called the Jews of Persia to arms, appeared in 1833, accompanied by "The Rise of Iskander," a tale founded on the revolt of the famous Scanderbeg against the Turks in the 15th century; a political pamphlet entitled "What Is He?" in 1834, in which he tried to explain his political views; the "Revolutionary Epic" and the "Crisis Examined" in the same year, and "A Vindication of the English Constitution" in 1835. In 1836, being still unable to get a seat in the house of commons, he published a series of letters in the London "Times" under the signature of "Runnymede," which were read with great interest on account of their remarkable wit and sarcasm. Toward the close of the same year he published a love story, "Henrietta Temple;" and in the spring of 1837 appeared "Venetia," a novel, in which he portrayed the characters and appearance of Lord Byron and Percy Bysshe Shelley. At last he achieved the great object of his ambition. In the first parliament of the reign of Victoria, Mr. Disraeli, being then 32 years of age, obtained a seat as representative of the conservative borough of Maidstone. His maiden speech was a lamentable failure. Ignorant of the tastes and temper of his audience, and with the most violent and grotesque gestures, he poured forth the grossest abuse of O'Connell, the only effect of which was to call forth the laughter and ridicule of the house. He closed this now famous speech in the following words: "I am not surprised at the reception I have experienced. I have begun several times many things, and I have often succeeded at last. I shall sit down now; but the time will come when you will hear me." In July, 1839, this prediction first began to be fulfilled. He made a speech which was listened to with attention, and praised for its ability. In that year, too, he published his 5 act tragedy, the "Count Alarcos," founded on an old Spanish ballad, and was relieved from pressing pecuniary difficulties by a marriage with the wealthy widow of Wyndham Lewis, his friend and colleague in the representation of Maidstone. The happy influence of this union upon his career he has himself acknowledged in the graceful dedication of one of his novels to a "perfect wife." In 1841 he was elected as one of the representatives of the borough of Shrewsbury, and in 1844 published his most successful novel, "Coningsby, or the New Generation," which within 3 months of the date of publication had run through 3 editions, and was translated into several foreign languages. The cause of its extraordinary popularity, apart from its great literary merit, was the fact of its principal characters being drawn from well-known persons then living. It was regarded also as an exposition of the views and designs of the famous half literary, half political party then attracting public attention under the name of "Young England," of which Mr. Disraeli was one of the most conspicuous leaders. In 1845 he published "Sibyl, or the Two Nations." In 1847 he was returned as one of the members for Buckinghamshire, and in the same year he published "Ixion in Heaven," with other tales, and also "Tancred, or the New Crusade." His reputation as a parliamentary debater, and as a leading member of the conservative party, was now established. His severe and effective attacks on Sir Robert Peel, for the alleged treachery of

that statesman to his party in the adoption of his free trade policy, are among the most remarkable speeches to be found in the annals of the British legislature. They established Disraeli's reputation as one of the most powerful debaters and keen and polished satirists in that body. In 1849 he became the recognized leader of the conservative party in parliament. A biography of his father, Isaac Disraeli (1849), and a memoir of his personal and political friend, Lord George Bentinck (1852), were his next literary productions. In March, 1852, in the first Derby administration, Mr. Disraeli received the appointment of chancellor of the exchequer, was made a member of the privy council, and became leader of the ministerial party in the house of commons. He went out of office with the rest of the Derby ministry in Dec. of the same year. In Feb. 1858, when Lord Derby again accepted the task of forming a new cabinet after the downfall of Lord Palmerston, Mr. Disraeli was again selected to fill the responsible office, the duties of which he had discharged with great ability 6 years before. In Feb. 1859, he brought forward in parliament an elaborate plan of electoral reform, a principal feature of which was the extension of the suffrage to the whole body of the educated class without regard to property. The bill was defeated in the house of commons, March 31, 1859, whereupon parliament was dissolved. The political career of Mr. Disraeli thus far is one of the most extraordinary in English history. By force of talent, industry, and perseverance, unaided by wealth or family connections, in spite of the disadvantages of his Jewish origin and of his reputation as a mere novelist, he has raised himself to the position of leader of the house of commons and of minister of finance in the greatest commercial empire of the world.

DISRAELI, Isaac, an English author, born near Enfield in May, 1766, died Jan. 19, 1848. His father removed to England in 1748 from Venice, whither his ancestors, of Hebrew race, had fled in the 15th century from the inquisition in Spain. In Venice they assumed the name of Disraeli (originally written D'Israeli), "a name never borne before or since by any other family, that their race might be for ever recognized." Isaac was an only son, and was intended for the pursuits of commerce, by which his father had attained to fortune. The latter was seriously alarmed when his son during his school days produced a poem; "the loss of one of his argosies uninsured could not have filled him with more blank dismay." He was sent to a college at Amsterdam, where he studied the philosophical works in fashion at the time, and when 18 years of age returned to England a disciple of Rousseau. When informed that a place in the establishment of a great merchant was prepared for him, he replied that he had written and intended to publish a poem of considerable length against commerce, which was the corruptor of man; and he at once enclosed his poem to Dr. Johnson, who however was in his last illness and was unable to read it. Of a pensive and sensitive character, fond of solitude and the society of books, he found no literary friend and counsellor, and was sent by his parents, to whom he was an enigma, to travel in France, with the hope that adventures and change of scene might divert him from the eccentricity of his course. He lived in Paris, associating with learned men and frequenting libraries, till 1788. On his return he published anonymously a satire "On the Abuse of Satire," in polished verses, which was directed against Peter Pindar, then in the height of his popularity. This venture obtained for him the friendship of Mr. Pye, afterward poet laureate, through whose influence the elder Disraeli was persuaded to renounce the effort to convert a poet into a merchant, and was finally induced to furnish means sufficient to enable his son to gratify his passion for book-collecting and for tranquil study. The son now wrote some metrical pieces in the magazines, and in 1803 published a volume of romantic tales. In 1791 he published the first volume of his "Curiosities of Literature" (2d vol. in 1793; new edition of both vols. in 1794), a product of curious and elegant erudition, abounding in discursive and anecdotical criticism. A volume of "Miscellanies, or Literary Recreations," was published in 1796. After residing for a time in Exeter he removed to London, and resolved to devote the rest of his life, not to authorship, but to the acquisition of knowledge. Ten years were occupied chiefly with acquiring that store of facts which was the foundation of his future speculations, and it was not till the age of 45 that he resolutely began his career of authorship. In 1812 appeared his "Calamities of Authors; including some Inquiries respecting their Moral and Literary Character;" in 1814, his "Quarrels of Authors; or some Memoirs for our Literary History, including Specimens of Controversy to the Reign of Elizabeth;" and in 1816, the most finished of his compositions, his "Illustrations of the Literary Character; or the History of Men of Genius, drawn from their own Feelings and Confessions." All of these works are amusing and anecdotical, and reveal the author not only as a literary antiquary, but as a man of humor, thoughtfulness, and elegant tastes. His "Curiosities of Literature" had reached the 5th edition, when in 1817 he added a new volume, containing more elaborate essays than the preceding, and the success of the publication was such that he rapidly produced 3 additional volumes. He was 5 years in the composition of his work on the "Life and Reign of Charles I.," which appeared in 1828–'31, and gained for him the degree of D.C.L. from Oxford. He had long meditated a history of English literature, for which all his previous writings had been preparatory, but in 1839 a paralysis of the optic nerve prevented him from pursuing his researches, and a selection from his numerous manuscripts was given to the public in 1841 under the title of "Amenities of Literature." During the latter part of his life he resided on his manor of Bradenham in Buckinghamshire.

"He was," says his son, "a complete literary character, a man who really passed his life in his library. Even marriage produced no change in these habits; he rose to enter the chamber where he lived alone with his books, and at night his lamp was ever lit within the same walls. In London his only amusement was to ramble among booksellers; in the country he scarcely ever left his room but to saunter in abstraction upon a terrace, muse over a chapter, or coin a sentence." A new edition of his works is now in process of publication in London, edited and annotated by his son, the Right Hon. Benjamin Disraeli. His "Curiosities of Literature" was published in Boston in 1858, in 4 vols.

DISSEISIN, a term used in the English law to express the turning a man out of possession of a freehold estate in lands, that is to say, an estate in fee or for life. It is not applied to dispossession of a term of years, nor is it strictly applicable to an incorporal estate, inasmuch as that species of estate does not admit of actual possession in a literal sense; yet constructively there may be disseisin of incorporal rights, as an office, rent, and the like. According to the old common law, disseisin always imported a wrongful putting of another out of possession. An entry by a stranger after the death of the owner of a freehold, and before the heir or devisee had taken possession, was called an abatement; an entry after the determination of a particular estate, before the person entitled to the reversion or remainder, was an intrusion; and an alienation by tenant for life for a longer term than he was entitled to convey was a discontinuance; and different remedies were necessary for the recovery of the possession while the old forms of real actions were in use. As disseisin commenced by a wrongful act of the disseizor, the person disseized could repossess himself by an entry upon the lands; but if the disseizor died in possession, there could be no entry against his heir, but the rightful owner was then put to an action for the recovery of the possession. This rule, however, was subject to certain exceptions, as disability of the person entitled to make the entry; and finally by statute 5 years' possession by the disseizor before his death was necessary in order to take away the right of entry. It was required that the entry should be peaceable, for if force was used a summary process was given by statute to restore the possession to the person thus put out, although, as before supposed, his possession was wrongful, provided he or those from whom he claimed had held the premises 3 years. Possession, although not conclusive evidence of the right of property, was yet deemed of such importance that it could be the subject of an action without involving the question of the real ownership of the fee. The old forms of proceeding by writ of entry, assize of novel disseisin, and the like, were possessory actions. The title to the fee could be determined only by a writ of right or other analogous proceeding. A limitation of time was prescribed for the bringing of possessory actions, which has varied at different periods; but now, by statutes 3 and 4 William IV., c. 27 (1833), no entry can be made nor action brought but within 20 years after the right of entry or action accrued; descent cast (as it was called when the disseizor died in possession) is not allowed to defeat such entry or action, and all the real actions formerly used are abolished, except actions for dower, *quare impedit* (which relates to certain incorporal rights), and ejectment, which last is the mode by which all titles to corporal estates are now tried. In this country, these provisions have been long since generally adopted, and even still greater changes made; and the term disseisin has been little used in American law, and merely as synonymous with dispossession.

DISSENTER, one who differs from another in opinion. It is the general name in England for those Protestants who disagree as to doctrines or ceremonies with the established church. The beginning of dissent in England was in the reign of Edward VI., soon after the establishment of the Anglican church. The two parties were then designated conformists and nonconformists. Subsequently the name of Puritans was for a century the general appellation of dissenters. The legal toleration of dissenters in England dates only from the revolution of 1688, and during the present century they have been placed much more nearly than ever before upon an equality with the adherents of the established church.

DISTAFF, the first instrument employed in spinning, and the ancient emblem of female diligence. It consisted of a staff on one end of which was rolled the wool. It was held in the left hand of the spinner, while the right hand was occupied in drawing out the fibres of the wool, and at the same time twisting them. A small piece of wood called a spindle was attached to the thread, the weight of which continually carried it down as it was formed. When the spindle reached the ground it was unfastened, the thread which had been formed was wound around it, and it was then again fastened near the beginning of the new thread.

DISTEMPER, in painting, a mixture of opaque color with water and size, or with glutinous matter, much used in scene painting.

DISTICH, a couplet, in Greek and Latin poetry consisting of one hexameter and one pentameter verse. The Greeks did not always complete the sense in the two verses, but the Latins imposed this restraint upon themselves. There are numerous ancient poems consisting wholly of distichs, but it required all the art of the best writers to avoid excessive monotony in a kind of poetry which admits of so little variety in the succession of sounds. Its gentle and melancholy rhythm made it a favorite verse of the elegiac poets, and it is in distichs that nearly all the moral precepts of the ancients were dictated.

DISTILLATION (Lat. *dis*, asunder, apart, and *stillare*, to fall in drops), the separating two bodies which may be mixed or combined, by

converting the more volatile one into vapor with the aid of heat, and condensing this product. On heating sea water, the vapor which passes off leaves behind the impurities mechanically mixed, and the salts that were held in chemical solution; the steam condenses upon cold surfaces, and forms drops of pure distilled water. Such is the rain, and such are the dew drops, which in nature's laboratory are distilled from all fluid sources exposed to evaporation, even the most impure. By this process a more volatile liquid may be separated from others less so, as ether, alcohol, or ammonia, &c., from the water with which they may be mixed. The volatile principles of plants, extracted by their solution in water or in other fluids, are thus separated from the substances with which they were associated, and remain with these fluids on their distillation. The vapor of water may itself be made to take up the volatile vegetable principles, as this is evolved in the process of distillation. Vegetable and animal substances undergo a process of destructive distillation by being exposed to the action of heat in close vessels, the effect of which is to separate the volatile fluids and gaseous matters, leaving the solid portions in the retorts. Wood is thus distilled, producing charcoal, tar, the volatile pyroligneous acid, naphtha, &c.; bituminous coal also producing coke, coal tar, ammoniacal liquors, inflammable gases, &c. New combinations of the elements of organic bodies are produced in this process of destructive distillation. When the vapor produced condenses in a solid form, as when sulphur, arsenic, or camphor is volatilized, the operation is called sublimation, and the product a sublimate, as in the other case it is called a distillate. In the chemical laboratory the process of distillation is commonly conducted in vessels called retorts, which are usually of glass. The liquid to be boiled is held in the body of the vessel, and the vapor passes through the neck, which turns over to one side from the top, and connects with another glass vessel called a receiver. This and the neck of the retort being kept cool by the application of cold water upon the outside, the vapors are condensed and collect in the receiver. Glass flasks with bent glass tubes closely fitted in their necks furnish convenient substitutes for retorts. If the supply of vapor is large, more efficient means must be resorted to for its condensation. Such is furnished in the worm of the still, a metallic pipe coiled around within a tub, and kept cool by the water filling the tub, which is removed constantly as it becomes heated, and is replaced by cold water flowing in. The vapors passing through the pipe drop out condensed from its lower end, which projects through the bottom or side of the tub. The still itself is a metallic vessel of any convenient form for a boiler, furnished with a head, which accurately fits upon the body and connects this with the worm or condenser at the other end. For the laboratory metallic stills are little used; the steam produced in the operation of distilling acting upon most metallic surfaces, and the product being rendered impure by the presence of foreign matter thus introduced, the object of distillation, which in chemical operations is to obtain pure products, is thus defeated.

DISTILLERY, works in which the manufacture of ardent spirits is conducted. The operation is commonly called distillation, though this is but the last of several distinct processes involved in the manufacture. The preparation of a highly intoxicating liquor, by separating the more volatile portions of the fermented juices of sweet fruits and infusions of grains, does not appear to have been understood by the ancients. Dr. Ure states that "it seems to have been invented by the barbarians of the north of Europe as a solace to their cold and humid clime; and was first made known to the southern nations in the writings of Arnoldus de Villa Nova and his pupil Raymond Lully, of Majorca." Yet there are but few nations at the present time, above the condition of savages, who are not in the habit of preparing some form of intoxicating liquors by distillation. In the articles Alcohol and Brandy the processes have been explained by which the ardent spirit is produced in the course of fermentation of saccharine juices; and in Beer and Brewing the generation of the same spirit is described as resulting from amylaceous fruits or grains, or those containing starch, by causing this starch to be converted into grape sugar, the fermentation of which produces alcohol. The fermented juice of the grape, or wine, and the fermented infusion of grape sugar derived from malted liquors, contain the same intoxicating principle, which it is the object of distillation to separate; and which, when separated from vegetable substances of such diverse qualities, retains the peculiar aroma or flavor of the plant, until by repeated distillations or rectifications the pure spirit is at last obtained free from the volatile oil and other matters to which the flavor is due. All the juices of plants which can undergo vinous fermentation, and all vegetable matters which contain starch, may thus be made to produce distilled liquors; and many kinds obtained from very cheap and inferior materials are by the introduction of flavoring matters made to pass for those which naturally possess the most esteemed aroma. Some animal fluids also, which contain saccharine matters, may by fermentation produce alcohol. Milk is one of these, and from that of the mare the Tartars manufacture an ardent spirit; the fermented milk is also used by them without distilling. A large proportion of the substances used for the food of man may thus be applied to the preparation of ardent spirit. The fruits of each country furnish spirits of their peculiar flavors, when these are obtained directly from the fermented juice; but if the juices are first allowed to crystallize, the sugar thus obtained, on being redissolved and fermented, is found to have lost the aroma of the plant. Thus the high flavor of the rum distilled from fresh cane juice is missed when the distillation is conducted from fermented sugar and molasses;

the product is then a comparatively insipid whiskey. The distilled liquors of each country are those of its peculiar fruits. Sugar-growing countries produce rum, vine-growing countries brandy, and grain-growing countries whiskey and gin. The Chinese manufacture a distilled liquor from rice, and the inhabitants of Kamtchatka another from mushrooms. The processes of obtaining these liquors are essentially the same, excepting that the grains require some preparatory operations before they are ready like the saccharine juices for immediate fermentation. These operations are in fact the same as those required in brewing. The grain is first subjected to the process of "mashing," and then to that of "cooling," when the infusion is ready for fermentation, after which follows the distillation.—A short account of the manufacture of whiskey as prosecuted in the great distilleries of Scotland will sufficiently explain the various operations. In different establishments the proportions and kind of grain vary considerably. Barley is commonly employed, more or less mixed with oats, rye, or other grains. It may be malted wholly or in part, or may be used with sugar; and sugar and molasses may also answer without grain. Barley malt is the best material, but the heavy duty imposed upon it restricts its use. The effect of the malt is to convert the starch into sugar, as explained in the article DIASTASE, and a small proportion will accomplish this result. If used in the proportion of $\frac{1}{2}$, it is well; but it often forms no more than $\frac{1}{5}$ of the mixture. Dr. Thomson gives an account of the process long conducted with great success in some of the Scotch distilleries, in which 40 bushels of ground barley are mixed with 20 bushels of bruised malt in a mash tun of cast iron, together with about 750 wine gallons of water at the temperature of about 150° F. The mashing is continued by hand labor or machinery for $1\frac{1}{2}$ hours, or longer, with a greater proportion of raw grain. About 500 gallons more of water at 190° to 205° are introduced at intervals to keep up the heat. The whole is then allowed to infuse for 2 hours. During this time the grain subsides, and the liquid above it is a saccharine muddy fluid, called wort. As the starch continues to change into grape sugar by the action of the diastase in the malt, the sweetness of this fluid increases. After the infusion the greater part, usually $\frac{2}{3}$, of the wort is drawn off from the top. In brewing, the whole contents are drawn off together from the bottom. The infusion upon the same grain is then renewed with 500 gallons more of water at 190°, and continued another hour and a half; and a third infusion after the wort has been drawn off succeeds this with 800 gallons of boiling water. This being well stirred for 20 minutes and then left for about half an hour, the saccharine matters are found to be extracted from the grain; the wort is drawn off, and is either boiled down to bring it to the required strength, or is added to the 1st and 2d worts, or is kept to be used instead of pure water for the first infusion of the next mashing. Strong worts are not desirable, the fermentation being more complete and the yield of spirits greater when these are of moderate specific gravity. By the old excise laws of Great Britain they were required to be of a certain high degree of strength, but in Scotland and Ireland they are now allowed to range from specific gravity 1030 to 1080, that of water being 1000. The next process is that of cooling the worts, and in consequence of the tendency of those produced from raw grain to become acid, this must be rapidly accomplished. In some distilleries the liquors are run into large shallow coolers, placed in an exposed situation in the upper part of the building, and filled only a few inches deep; and artificial arrangements are made for producing currents of air over the surface. In others, which are supplied with abundance of cold water, the worts are passed through tin or copper pipes surrounded with this cooling medium. When reduced in cold weather (which is the most suitable for this business) to a temperature between 52° and 65°, the worts are transferred, together with the starchy matter which subsides in the cooling, to the fermenting tuns. In the improved process of rapid fermentation now adopted, the worts are more commonly of the temperature of from 65° to 76°, and the process, instead of being conducted as formerly by adding at intervals of each day quantities of brewer's yeast for 4 or 5 days and protracting the operation through a period of about 10 days, is completed in 2 or 3 days. The yeast is added at once, a gallon or a gallon and a half, according to the season, to each 100 gallons of wort; and if the fermentation does not go on briskly enough, more is added the next day. Upon the quality of the yeast the success of the important process of fermentation in great measure depends. The object is to decompose the largest possible proportion of the saccharine matter, and convert it into alcohol; but the presence of the alcohol as it is formed impedes the progress of this change, and a quantity often amounting to $\frac{1}{3}$ of the whole saccharine matter escapes decomposition; in strong worts this proportion is greater than in weak worts. By the invention of Mr. Sheridan in fermenting the wash in close tuns, and causing the alcohol to evaporate by using a powerful air pump, the whole saccharine matter was alcoholized, but the excise restrictions prevented the adoption of this improvement. As the process goes on the fluid becomes of less specific gravity, and when successfully conducted its density is found to be the same as that of water. If it be pushed too far, or go on sluggishly or at too high a temperature, loss will result by a portion of the alcohol passing to acetic acid, the presence of which is indicated by increase of specific gravity, as well as by its peculiar odor and taste. The undecomposed portion of the wort, or, as it is called after fermentation, the wash, is a loss to the distiller, the only use made of it being to feed cattle and swine, for which its

sweetness renders it a fattening material. The fermenting tuns are huge vats of wood or iron, and when of the latter material are so constructed that hot or cold water may be applied to the outside to regulate the temperature of the contents. The operation as it goes on is thus described by Dr. Thomson in the "Records of General Science," vol. ii.: "Its first effects are indicated round the sides of the back (tun) by the appearance of a scummy-looking matter on the surface of the worts, and the emission of small bubbles, which contain carbonic acid gas. The temperature increases as fermentation advances; its progress is rather slow at first, but gradually increases, and after some time proceeds with prodigious rapidity. Large bubbles of carbonic acid gas escaping set the whole in motion, as if in a state of violent ebullition; a large quantity of froth collects on the surface of the liquor (which is now called wash), which often accumulates with such rapidity that several men are required to beat it down with oars, to prevent its spilling over the top; indeed, on some occasions, the beating on the top has been found ineffectual, and the distiller forced to pump a portion of the wash up to the coolers to lower its temperature, and then return it, after which the process proceeded at a moderate rate; and in all cases, toward its close, the rate of fermentation gradually diminishes, and the temperature decreases, till at last the wash acquires the temperature of the tun room, and remains quiescent."—The process of distillation, which, by distinguishing the preparation of ardent spirits from that of fermented liquors, gives its name to the whole operation, now succeeds. It is conducted in stills of various sizes and forms, some of which in the largest establishments have a capacity equal to distilling 2,000 gallons of wash per hour; one at Leith is described as exceeding even this by more than ½. As formerly constructed, this apparatus was made large, but of such depth that its contents were evaporated only once in a whole week. Duties in Scotland being imposed upon the works, based on the dimensions of the stills, led the distillers to enlarge the size of the bottoms exposed to the fire, by which the time of the operation was reduced to a few hours. As the duty was subsequently increased, but still based on the same principle, the distillers contrived to increase the production of the stills without enlarging them, until by working them rapidly, with great consumption of fuel, one of the capacity of 80 gallons could be completely distilled off, emptied, and ready for a new operation, in 3½ minutes, and in some cases in 3 minutes, and one of 40 gallons in 2½ minutes. In 1815 this mode of assessing the duties was abolished; but the large diameter of the bottoms of the stills is retained, and the operations are more rapidly conducted than elsewhere.—In distilling a mixture of liquids, as alcohol and water, the boiling points of which are not the same, the more volatile fluid, as the former in this instance, begins to be converted into vapor near the mean temperature between the 2 boiling points, which is about 190°, alcohol boiling at 170° and water at 212°. As the proportion of alcohol diminishes by reason of its forming the principal portion of the first products of the distillation, the boiling point of the mixture becomes higher, till it approaches that of water. The process is then stopped, aqueous vapor forming the principal part of the product. The liquor which remains in the still is let off, and is of no further value but to feed cattle. In condensing the products of the distillation, the same law is observed of the alcohol and water reassuming the liquid state, which regulated their leaving it. Whenever the vapors are cooled below 212°, the aqueous portion condenses; but the greater part of the alcoholic vapors remains uncondensed till their temperature falls below their boiling point. By keeping up the heat, and gradually diminishing it through a series of condensing vessels, similar to the apparatus called the Woulfe bottles, used in chemical laboratories for impregnating liquids with gases, the products may be in great part separated from each other, those furthest off from the still receiving the most volatile or the most alcoholic vapors, while the water is arrested in those of higher temperature into which the vapors are first received. Some volatile oils also, which are produced with the alcohol and communicate to it an unpleasant flavor, are more readily condensed than this, and are consequently detained and got rid of together with the aqueous portion of the mixture. It is on this principle that the great improvements have been introduced in the modern stills, the old form of the worm having the great imperfection of letting the vapors all condense and run together into one receiver. The idea of this application was suggested in the year 1801 to a Frenchman, Édouard Adam, who is described as an uneducated man, a distiller by trade, though ignorant of the art. He saw the Woulfe apparatus at a chemical lecture which he attended at Montpellier, and soon constructed a similar arrangement for condensing brandy distilled from wine. This succeeded so well that the whole process of distillation was soon completely changed. The restrictions of the excise laws of Great Britain prevented the introduction of the improvement into that country until after their modification in 1815. Adam's apparatus was in the mean time much improved in France by the inventions of Isaac Bérard, Blumenthal, and Derosne, by which the process was made continuous, the wine being supplied at one place, and, when deprived of its alcohol, escaping at another in a continued stream. The portions first condensed, least rich in alcohol, were made to flow back into the still by pipes arranged for the purpose. In England the same form of still has been greatly improved to adapt it to the immense scale upon which the operations are there conducted. The most efficient apparatus of this kind for the production of grain whiskey is that invented by Mr. Coffee

of Dublin, and for the production of malt whiskey that of Stein, which is based upon the same principle, but is intended to retain the volatile oils which impart flavor to the spirits. They are too complicated for any intelligible description to be given of them without drawings. They work continuously; that is, so long as the operation is kept up new wash continues to be supplied. The wash, already heated before it enters the apparatus, is exposed in a series of shallow chambers to currents of steam which take up the alcoholic vapors and carry them into the condensing part of the apparatus. This consists of a series of chambers, which are successively colder as their distance increases from the entering point of the hot vapors. They collect the condensed fluid of all degrees of strength and of the utmost purity. The strongest commercial spirits of wine are thus produced by a single operation, rendering the old processes of rectification quite unnecessary. But in producing these strong spirits the flavor is lost, and the product is consequently not a favorite with whiskey drinkers. It is, however, often made to suit their taste by dilution with water and flavoring "with a dose of the most odorous malt spirit." Such is said to be the mode of manufacturing the greater part of the so-called malt whiskey, and nearly all the Scotch whiskey sold in England. The economy of Coffee's still is very striking. "The water for supplying the boiler passes through a long coil of pipe immersed in the boiling hot spent wash, by which means it is raised to a high temperature before it reaches the boiler. The vapor which passes through this apparatus is all condensed by the wash, not by the water, so that no heat is wasted. It is stated that about ¾ of the fuel used with the common stills is saved by this apparatus. By the usual process, to distil a gallon of proof spirits 12 lbs. of coal are required, 9 lbs. of which are saved by this apparatus. Supposing the whole quantity of spirits distilled in Great Britain and Ireland to be 36,000,000 gallons, and that the improved still is adopted, the saving of fuel would amount to 140,000 tons of coal per annum."—The products of the distilleries of different localities are distinguished by peculiar flavors, which give a reputation to their liquors. These have for the most part little to do with the original qualities of the materials from which the ardent spirits are obtained, but are commonly derived from the fuel burned in drying the malt. Much of the Scotch highland and Irish whiskey possesses a peculiar flavor of peat smoke, possibly derived from the bog water in which the malt is steeped; other qualities have a birch oil or Russia leather flavor from the use of birch for fuel. Brandies manufactured from wines have their peculiar flavors from the distillation being conducted at sufficiently high temperature to carry over the volatile oils, some acetic acid, acetic ether, and other matters, and these are retained together with so much water that their strength is considerably below that of the ardent spirits produced in Great Britain; they commonly consist of more than half water. Gin, known also by the names Schiedam, Hollands, and Geneva, has long been manufactured at Schiedam in Holland, by the same process at the different distilleries. The materials are 112 lbs. of barley malt (weight about 37 lbs. to the bushel) and 228 lbs. of rye meal mashed with 460 gallons of water at 162°. After infusing, cold water is added till the strength is reduced to 45 lbs. per barrel, of specific gravity 1.047. At the temperature of 80° it is run into the fermenting tubs, and half a gallon of good yeast is added for every 500 gallons of liquor. The temperature rises to 90°, and in 48 hours the attenuation is complete. From 12 to 15 lbs. of undecomposed saccharine matter still remain in the liquor. Both the wash and grains are put into the still, and the whole of the low wines are distilled off. These are again distilled, and after rectification, in which juniper berries and sometimes hops are added to give the flavor, the product is the famous Geneva. The process is peculiar in the fermentation not being prosecuted to the usual extent, and in the small quantity of yeast added to promote it. Gin manufactured in England, and rum also, is whiskey disguised with suitable flavorings.—In France several distilleries are engaged in manufacturing ardent spirits from potatoes, both by fermenting the steamed and mashed potato, and by treating the starch previously prepared from the tuber with sulphuric acid, thus converting it into sugar. The advantages of the process are said to be the cheapness of the material, the excellence of the spirit, the saving of the more valuable grains for other uses, and the economy in yeast. The residuum of the process is also good food for cattle. It is found that 110.3 lbs. avoirdupois of potato starch produce from 4.4 to 5.5 imperial gallons of alcohol at 0.935. From some experiments of Dr. Hare upon sweet potatoes, it would appear that they are as well adapted as malt for the manufacture of ale, and so probably for ardent spirits. Five bushels of potatoes are thought to produce as much wort as 3 of malt, and the residue to be worth half the cost of the potatoes as food for cattle. Carrots also have produced liquor of good quality and a residue making excellent feed for stock. The molasses of beet sugar factories is used for the same purpose. The manufacture of spirit from the washings of madder, which have heretofore been allowed to run to waste in the dyeing establishments, is now carried on at several distilleries in France and at one in Glasgow. Two tons of madder liquor at 30° are stated to produce about 60 gallons of spirit. In the north of France the berries of the mountain ash, *sorbus aucuparia*, are made to produce brandy equal, it is said, to the best made from wine. The second distillation is from the first distillate mixed with very fresh and finely powdered charcoal in the proportion of 8 or 9 lbs. to every 40 gallons of weak spirit. Charcoal coarsely ground is used in many of the distilleries of the United States as a filter for purifying whiskey.

—All the spirits obtained from these various sources are but mixtures of alcohol and water, disguised by the peculiar flavors of the principal materials employed, or of those incidentally introduced, as the yeast, soap thrown into the stills to check, by the oily scum it produces, a boiling over of the liquors, or the peat, &c. These flavors are removed by the process of rectification, which succeeds that of the distillation proper, and in England is commonly but not always conducted at a separate establishment. It involves further distillations from substances introduced into the spirits, which combine with the essential oils and other noxious ingredients and render them fixed, while the alcoholic portions are distilled over. The crudest spirits of whatever origin, contaminated with the unwholesome fusel oil, or the disagreeable yeast, are thus brought to the same degree of purity with the choicest products of distillation, and then by the art of the rectifying distiller are converted into imitations of any genuine liquors or cordials, and sold as such. A great number of substances are employed for purifying the liquors; caustic potassa, under the name of gray salts, and pearl ash, called white salts, are commonly used in the proportion of 4 lbs. of each to every 700 gallons of crude spirits. Charcoal and ashes are also employed, the latter to neutralize any acid present.—The total revenue of Great Britain from spirits for the year ending Jan. 5, 1854, was £6,760,422 6*s.* 6*d.*—The distilleries of the United States, though no doubt far more extensive than the good of the people requires, are much behind those of Great Britain in the perfection of their machinery and the wonderful capacity of production of single establishments. Whiskey from rye and Indian corn is the product of American distilleries; rum, manufactured from West India molasses, is produced to a limited extent, and brandy is made from some of the fruits upon a very small scale. The manufacture of whiskey is conducted in a great number of small distilleries along the seaboard, and large quantities of the raw liquor are exported to France to be there rectified and converted into French brandy. The distilleries of the western states, particularly of Ohio and western Pennsylvania, produce immense quantities of whiskey, which are sent down the rivers to find a market in New Orleans, whence they are largely exported.

DISTRESS (Lat. *distringo*, to press, straighten, wring out), a term applied to the taking of property of a tenant for non-payment of rent; also to the seizing of cattle for damage done by them; and lastly to a proceeding for the coercion of a defendant to appear in a cause after service of the summons by which an action was at an ancient period commenced. In the two cases first mentioned, the landlord or person who had been injured could make the seizure himself or by his deputy—an anomalous authority, entirely at variance with a fundamental principle of law that parties should not be permitted to redress their own injuries without judicial process. The reception of property which has been wrongfully taken away, or wrongfully detained, or the reëntry upon lands of which a man has been dispossessed, though analogous in one respect to distress for rent or *damage feasant*, yet differ in another, viz.: that such reception or reëntry cannot be made with force, whereas a distress may be executed in like manner as process upon a judgment, that is to say, force may be used in case of resistance. The 3d case above mentioned, viz., distress to compel an appearance, was by a judicial writ called a *distringas*, which it will be unnecessary to consider further under this head, as it belongs more properly to the practice of courts. In a popular sense, a distress is understood only of the taking property of a tenant or wrong doer in satisfaction of rent or damages, and to this we shall limit our remarks in the residue of this article. The term is with some incongruity applied as well to the property taken as to the act of taking. Formerly, the property distrained was deemed a mere pledge, and the distrainor had no power over it except that of detaining it till satisfaction of the rent or damages for which the distress was made; but for the security of the owner it was required that the property should be kept in a pound (*parcus*, which signifies any enclosure); and if the distress consisted of live animals, it was required that they should be impounded within 3 miles of the place where they were taken. If put into a public pound, the risk and expense of keeping the same devolved upon the owner without notice from the distrainor. By statute 11 George II., c. 19, the distrainor was authorized to make a special pound upon the premises where the distress was taken, in which case notice to the owner was required; but the liability to provide necessaries for animals belonged to the owner as in the other case. The distrainor was bound to keep a distress of chattels which might be injured by exposure to the weather in a pound covert. A distress was allowed only by daylight, except in the case of beasts *damage feasant*, which might be taken at night, lest they should escape. Formerly the landlord could distrain only such goods as were found upon the premises for which rent was due, but by statute goods which have been clandestinely removed may be followed within 30 days after the rent accrues. In making the distress the landlord is not permitted to break open the outer door of the house, but being once in, he can break an inner door, being the same rule as in levy upon execution. As to the amount of distress, the only protection of the tenant is by an ancient statute (52 Henry III., c. 4) under which an action may be brought for the taking of an unreasonable or excessive amount. After the impounding of the property, by the ancient law the remedy of the distrainor ceased; but by various modern statutes, when the distress is for rent, it may be sold after the expiration of 5 days for payment of the rent. Such is the present law of England in respect to dis-

tresses. In the United States important modifications have been made. In the state of New York, distress for rent was abolished in 1846; it is still, however, allowed for injuries done by animals, but provision has been made for a sale of such animals in satisfaction of damages and expenses, in like manner as provided in England respecting a distress for rent.

DISTRICT OF COLUMBIA, a tract of territory containing the seat of government of the United States, and subject to the exclusive jurisdiction of congress. It is about 300 miles from the ocean by the Potomac river and Chesapeake bay, and lies between lat. 38° 51′ and 39° N., and long. 76° 58′ and 77° 06′ W. It was named in honor of Christopher Columbus, and also with some reference to the poetical use of the term Columbia as a designation for the United States. It is bounded on the S. W. by the Potomac, and on all other sides by Maryland, and is 10 m. long from N. W. to S. E., with an area of about 60 sq. m. It forms the county of Washington, and contains 2 cities, Washington and Georgetown. The greater part of the area is outside the boundaries of these cities. The surface is undulating, with hills sufficiently high to command extensive views and afford fine sites for public edifices. The soil is light and moderately fertile. The agricultural products comprise wheat, rye, Indian corn, oats, barley, buckwheat, peas, beans, Irish and sweet potatoes, hops, and tobacco. A few hundred gallons of wine are made annually. Two considerable streams empty into the Potomac within the district, Rock creek, and the Anacostia or Eastern branch. There are also several small brooks, to one of which the name of the Tiber was given by the early settlers in the 17th century, because a planter named Pope lived near it. The climate is moist and warm, and there is much local miasma. In the summer and autumn fevers prevail in many parts, especially in the low grounds near the Potomac. The population of the district by the census of 1850 was 51,687, of whom 37,941 were whites, 10,059 free colored, and 3,687 slaves. At present (1859) the population is estimated at 65,000. The commerce of the district is very small, and is carried on chiefly through Georgetown. The value of exports to foreign countries in the year ending June 30, 1858, amounted to $16,710; of imports, $26,520. The shipping owned within the district amounted to 33,974 tons, of which 656 tons was registered, and the remainder employed in the coasting trade and the Chesapeake and Ohio canal. The steam shipping amounted to 3,971 tons. The Chesapeake and Ohio canal passes through a portion of the district, and crossing the Potomac at Georgetown terminates at Alexandria. A branch of the Baltimore and Ohio railroad terminates in Washington, and a railroad connects Washington with Alexandria. There are 2 colleges in the district, Georgetown college and Columbian college. The former is under the direction of the Jesuits, and was founded as an academy in 1789 and chartered as a college in 1792. In 1818 congress gave it authority to confer degrees. It occupies 2 brick buildings in the western part of Georgetown, and owns a large and valuable tract of land. It has a museum of natural history, an extensive philosophical apparatus, and a botanic garden. Connected with it is a flourishing female seminary taught by nuns. In 1858 this college had 21 instructors, 245 students, and 26,000 volumes in its libraries. Columbian college stands in a plot of 46 acres just outside the northern boundary of Washington city. It was founded in 1821 under the auspices of the Baptist general convention. It occupies a building 117 feet by 47, 4 stories high, and costing $35,000. The funds contributed to the college since its foundation amount to $187,000. It has a library of 7,500 volumes and property estimated at $170,000. In 1858 there were 8 professors and 66 students. From a census taken by a committee of the Columbian teachers' association in Dec. 1857, it appears that only about one half of the white children in the district are receiving school education. Of 10,697 children in Washington city between the ages of 5 and 18, 5,069 were not attending any school.—After the adoption of the articles of confederation by the United States, the question of fixing upon a seat of government for the Union excited great interest, and called forth much sectional rivalry. During the period between the conclusion of the revolutionary war and the adoption of the present constitution, congress met alternately at Princeton, Annapolis, Trenton, and New York. After the organization of the government under the constitution on March 3, 1789, warm discussions took place in congress on the location of the capital, which were finally settled by the passage, June 28, 1790, of an act containing the following clause: "That a district of territory on the river Potomac, at some place between the mouths of the Eastern branch and the Connogacheague, be, and the same is hereby accepted for the permanent seat of the government of the United States." The same act provided that congress should hold its sessions at Philadelphia until the 1st Monday in November, 1800, when the government should remove to the district selected on the Potomac. The area fixed upon for the district was a square of 10 miles, or 100 square miles. It embraced about 60 square miles of Maryland, which was ceded by that state to the United States in 1788, and 40 square miles of Virginia, ceded in 1789. The portion on the Virginia side of the Potomac was retroceded to that state in 1846. The constitution of the United States confers upon congress the exclusive legislative control over the district, but does not allow the inhabitants any representation, or any vote for national officers. The district is governed by laws enacted by congress and by the laws of Maryland in force at the time of the cession to the United States. A code of laws prepared by commissioners under the sanction of congress was submitted to the people in 1858 and rejected by a decisive vote. The official expenses of the district are

paid by the federal government. The following table shows the amount expended by the United States for improvements in the district up to June 30, 1857:

Years.	For the gov't.	For the district.
1800–'48	$6,530,814 42	$2,708,253 88
1848–'49	63,045 99	189,000 00
1849–'50	69,945 01	195,126 03
1850–'51	157,370 78	279,901 08
1851–'52	403,265 69	158,869 03
1852–'53	882,223 05	154,630 03
1853–'54	429,884 03	954,910 81
1854–'55	1,074,749 65	129,165 58
1855–'56	1,278,230 35	200,495 26
1856–'57	1,859,313 36	250,073 77
Total	$12,748,842 33	$5,120,435 47

(See Georgetown and Washington.)

DITHYRAMBUS, in Grecian antiquity, a song sung in the vintage season in honor of Bacchus. The origin of these songs is traced to the earliest ages of Greek civilization, and the most famed of the early composers of them was Arion of Methymna. But few fragments of ancient dithyrambic poetry remain, and it is only by tradition that we know the successes of Melanippides, Pindar, and Philoxenus, in this style of composition. The character of the dithyrambus was primitively religious, it being designed for showing gratitude to the deity; and it was lively, rapid, brilliant, and disordered, like the joy and intoxication of a Bacchanalian festival. In the heat of improvisation, the poets allowed themselves to unite several words into one, from which there resulted expressions so voluminous and sonorous that they wearied alike the ear and imagination. The Latins had the good taste not to borrow from the Greeks this kind of poetry, which in the age of Pericles was the object of the railleries even of the Athenians. A parody of Aristophanes informs us that the extravagance of the dithyrambic poets had in his time become proverbial.

DITMARSH, Ditmarsch, Ditmarshes, Dithmarsh, Dithmarschen, or Ditmarsen, the westernmost division of the duchy of Holstein, Denmark, bounded N. by the Eider river, W. by the Wilstermarsh, S. by the Elbe, and E. by the German ocean; area, 500 sq. m.; pop. in 1855, 61,388. Consisting almost wholly of low marshes protected against the sea by dikes, it is better suited for cattle-raising than for agriculture. But its chief importance is historical and ethnological. The inhabitants, supposed by some to be descendants of the old Marsi, have preserved all prominent features of the primitive Teutonic character in the most marked form, and may in some respects be called a relic of the specific German culture of the earliest times. Through all vicissitudes of time they have faithfully clung to their ancient institutions of municipal self-government, equality of all freeholders (there never has been a nobility among them), and many peculiar social customs, the origin of which dates back to a time before the Germans were converted to Christianity. They are a hardy and tough race, and in their struggles to maintain their independence they have shown great devotion, courage, and persistency. Yet they have not always acted on the defensive. There was a time in their history when they frequently emerged from their inaccessible marshes like the old Northmen, in order to subject the neighboring tribes. From the 6th to the 9th century Ditmarsh was a portion of northern Albrigia. In 921 the country was given in fief by the German emperor to the counts of Stade. In 1072 it was conquered by the duke of Mecklenburg, Kruko, but after his death the counts of Stade ruled it once more. The tyranny of some of these drove the inhabitants to open rebellion, and they slew their oppressors. In consequence, Henry the Lion, duke of Saxony and Bavaria, invaded their country and chastised them severely, but after his death the emperor united the territory with the bishopric of Bremen. They improved this opportunity to drive all knights and noblemen from among them. Near the end of the 12th century they subjected themselves voluntarily to Danish rule, but threw off their allegiance in 1227. From that time they were almost constantly in feud with the dukes of Holstein and kings of Denmark, who for 3 centuries were unable to obtain a firm foothold in their country, while on the contrary the Ditmarshers very frequently invaded the Danish territory. In 1500 King John of Denmark, with an army of 30,000 men, marched into Ditmarsh, took the town of Meldorf, and butchered all the inhabitants, without distinction of age or sex. Then it was that the sturdy peasants, led by one of their number, Wolf Iseband, intrusted their banner to a maiden, Else of Oldenwoerde, and after a hotly contested battle, opened the sluices of the dikes, thus inundating the whole country, and drowning some 20,000 Danes. For 60 years after this victory Ditmarsh enjoyed perfect independence; but in 1559 Frederic II. of Denmark conquered it, after a manful resistance. Since that time Ditmarsh has been a portion of Holstein, but it has always been treated as a quasi independent territory, and its administration is directed by a special code of laws, dating back to the year 1321.

DITTON, Humphrey, an English mathematician, born in Salisbury, May 29, 1675, died Oct. 15, 1715. He received an excellent private education, and it was doubtless owing to the nonconformist principles of his parents that he studied at neither of the universities. At his father's solicitation he studied theology, and filled for several years the functions of a minister at Tunbridge, in Kent. Upon the death of his father he relinquished the clerical profession, and devoted himself to the more congenial study of mathematics. He was encouraged by Sir Isaac Newton, through whose influence he was elected professor in the newly created mathematical school of Christ's hospital, a position which he retained till his death. In 1714 he published, with Whiston, an advertisement of a new method of finding the longitude at sea. The plan was approved by Newton, but rejected by the board of longitude; and it is said that the chagrin caused by this disappointment, and by

some sarcastic verses of Dean Swift, occasioned the premature death of Ditton. He was the author of numerous mathematical treatises, among which are the following: "Of the Tangents of Curves;" "General Laws of Nature and of Motion;" an "Institution of Fluxions;" and the "New Law of Fluids, or a Discourse concerning the Ascent of Liquids in exact Geometrical Figures, between two nearly contiguous Surfaces." His writings upon theology are the least of his titles to fame.

DIU, an island of Hindostan, belonging to the Portuguese, formerly a fortified place of great trade. It lies south of Guzerat, from which it is separated by a narrow channel, in lat. 20° 42′ N., long. 70° 52′ E. It is about 1½ m. in breadth, and stretches parallel to the coast for a distance of 7 m. The Portuguese took possession of Diu in 1535, and immediately provided it with strong fortifications. It had an important commerce until the decline of the Portuguese power, but was taken and plundered by the Muscat Arabs in 1670, and has never recovered its prosperity. The town of Diu lies on the east end of the island, and has a population of 4,000. The island is generallly unfit for cultivation, and its water is brackish; but provisions are plentifully supplied from the mainland, and water is secured in reservoirs during the rainy season.

DIVAN, an oriental word found in the Arabic, Turkish, and Persian languages, and applied in the East to every seat of authority, to the place where the sultan, the minister, the governor, the bey, the pasha, or the dey pronounces his orders, receives communications, and conducts his administration. It designates not only the official habitation, the chamber of a functionary, but also the series of cushions and couches ranged along the walls which serve as the seats of all subordinate officers.—In literature, divan designates among the Persians and Turks a collection of songs. A complete divan contains as many poems as there are letters in the alphabet, and each poem rhymes throughout, every line terminating with the same letter, which is different in the different poems. Goethe collected some of his minor poems under the title of divan.

DIVER (*colymbus*, Linn.), a bird of the order *anseres*, and family *colymbidæ*, the latter containing the divers and the grebes. The bill in this genus is long, strong, straight, curved slightly at the tip, which is sharp, with compressed sides; the nostrils are in a membranous groove; the wings are moderate and pointed, the first and second quills the longest; the tail is very short and rounded; the tarsi rather short, compressed, and covered with reticulated scales; the toes long, the 3 anterior united by an entire web, and the inner side of the internal toe margined with membrane; the hind toe short, with a small membranous margin; the claws moderate, depressed, and broad. Only 3 species are well ascertained, the *C. glacialis*, *C. arcticus*, and *C. septentrionalis* (Linn.), which belong to the arctic circle, migrating to the northern temperate regions of America and Europe. The great northern diver, generally called loon in the United States (*C. glacialis*), is a large, powerful, and handsome bird; the largest males measure about 3 feet to the end of tail, with an extent of wings of nearly 5 feet, and a weight of from 8 to 10 lbs. The head is moderate, narrowed in front; the neck thick and long; the body elongated and depressed; the feet very far back; the plumage is short and dense. The bill is black, iris deep bright red, feet of a grayish blue, with the webs brownish black; the head and neck are dark greenish blue, with purple reflections; on the throat there is a transverse white patch, with longitudinal dusky streaks; in the middle of the neck are 2 white patches, continuous behind, but separated an inch in front; the sides of the neck at the lower part are streaked longitudinally black and white, there being on each feather 2 oblong spots of the latter hue; the upper parts are glossy black, with spots of white in regular transverse curved lines with the convexity backward, the spots being rounded and small toward the neck, sides, and tail coverts, larger and quadrangular on the middle of the back, largest on the scapulars; the lower parts are white, except on the sides under the wing, which are black with elliptical white spots, a faint dusky band across the vent, and the lower tail coverts, which are blackish, tipped with white; the tail is brownish black, with a paler tip. The female resembles the male in colors, but is smaller in size. The young in winter are dark grayish brown above, white underneath, with the sides dusky; toward spring the white spots begin to appear, and the plumage is that of the adult at the end of summer; they go further south than the adults. The flight is rapid, long sustained, and at a considerable elevation. The gait of the bird on land is generally slow and awkward; on the water, when at ease, it swims lightly, but when alarmed it sinks the body so deeply that not more than an inch of its back can be seen. As a diver it is unsurpassed except by the darter and the auk, disappearing quickly, flying rapidly beneath the surface, remaining under water a long time, and coming up again at a great distance from the spot of its disappearance. Loons are occasionally found drowned in fishermen's nets, and are sometimes caught on hooks. The curiosity of the loon is often taken advantage of to draw them within shot, as the bird will almost always approach any bright colored object waved by a concealed gunner. Its notes are so loud and plaintive that to be "as noisy as a loon" has become a proverb. Its food consists of fish, lizards, frogs, aquatic insects, and the roots of fresh-water plants; it fishes in both salt and fresh water, and usually swallows its food beneath the surface. Though the flesh is tough and rank, it is occasionally used as food. The loon breeds in various parts of the United States from Maine to Maryland, according to Audubon, and Dr. Richardson states that it is found breeding as

far as 70° N. The nest is built near the water, in marshes, on the ground, and of rushes and grasses growing in the vicinity. The eggs are generally 3, about 3¾ inches long by 2¼ broad, elongated, with a narrow point; their color is dull greenish ochry, with indistinct spots of dark umber, most numerous toward the larger end. The geographical range of the loon is very extensive, from the Atlantic to the Pacific, and from the fur countries to Florida; it is found also in Europe and northern Asia. The black-throated diver (*C. arcticus*), next in size to the loon, is 29 inches long to the end of tail, with an extent of wings of about 40 inches. The upper parts are glossy black, with a greenish tinge anteriorly and brownish behind, the head and hind neck being hoary; on the fore part of the back are 2 longitudinal bands of white bars, the feathers tipped with white; the scapulars and wing coverts with white spots; the quills are blackish brown, with a gray tinge externally; on the front of the neck for about 6 inches is a purplish black patch, ending angularly below, with a band of white spots above; the sides of the neck are blackish brown, with longitudinal white streaks; the lower parts are pure white, except a dusky band under the wings. The female is smaller than the male, but similarly colored. This species breeds in the far north, where the old birds principally remain, and whence the young wander over North America and northern and eastern Europe. Birds in full plumage are rarely obtained in the United States, and, according to Audubon, never further south than Delaware; along the eastern shores they are seen from autumn until spring. Their flight is rapid and well sustained, and performed with the neck and feet stretched out at full length. The red-throated diver (*C. septentrionalis*) is about 26 inches long, with an extent of wing of 43 inches, and a weight of 4 lbs. It resembles the preceding species except in the rich brownish red color of the anterior neck, and the lines of black and white on the hind head and neck; in the young males the fore neck is merely dotted with red. They begin to fly north to breed from early spring to the middle of May; they are found on the coast from Maryland to Maine, from autumn to spring; the younger the birds, the further south they go, and it is rare to find an old one south of Boston; they abound in the bay of Fundy. They are very shy, and always approach their nests from the water. Both sexes incubate. The full beauty of the plumage is not attained until the 4th year. They are rarely seen inland, and almost never out of the breeding season. Along the New England coast and in the bay of Fundy they are commonly called "cape-racer" and "scapegrace."

DIVI, or Divi-Divi, the pod of a leguminous shrub, *cæsalpinia coriaria*, a native of the northern parts of South America and the West India islands, used for tanning, for which purpose it is exported to Europe and other countries. The plant grows to the height of 20 or 30 feet, and the pods, which are of a dark brown color, and curl up in drying, attain a length of 3 inches. The rind has a strongly astringent and bitter taste from the tannin contained between the outer layer and the husk that encloses the seed. The leather prepared with it is very porous, and acquires a deep brownish red color. The astringent property of the pod recommends it as a mordant in dyeing, and it is used to some extent for this purpose instead of sumach. Almost the only ports of shipment are Maracaibo, Rio Hacha, and Savanilla. The exportations to various parts of Great Britain, principally to Liverpool, in 1856, were 4,186 tons.

DIVIDING ENGINE. Instruments for astronomical or geodetical purposes were formerly divided by hand, and but few artists possessed the faculty of dividing them, so that even good instruments for the common purposes of navigation were difficult to be obtained. Mr. Jesse Ramsden, a cloth presser by trade, who subsequently turned his attention to engraving, being brought in contact with mathematical instrument makers, was led to construct the engine which for many years was called by his name. At that time (1775) it was considered so valuable that the commissioners of longitude entered into a contract with him to instruct a certain number of persons, not exceeding 10, in the method of making and using it, and to divide sextants and octants at certain prices as long as the engine remained in his possession, they becoming the purchasers for the sum of £315, and giving £300 in addition for the invention. Perfect as the instrument was then considered, it has since been greatly improved, so that it is now automatic, the whole operation of dividing a circle, after it has been placed on the engine, being performed by a motion given by the descent of a weight, or by a crank turned by hand. The engine consists of a large wheel of bell metal, the circumference being ratched into 720, 1,080, 1,440, 2,160, or 4,320 teeth, or any number which, divided by 2, 3, 4, 6, or 12, would give 360. These teeth are cut with great accuracy, and the wheel is turned on its centre by an endless screw, by which it may be moved any number of degrees or parts desired. The dividing point is fixed in a frame which admits of a free and easy motion to and from the centre. In England, Troughton, Simms, Thomas, Jones, and a few others, have been successful in making these engines, while many others have failed. On the continent of Europe they were first made automatic, and other improvements were also made in them. Gambey of Paris has so arranged his as to divide an instrument without any eccentricity, even when placed in a slightly eccentric position on the engine. Oertling of Berlin has an arrangement for correcting any original errors in the teeth while dividing, while other mechanists of celebrity have constructed them to suit their own views, and for their own use. In the United States there is a large one belonging to the coast survey, made by Simms of London, and afterward made auto-

matic by Saxton; also one in Philadelphia made by Young, and one in New York by the Messrs. Blunt, both of which are automatic. There is no branch of the mechanic arts which requires more skill in the use of tools, more geometrical knowledge, and greater patience, than the construction of a circular dividing engine. The large astronomical instruments are divided in a different manner, and unless placed on a large engine from which the divisions may be in a manner copied, are original divisions. Troughton, Simms, and Jones of London have used movable microscopes with micrometers, the method of the former; while others on the continent of Europe have availed themselves of the feeling lever, a powerful instrument for that purpose invented by the astronomer Bessel. Straight line divisions for scales, &c., are made by means of a screw, a milled roller, or a wedge which is employed to move a platform sliding freely beneath a cutting frame, and carrying the scale to be divided. In the use of the screw much depends on its accuracy, and, with regard to the roller or wedge, on the working or manner of applying them. When great accuracy is required, the divisions are tested by means of two microscopes, and an error can be detected of $\frac{1}{50,000}$ of an inch. The ruling machines used by engravers in this country are well calculated for this purpose.

DIVINATION (Lat. *divinatio*, from *divinus*, divinely or prophetically inspired), a general term for the various pretended arts of discovering things secret or future by preternatural means. These arts appear in the remotest antiquity, furnished with rules, founded on mysterious principles, intimately connected with religion, and fortified by the pretences of a science. Both as a learned doctrine and a popular faith, divination has always existed in the East, and was common in Europe throughout classical antiquity and during the middle ages. It was distinguished by the Greeks as natural or artificial; the former being a presage of future events by a spontaneous mental process, by a sort of inspiration or frenzy, which was possible only to persons specially favored by the Deity, as the priestesses of the oracles; the latter being founded on careful observation of certain natural phenomena which were believed to have mysterious relations with future events. Astrologers, augurs, sorcerers, gypsy fortune tellers, and Scotch second-sighted persons, are eminent examples of diviners. The following are among the principal of the numerous and diverse forms of artificial divination practised in antiquity: Alectryomancy was practised by drawing a circle and dividing it into 24 equal parts, into each of which were put a letter of the alphabet and a grain of wheat; a cock was then placed in the centre, and the letters, being put together in the order that the grains were eaten by it, made a word which solved the question of the diviner. Thus Iamblichus of Apamea is said to have learned the name of the successor of the emperor Valens. Arithmomancy depended upon the secret operation of numbers and magical squares, and the numerical value of letters; it was practised by the Chaldeans, and formed a part of the doctrine of the Pythagoreans, Neo-Platonists, and cabalists. Axinomancy consisted in suspending an axe from an upright stick, and the names of suspected persons being pronounced it was supposed to indicate the guilty by its motion. Belomancy consisted in the choice of arrows by chance from a bag containing many of them inscribed with various responses; it was in use especially among the Arabians. Capnomancy consisted either in observing the direction taken by smoke, or in inhaling the smoke of victims, which was believed to produce prophetic inspiration. Dactylomancy was practised by enchanted rings, or rings that were made in harmony with the position of the celestial bodies. Its origin is attributed to Helen, the wife of Menelaus. It is by one of these rings that Gyges is said to have rendered himself invisible. A favorite method was to suspend the ring by a hair within a goblet, when it began to swing, the motion gradually increasing till it struck the tumbler once or twice for yes or no, as previously determined. Gyromancy consisted in walking round in a circle, the circumference of which was marked with letters, the presage being drawn from the letters on which the inquirers stumbled when they became too dizzy to stand. Hydromancy, or divination by water, the invention of which is attributed to the Persians, consisted in observing the colors and images presented by water in a vase, either when motionless or when disturbed by dropping little stones into it. The motions of the agitated waves of the sea were also studied for purposes of divination, especially by the ancient Sicilians and Eubœans. Lampadomancy furnished presages for the future from the form, color, and various fluctuations of the flame of a lamp. Lithomancy was a method of divination by means of precious stones. The sounds of stones striking each other gave presages, and the amethyst was believed to have the virtue of sending dreams prophetic of future events to whoever possessed it. The *bætylia*, or animated stones, of which the Greeks learned from the Persians, and which were believed to bear oracles, are celebrated instances. Ornithomancy, or divination from the flight and song of birds, was a principal function of the Roman augurs. (See AUGUR.) The flame of fire (pyromancy), the accidental opening of a book (rhapsodomancy), the combinations of cards (chartomancy), the drawing of lots, the dropping of staffs or observation of cups (especially in use among the old Egyptians), the interpretation of dreams, the reflections of mirrors, and the contortions of serpents, are other means. Several of these methods of divination are yet in use among the superstitious, even in the most enlightened countries of Europe and America.—Some of the more remarkable forms of divination are fully treated in special articles, as ASTROLOGY, CHIROMANCY, DIVINING ROD, and MAGIC.

DIVING. Though the natural constitution of man entirely unfits him for remaining under water with safety for more than two minutes at a time, the desire of obtaining valuable articles lying at the bottom of the sea has led him to devise numerous expedients, by which he is enabled to lengthen his continuance at moderate depths. By long practice, such as that of the Indian pearl divers of Ceylon, it is stated that this is extended to even 6 minutes; but such accounts are not credited. Admiral Hood, who took pains to time their diving by the watch, found that they were under water in no instance more than a minute. The instance narrated by Dr. Halley of a Florida Indian diver at Bermuda, who could remain two minutes under water, is regarded as an extreme case. In Franchère's "Narrative of a Voyage to the N. W. Coast of America," mention is made of the feats of diving of the Sandwich islanders. Two of them were induced to go down in 14 fathoms of water in search of a couple of sheaves lost overboard. They went down several times, each time bringing up shells as a proof that they had been to the bottom. "We had the curiosity to hold our watches while they dove, and were astonished to find that they remained 4 minutes under the water. That exertion appeared to me, however, to fatigue them a great deal, to such a degree that the blood streamed from their nostrils and ears. At last one of them brought up the sheaves, and received the promised recompense, which consisted of 4 yards of cotton." Tomlinson states "that there is no authentic case of a man being able, under ordinary circumstances, to take in a supply of air sufficient to maintain him under water for two minutes;" and the authorities generally agree in this. Some, however, regard the statements that the divers of Ceylon, in rare instances, remain 6 minutes under water, as not admitting of question, and the statement of Mr. Franchère is entitled to the same consideration. And facts are stated by other authorities which appear to warrant the supposition that this time may possibly be somewhat extended. The lungs retain at each ordinary expiration some carbonic acid gas among their passages. By breathing hard for a short time this is expelled; and if a full inspiration is then taken, the lungs are charged with a large supply of oxygen, and are capable of being sustained a longer time than usual without its renewal. The knowledge of this fact might be of service in some other circumstances, in which it is important to retain the breath the longest possible time, as well as in diving. Again, it is stated that the engineer Brunel, wishing to examine a break in the Thames tunnel, was lowered with another person in a diving bell to the depth of 30 feet, and the break not permitting the bell to go deeper, he dived into the water, holding a rope in his hand. He found no difficulty in continuing under the water fully two minutes, which is explained by the air he inhaled being taken into the lungs under the pressure of a column of water 30 feet high, and consequently condensed into but little more than $\frac{1}{2}$ its ordinary bulk. The lungs, receiving of this air their full capacity, were furnished with nearly double their usual supply of oxygen. The pressure which thus lessens the bulk of air is exerted upon all parts of the body. It is felt by the diver descending from the surface, when at the depth of 15 feet, as a force of 900 lbs. upon every square foot of surface, and increasing about 60 lbs. with every additional foot of descent. The air is with difficulty retained in the chest; the eyes become blood-shot, and blood is ejected from the mouth. Neither these difficulties, however, nor the dangers from sharks, deter the natives of Ceylon from pursuing their avocation as pearl divers, nor those of the Grecian archipelago from gathering the sponges and coral attached to the rocks at the bottom of the sea. In collecting pearls, 10 divers generally go in each boat, half of them resting while the others dive. Each diver is furnished with a sack for securing the oysters he hurriedly gathers at the bottom. He descends holding a rope, by which he is afterward drawn up, and is carried quickly down by placing in his toes another rope fastened to a large heavy stone, which sinks with him. This also is drawn up to be used by the next diver. Some divers carry in their mouth a sponge wet with oil, the object of which is probably to still the ripple upon the surface, and render this smooth and glassy, by which the light is more clearly transmitted to the bottom.—The artificial expedients contrived to render a longer stay beneath the water practicable consist, beside the diving bell, to be particularly described hereafter, either of a partial covering for the body, made water-tight, with a metallic helmet entirely protecting the head; or of water-tight vessels of metal made to enclose the whole body, and furnished with flexible arms and with eye plates of strong glass. Their capacity is sufficient for air to support life for a certain time, the quantity absolutely necessary for this being at least 200 cubic inches per minute; several times as much is allowed. The case is suspended by ropes from a vessel, and is moved about from above, the man within giving signals by a small line held in the hand; his position is face downward, and his hands projecting in the flexible sleeves are at liberty to attach the rope he carries to any objects within his reach. In deep water the pressure is severely felt, forcing the arms and shoulders into the case, so that even a sort of saddle is required upon the back of the man by which he may brace himself more effectually against it. This might be remedied by forcing air through flexible pipes into the case from above. The machine was contrived by Mr. Rowe in 1753, and within the last 20 years has been much improved in the United States. The partial covering, as contrived by M. Klingert, and described in a pamphlet published in Breslau in 1798, possesses important advantages over the tight case, but is still limited in its use

to depths not exceeding 12 or 15 feet. The helmet is made to connect water-tight with a metallic armor around the body, and this with short leather sleeves, and drawers of the same material strengthened within with iron hoops, and securely fastened above the knees. Two flexible pipes connect the interior of the helmet with the air above, one furnished with an ivory mouthpiece through which the air is inhaled The air is expelled from the nostrils and passes out through the other tube. Heavy weights enable the man to keep at the bottom. In 1856 Mr. E. P. Harrington of Westfield, N. Y., recovered the iron safe of the steamer Atlantic, sunk 4 years previously in Lake Erie in about 170 feet of water. The safe itself was at the depth of 157 feet. He made use of a common flexible India rubber armor, unprotected with metal, and supplied with air from an air pump above, this being sent down through a tube of $\frac{3}{8}$ inch bore, composed of 9 alternate layers of canvas and rubber, with a copper wire coiled inside to prevent collapse. He also wore shoes of lead, and carried weights of lead amounting in all to 248 lbs. His first descent was on June 19, and the 18th and last was on the 22d, when he succeeded in attaching a line to the safe, which was in a state room on the upper deck, and it was hauled up. The time of his remaining below increased from one minute the first descent to 11 minutes at the last. At 50 to 70 feet depth all light disappeared. The deck was already covered with a sediment a few inches thick. Mr. H. suffered from extreme chilliness; his strength too, he thinks, was diminished $\frac{9}{10}$. The pressure sometimes caused a violent rush of blood to the head, causing the appearance of bright flashes like electrical sparks.—During the revolutionary war an ingenious but complicated machine, called the American turtle or torpedo, was contrived by Mr. David Bushnell of Connecticut, designed for a sort of submarine boat, which could be propelled along close to the surface by a man within. It contained air sufficient to last half an hour. By admitting a little water in a receptacle made for the purpose, it was made to sink, and could be kept at any desired depth. The water being ejected by two small brass forcing pumps, the machine rose again to the surface. A vessel containing powder enough to blow up a ship was attached outside, and could be freed from the machine, and secured to any object it touched. An apparatus running by clock-work caused the powder to be ignited at any desired interval of time after it was left by the operator. This machine occasioned the greatest alarm among the British ships in New York harbor.

DIVING BELL, a hollow inverted vessel, in which when lowered into the water persons may descend to considerable depths, fresh air being forced down from above to supply the amount required for breathing; and under which upon the bottom they may work to prepare foundations, or to secure articles of value. The principle of the diving bell is seen in pressing any vessel like a tumbler mouth downward into the water. The air within the vessel prevents the water from rising and filling it, but being highly elastic and compressible, it is made to occupy less space as the pressure is increased with the increasing depth of the water. If the vessel were forced down to the depth of 33 feet, it would be found that the water would half fill it, the air being compressed into half its bulk. A little burning taper made to float upon the surface of the water within the vessel makes the relative position of the air and water more conspicuous. Such is the simplest form of the diving bell, as it was known probably in the time of Aristotle, mention being made that divers at that period took down with them a kind of kettle to enable them to remain longer under the water. Beckmann in his "History of Inventions" expresses the opinion that little was known of it before the 16th century. During the reign of Charles V. a satisfactory experiment was tried by 2 Greeks at Toledo, in Spain, in the presence of the monarch and his court, of descending in a large inverted kettle into the water with a burning light, and coming up dry. But this experiment, made by order of Charles to prove the possibility of the thing, and others also undertaken for practical purposes (as recovering sunken treasure) in the course of the succeeding 200 years, were imperfect as there was no provision for renewing the supply of air as it became exhausted, nor for keeping the vessel free from the water forced by the pressure to rise within it. Beckmann also furnishes an interesting account of a ship carpenter, named William Phipps, from Boston, Mass., who persuaded King Charles II., in 1683, to furnish him with a ship and the necessary apparatus for exploring for a rich Spanish ship sunk on the coast of Hispaniola. The experiment was unsuccessful, but on a second trial made in 1687, Phipps was so fortunate as to raise from the depth of 6 or 7 fathoms so much treasure that he returned to England with the value of £200,000 sterling. The account is found in the "History of the British Empire in America," by J. Wynne (London, 1770), and is noticed in Campbell's "Lives of the Admirals." About the year 1715, Dr. Halley contrived a method of furnishing air to the bell while it was at the bottom, thus rendering it unnecessary to hoist it to the surface for new supplies. He had two tight barrels prepared, each with an open bung below, and a hose attached to the top long enough to reach outside below the bottom, in which position the air could not escape through it. These, loaded with weights, were sunk alternately, like two buckets in a well, or, by guys attached to the bell, were made to drop alongside of it. A person within, reaching out into the water under the mouth of the bell, could draw in the hose, and raising the end of it above the level of the top of the cask, the air would be forced upward and furnish a new supply to the bell. All the water would thus be displaced, and one could step about upon the bottom over the area

covered by the bell. The air contaminated by breathing was let off by a stop-cock in the roof, and pieces of glass set in here admitted the light. In the apparatus thus prepared Dr. Halley descended with 4 others, and remained 1½ hours in water over 9 fathoms deep. He soon afterward devised an apparatus with which one could leave the bell, and walk on the bottom for a considerable distance. The diver was furnished with a heavy metallic cap, which was connected with a long flexible tube for conveying air within the bell. Heavy weights were attached to his belt and also to the feet to counteract the buoyancy of the body at great depths. Numerous modifications to the construction of the bell continued to be made by others, none of which however proved to be of much importance until Smeaton, the engineer, applied the air pump about the year 1779 to forcing down the air, and made the first application of the apparatus to engineering purposes. In 1788 he constructed a bell of cast iron, in the form of a chest, 4½ feet long, 4½ feet high, 3 feet wide, and weighing 2½ tons, so as to sink by its own gravity. Those previously made were of wood, loaded externally with weights. With this he cleared the foundations for a pier in Ramsgate harbor, removing stones of over a ton in weight with great facility; and some years afterward it was employed with equal advantage in renewing the foundations, which had been at first made with caissons and failed, with regularly built masonry, consisting of large stones dovetailed together. A bell of this size affords room for two laborers to work at the bottom, and contains air enough, being of the capacity of more than 50 cubic feet, to sustain the life of two persons for more than an hour. In the bell they are supported by seats attached to the sides for the purpose. The air pump, stationed in a boat above, requires the force of several men (sometimes 4) to work it. The quantity of air actually required for each man is about 200 cubic inches per minute at the ordinary pressure of the atmosphere. In the compressed air of the diving bell the same bulk is inhaled, expired, and vitiated at each respiration of the lungs, consequently more is needed than at the surface; and a still larger supply also is requisite to prevent the air from becoming so impure by the mixture of that expired as to endanger the health of the workmen; it is consequently well to provide many times the amount of air that is indispensable. The impure gases rise by their greater heat to the top of the bell, where they escape through the valves provided for this purpose. The glass-covered apertures let in sufficient light to render objects clearly visible when the water is limpid; even the calorific action of the solar rays is not destroyed by their passage through the water. An instance is narrated of a diver at the depth of about 55 feet finding all at once the bell to be filled with smoke. He soon discovered that this came from his cap, which was set on fire by being in the focus of one of the glass lights, through which the solar rays were concentrated. If the water is not clear, the darkness is indescribably dense, even at the depth of only 12 feet. A candle may then be used to advantage if the air is liberally supplied. The increase of pressure experienced in descending in a bell affects individuals differently. Usually a pain is felt upon the tympanum of the ear, caused by the pressure upon the outside not being at once counterbalanced by the air within the tympanic cavity having acquired the same density. The construction of the Eustachian tube, leading from the mouth to the internal part of the ear, is such that a little time is necessary for the compressed air to make its way within. This usually takes place by a sudden impulse, which may be hastened by an effort of the individual like that of swallowing, the mouth and nostrils being closed at the time. When one is unaccustomed to going down, it is often necessary to stop the descent at short intervals to give time for this action to take place. Having reached the bottom, all disagreeable sensations pass away; but on ascending, the expansion of the air within the head excites a painful feeling of distention, which is relieved so soon as the internal and external pressure can be equalized. The practice of descending in diving bells has been thought to be beneficial in some cases of deafness, and also in some affections of the respiratory organs. As the workmen below wish to communicate with those above, they strike a certain number of blows upon the side of the bell, which indicate the desired message according to a system of preconcerted signals. The sound is readily heard above, though noises made at the surface are not heard below. By such signals, or by messages written on wood or other substance, those above are directed to hoist or lower the bell, to move it by the boom from which it is suspended, to renew the supply of air, or to send down or draw up the buckets in which are placed articles found on the bottom. In 1820 a bell was in use for clearing out Howth harbor near Dublin, which measured 6 feet in length, 4 in breadth, and 5 in height. It was of iron cast in one piece, the metal being 3 inches thick at the bottom, and half that thickness at the top; the whole weight was 4 tons, which was much more than sufficient to carry it down. This bell afforded room enough for 4 men. At the bottom they could fill the iron baskets with stones to be hoisted up, and drill the rock for blasts.—In vol. xxii. of the "American Journal of Science" is an interesting account of the experiments made with a diving bell in Portsmouth harbor, N. H., in 1805. The bell inside was 5 feet in diameter at the bottom, 3 feet at the top, and 5¾ feet high. Two men descended in it at a time. When about 12 feet below the surface, the painful sensation experienced in the ears would pass off with a sudden shock, and this would be repeated at each interval of about 12 feet. It might, they found, be avoided by having the bell raised a foot or two every 8 or 10 feet of the descent.

The greatest descent made was about 72 feet. "In a clear day and with an unruffled sea they had light sufficient for reading a coarse print at the greatest depth. As they moved the pebbles with their gaff at the bottom of the river, fish in abundance came to the place like a flock of chickens, and as devoid of fear as if it was a region where they had never been molested by beings from the extra-aquatic world. From the description of the adventurers, no scenery in nature can be more beautiful than that viewed by them in a sunshiny day at the bottom of the deep Piscataqua. It does not appear that the health of either of the men was in the least impaired by their submarine excursions. Their pulsations were quick and their perspiration was very profuse while under water; and upon coming out of it they felt themselves in a fit condition for a comfortable sleep." One of the men, it is further stated, found himself much relieved of rheumatic complaints from which he was suffering, which is attributed by a writer in the *Bibliothèque universelle*, in which the account was translated, to the great heat produced in the bell, which is like that of a steam bath.—An improved form of the diving bell has been recently brought into notice, to which the name of nautilus has been given, and a patent has been issued to Major Sears of New York, who has perfected its construction. Like the torpedos, one form of which has been noticed in the preceding article, it is provided with chambers distinct from those occupied by the divers, but under their control, so that they may at their will be filled either with air or water. By this means the specific gravity of the machine is made to vary so that the bell may rise to the surface or sink to any desired depth. The trap door in the bottom being raised, communication is thus opened with objects outside of or below the bell. Guy ropes from the surface pass through the chamber occupied by the operators, being secured by stuffing boxes in the sides. By drawing upon these the bell is moved in any direction by the persons within. The apparatus has been recently used with success in New York harbor. A diving bell was employed in the operations connected with the removal of the rocks known as Diamond reef in New York harbor, in 1858, which contained a new feature introduced by Mr. Ryerson of New York. In the lower compartment, which was sufficiently capacious to accommodate 6 persons, or for 4 laborers to work together, an arrangement was provided around the sides by which jets of water were allowed to play in, causing a fine spray, the effect of which was to wash the air and free it in part, at least, of the carbonic acid generated by respiration.

DIVINING ROD. The increase of knowledge has not yet expelled even from the best educated portions of the United States all faith in the magic virtues of this instrument. There is a mystery in the hidden flow of subterranean courses of water, and in the occurrence of deposits of valuable ores, which encourages a resort to mysterious methods for discovering them. If the wise can point to no sure clue to them, the ignorant pretender does not fail to find one, which to many is all the more acceptable for its extravagant pretensions and inexplicable nature. It is stated by a writer in the "American Journal of Science" (vol. xi., 1826) that the divining rod has been in frequent use since the 11th century. A work was published in France in 1781 detailing 600 experiments made to ascertain the facts attributed to it, "by which is unfolded," according to this work, "their resemblance to the admirable and uniform laws of electricity and magnetism." These sciences still continue to be appealed to in order to support in some vague way phenomena which defy other means of explication. As commonly used, the divining rod is a forked slender stick of witch hazel; elastic twigs, however, of any sort, or even 2 sticks of whalebone fastened together at one end, do not appear to be rejected in the want of the hazel tree. One branch of the twig is taken in each hand between the thumb and fore finger, the 2 ends pointing down. Holding the stick in this position, the palms toward the face, the gifted operator passes over the surface of the ground; and wherever the upper point of the stick bends over and points downward, there he affirms the spring or metallic vein will be found. Some even pretend to designate the distance below the surface according to the force of the movement, or according to the diameter of the circle over which the action is perceived, one rule being that the depth is half the diameter of this circle; whence the deeper the object is below the surface the further is its influence exerted. It is observable that a rod so held will of necessity turn, as the hands are closed more tightly upon it, though this has at first the appearance of serving to resist its motion. From the character of many who use the rod and believe in it, it is also plain that this force is exerted without any intention or consciousness on their part, and that they are themselves honestly deceived by the movement. On putting the experiment to the test by digging, if water is found it proves the genuineness of the operation; if it is not found, something else is, to which the effect is attributed, or the water which attracted the rod is sure to be met with if the digging is only continued deep enough. Some ingenuity is therefore necessary to expose the deception. The writer above referred to succeeded in showing the absurdity of the operation by taking the diviners over the same ground twice, the second time blindfolded, and each time marking the points designated by the rod. This, however, is a test to which they are not often willing to subject their art. Some operators do not require a forked twig. There was in 1857, and may be still, within less than 100 miles of New York city, a man who believed himself gifted in the use of the divining rod, and was occasionally sent for to go great distances to determine the position of objects of value sunk in the lakes,

of ores, and of wells of water. He carried several little cylinders of tin, but what they contained was a secret. One had an attraction for iron, another for copper, a 3d for water, &c. He had in his hand a little ratan cane, which he used as not likely to excite the observation of those he met. Taking one of the cylinders out of his pocket he slipped the ratan into a socket in its end, and holding in his hands the other end of the stick, he set the contrivance bobbing up and down and around. That it was attracted and drawn toward any body of ore in the vicinity he was evidently convinced.

DIVISIBILITY. To what extent particles of matter may be subdivided we are restricted from ascertaining by experiment, through the imperfection of our senses; or by metaphysical reasoning, through our want of mental capacity. Dr. Thomson caused a grain weight of nitrate of lead dissolved in 500,000 parts of water to be decomposed, and the sulphuret of the metal formed by the action of a current of sulphuretted hydrogen to appear in a visible form diffused throughout the whole quantity of water. Each drop and each microscopic portion of a drop contained the metallic salt, which he hence concluded was divided into at least 500,000,000,000 parts, and each of these contained its proportional quantity of lead and of sulphur. The mechanical subdivision of ductile metals is hardly less remarkable. By drawing a wire coated with 8 grains of gold, this may be made to reach $2\frac{1}{2}$ miles. Wollaston drew down a platinum wire of the diameter of $\frac{1}{1000}$ of an inch, enclosed in a coating of silver making the thickness $\frac{1}{5}$ of an inch, until the two were reduced to $\frac{1}{1500}$ of an inch. The silver being dissolved by nitric acid, the platinum wire was left, the thickness of which must have been $\frac{1}{30,000}$ of an inch. The microscopic observations of Leeuwenhoeck have developed some wonderful facts respecting the tenuity of the spider's web. The common thread is known to be made of 4 strands, each of which is visible to the naked eye, and this is found to consist of at least 1,000 small threads which issue from as many orifices in the spinner of the animal. Of the smallest spiders Leeuwenhoeck estimated that the quadrupled thread was so minute that at least 4,000,000 of them would not exceed in thickness one of the hairs of his beard; and as each of these is made up of at least 4,000 fibres, it must follow that each fibre can be no larger than $\frac{1}{16,000,000,000}$ of a human hair. Nothing perhaps more sensibly exhibits the principle of the extreme divisibility of matter than the diffusion of odors. Musk, without appreciable diminution of weight, continues for months to impart its odor to an apartment, the air of which is constantly renewed. Every portion of the air that has passed through the room has evidently taken with it a portion of musk, and yet so small is the aggregate amount that we have no other means of showing that the original quantity has been diminished. According to the demonstration of Dr. Keill, any given quantity of matter, however small, may be diffused through any given finite space, however large, and so fill it that there shall be no pore in it the diameter of which shall exceed any given line.

DIVORCE. In a popular sense, divorce is a dissolution of the bond of matrimony, for causes occurring after marriage. Jurists, however, in treating of the subject, usually include also another class of cases, viz.: those in which the marriage may be deemed by a court to have been null *ab initio* upon antecedent grounds; as where such marriage was accomplished by force or fraud, or where, by reason of near consanguinity of the parties, the marriage was unlawful. The common law allowed divorces *causa impotentiæ seu frigiditatis*, if such impotence or frigidity existed before marriage, this being deemed a fraud; but it was no ground of divorce if it supervened after marriage; and it is the only kind of fraud of which we find mention in the English cases as a ground of annulling a marriage. Fraudulent representations by either party in respect to his or her condition in life, pecuniary circumstances, family connections, bodily health, and the like, however material these may have been in inducing a consent to the contract, still are unavailable as an impeachment of the marriage. A false personation of another, or any fraud by which one of the parties is deceived in respect to the person with whom the marriage is solemnized, is a sufficient cause for annulling the marriage; but this is put upon the ground of want of consent, it being equally essential to this as to other contracts that there should be the *animus contrahendi*, and the contract cannot take effect contrary to the real intention of the party who is to be bound. In the English courts the proceeding *causa jactitationis matrimonii* was intended for relief in such cases; in form, being an action by the one party for an alleged assertion by the other that a marriage has taken place, whereupon the matter is tried, and unless the defendant proves that there was a marriage he is prohibited from averring the same, which is equivalent to a decree that there was no such marriage. In the state of New York it was formerly held that physical incapacity existing before marriage was not a ground of divorce, for which decision the reason assigned was that the English ecclesiastical law had never been adopted in this country. By the Revised Statutes of New York it is provided that a divorce may be granted where one of the parties was physically incapable of entering into the marriage state, and also where the consent of one of the parties was obtained by force or fraud (2 R. S. 142). The nature of the fraud referred to is not defined, but it may be presumed that it must be some imposition or deception relating to the ceremony itself; and probably it would be held, in conformity with the English rule, that if it was really intended that the marriage should take place, and if it has in fact been solemnized with the

person intended, such marriage will be valid, notwithstanding consent was obtained by fraudulent representations in respect to other matters which may have constituted the inducement to the consent. If, however, there has been any intimidation used, it is a sufficient cause for annulling the marriage, and this seems to have been the true ground of the decision in the case of Fierlat *vs.* Gojon (Hopkins's Rep. 478), though it was put mainly upon the ground of fraud. Voluntary cohabitation of the parties as husband and wife is a bar to dissolution of the marriage, either for force or fraud.—The degree of kindred in which marriage is lawful in England is the 4th, according to the computation of the civil law; that is, counting the degrees of the ascending and descending lines. Marriage is, therefore, lawful between first cousins, or between great uncle and niece, but not between uncle and niece. And the same prohibition extends to relationship by marriage; therefore a man is not permitted to marry his deceased wife's sister, mother, or aunt, nor his stepdaughter nor daughter-in-law. By statute in the state of New York the prohibition extends only to relatives who are lineally related, and to brothers and sisters, whether of the half or whole blood (2 R. S. 129). In France marriage is prohibited between lineal ascendants and descendants; between brothers and sisters, whether legitimate or illegitimate; between uncle and niece, aunt and nephew; and also between those who are related by affinity in the same degrees; but in the case of uncle and niece or aunt and nephew a dispensation can be granted for weighty reasons. (*Code civile*, art. 161–164.) The same was substantially the rule of the Roman law, except that marriage of uncle and niece or aunt and nephew was considered incestuous, and under no circumstances was admitted, and the prohibition was extended to uncle and grand niece or aunt and grand nephew. Relationship by adoption was equally within the prohibition while such relationship continued to exist, as between brother and adopted sister; but if the sister was emancipated, marriage between them became lawful; and without such emancipation, the brother could marry an adopted sister's daughter. But there could be no marriage between those lineally related by adoption, either before or after emancipation, as between father and adopted daughter or granddaughter. (Justinian, Inst., lib. i. tit. 10.) In the English ecclesiastical courts there was formerly another ground upon which marriage could be annulled, viz., a prior engagement with another party. But this was abrogated by stat. 26 George II., c. 33, which prohibited all suits to enforce performance of a marriage contract; the parties being thus left to an action for damages upon refusal to perform it.—We have next to consider divorce for causes occurring after marriage. In England, from a very early period, divorce *a vinculo matrimonii* was not allowed for such causes, but only a separation *a mensa et thoro*, which did not authorize either party to marry again. This practice was derived from the canon law, which held marriage to be a sacrament, and that it could not be dissolved for any cause whatever. But by statute 20 and 21 Victoria, c. 85 (1857), divorce *a vinculo* is now allowed on the petition of the husband for the adultery of the wife, and on the petition of the wife when the husband has been guilty of incestuous adultery, rape, bestiality, or adultery accompanied by cruelty. Divorce *a mensa et thoro* is by the same act denominated a decree of judicial separation, and under that designation is allowed for the same causes as heretofore. A new tribunal, called the court for divorce and matrimonial causes, has been established, and the jurisdiction of the ecclesiastical courts has been entirely superseded in such matters, except the granting of marriage licenses.—By the Roman law marriage was held to be dissoluble at the pleasure of either party, the dissolution being called in such cases *divortium sine causa* or *sine ulla querela*. Augustus attempted to impose restrictions upon voluntary divorces, but his authority was unavailing against this evil. Justinian, by an imperial edict, prohibited voluntary divorces; but this was repealed by his successor, Justin, and the old law was restored, allowing full freedom of dissolving marriage by mutual consent. It appears that under the Christian emperors divorces *sine causa*, or at the option of one of the parties, were no longer allowed, but the causes which were held sufficient afforded ample facility for separation, with a preponderating advantage in favor of the husband. "In the most rigorous laws a wife was condemned to support a gamester, a drunkard, or a libertine, unless he were guilty of homicide, poison, or sacrilege, in which cases the marriage, as it would seem, might have been dissolved by the hand of the executioner." (Gibbon, c. 44.) Adultery of the wife was available to the husband as a ground of divorce, and either party was allowed a release from the matrimonial obligation for incurable impotence of the other party, whether existing before marriage or occurring afterward; for desertion, or long absence; and on the assumption of the monastic profession.—The *Code civile* of France allowed divorce: 1, for adultery of the wife, but not for adultery of the husband except when he brought a paramour or concubine into his own house; 2, to either party for any outrage, cruelty, or grievous wrong inflicted upon him or her by the other party (*pour excès, sévices, ou injures graves*); 3, to either upon the condemnation of the other to an infamous punishment (*condemnation à une peine infamante*), which is elsewhere defined to be either imprisonment, banishment, loss of civil rights, or being placed in the public stocks (*attaché au carcans sur la place publique; Code pénal*, arts. 8 and 22); 4, by mutual consent, with other satisfactory proof that the continuance of the marriage would be insupportable (*que la vie commune leur est insupportable*). These provisions were rescinded in the religious reaction of

1816. A law was passed (May 8, 1816) effacing divorce from the *Code civile*, and reëstablishing the old law, which allowed only *séparation par corps*. Ineffectual attempts were made in 1831 and 1832 to repeal this law, and there is therefore at present no divorce *a vinculo matrimonii* in France.—The Prussian laws (*Landrecht*), framed under Frederic the Great, who is well known to have been by no means a friend of marriage life, have established a facility of divorce greatly beyond any precedent in modern Europe; as for incurable impotency, although occurring after marriage; madness continuing a year; inexcusable desertion (*Verlassung*); drunkenness, or other disorder, of long continuance; ineradicable repugnance, and several other causes.—The law of divorce in the United States is various in different states. In New York, jurisdiction of all cases, whether of divorce *a vinculo*, or of limited divorce *a mensa et thoro*, was given by statute to the court of chancery, and upon the abolition of that court it vested in the supreme court in the exercise of equity power. Adultery of either party is the sole cause occurring after marriage, for which a divorce *a vinculo* can be granted. It is, however, provided that sentence of imprisonment to the state prison for life is civil death (2 R. S. 701), and the husband or wife of such imprisoned person is at liberty to marry again without the necessity of any judicial action. Imprisonment for a less term than for life merely suspends civil rights, but does not abrogate them; and the convict, upon expiration of his term, resumes his marital rights. No provision is made by law for the case of long continued absence, except that there is an exemption from the penalty of the statute against bigamy in the case of a second marriage, when the former husband or wife has been absent 5 successive years without being known to the other to be living (2 R. S. 687), but the second marriage is not thereby made valid. In some of the states jurisdiction has not been conferred upon the courts to grant divorces, and the power rests solely with the legislature; and in others, although there is judicial authority, yet applications to the legislature are also made. In all the states adultery of either party is a ground of divorce. In Massachusetts, Maine, and New Jersey, wilful desertion for 5 years; in Indiana and Missouri, desertion for 2 years, cruel and inhuman treatment by the husband, or his habitual drunkenness for 2 years; in Ohio, wilful desertion for 3 years, and habitual drunkenness for the same period; in Vermont, imprisonment in state prison for 3 years; in Pennsylvania, wilful desertion for 2 years; in Connecticut, wilful desertion for 3 years, or 7 years' absence without being heard of; also constitute sufficient grounds of divorce. In the state of New York a limited divorce *a mensa et thoro* is granted on the complaint of the wife for cruel and inhuman treatment, or such conduct as makes it unsafe and improper for her to cohabit with her husband, or for wilful desertion and refusal or neglect to provide for her. Applications to the legislature for a divorce have been most frequent in Vermont, Connecticut, and some of the western states. In Connecticut no petition for a divorce can be acted upon in a case where the courts are competent to give relief. In other states, as Virginia and Kentucky, such an application is usually referred to the courts for investigation. An interesting and difficult question often arises as to the effect to be given in one state to a divorce obtained in another. It has been incidentally held by the federal courts that laws for the dissolution of the marriage contract for cause, are not within the prohibition of the constitution against laws impairing the obligation of contracts, though it might be otherwise as to a law which should allow a dissolution without cause. A divorce granted by the courts of the state where the parties are domiciled, or rather where the defendant is domiciled, at the time the divorce is pronounced, may be considered as valid everywhere. This should perhaps be qualified by a further assumption that the parties have been regularly brought before the court or legislature by proper process. It is a fundamental principle that no one is bound by any judicial proceeding to which he has not been regularly made a party by personal service of process, or such notice as is declared by law to be equivalent thereto. As between citizens of the same state (or perhaps it would be more proper to say residents, for there is no distinctive citizenship of a state except residence), any provision of law substituting notice by publication or otherwise instead of personal service, would undoubtedly be binding; but when the defendant in the proceeding is at the time of the commencement thereof a resident of another state, it is questionable if any thing but personal service within the state where the proceeding is commenced, would be held sufficient to give jurisdiction. In the state of New York it was held that a divorce granted by a court in Vermont, in a suit in which there had been no service of process except by publication, defendant being then a resident of New York, was void, although the record recited that the defendant had been duly notified to appear. (Borden *vs.* Fitch, 15 Johnson, 121.) Later cases in that state, however, would rather lead to the conclusion that the record will be held to be conclusive, except that when an appearance has been entered by attorney the authority of such attorney may be disproved. (Shumway *vs.* Stillman, 4 Cowen, 292.) Still it has been denied that there can be any proper record if the parties have not been regularly before the court (Starbuck *vs.* Murray, 5 Wendell, 148; Bradshaw *vs.* Heath, 13 Wendell, 407); and a late decision in the court of appeals takes the broad ground that even in the same state in which a judgment was rendered, the judgment is of no validity against a party not personally served with process (Oakley *vs.* Aspinwall, 4 Comstock, 513). If, however, an inhabitant of one state goes into another for the express purpose of getting a divorce for a cause which would not au-

thorize a divorce in the state of his domicile, this has been held to be a fraud, and that the divorce would not be recognized in the latter state. (Barber *vs.* Root, 10 Mass. Rep. 264; Mass. Rev. Stat.)—In respect to divorces by foreign tribunals, it may be safely laid down as a general rule that they are valid if the parties were properly before the court. For this purpose it would be necessary that the defendant should have been served with process within the jurisdiction of the foreign court. There has been a serious conflict between the courts of England and Scotland as to the effect of a divorce in the latter country for causes not admitted as a sufficient ground in the former. The English courts formerly insisted that the *lex loci contractus* must govern, and that an English marriage could not therefore be dissolved by the courts of another country, although the parties (or the defendant, which it may be presumed is all that is material) should be domiciled in such country. (Lolly's case, 1 Dow P. C. 124; Tovey *vs.* Lindsay, 1 Dow Rep. 117; Conway *vs.* Beazley, 3 Hagg Eccl. Rep. 639.) But it was finally decided by the house of lords that a valid dissolution of marriage contracted in England might be made in Scotland. (Warrender *vs.* Warrender, 9 Bligh, 89.) Yet it is still maintained in the English courts that no decision made in the courts of another country can affect the rights of parties to lands in England, and therefore that the child of unmarried parents domiciled in Scotland who afterward married there, could not inherit lands in England. (Birtwhistle *vs.* Vardill, 9 Bligh, 72.) With some incongruity the same courts have held that the right of succession to lands in Scotland, by a child of parents residing in the state of New York who were afterward married, must be determined by the law of New York and not of Scotland. But whatever may be the doctrine of the English courts, there can be no doubt that in this country a foreign decree of divorce would be recognized as valid in any case where jurisdiction had been properly acquired by service of process on the party against whom such decree is made.

DIX, Dorothea L., an American philanthropist, born in Worcester, Mass. Her father was a physician, and after his death she supported herself by teaching a select school for young girls in Boston. While thus engaged she was one day passing through a street of that city, and overheard two gentlemen who were walking before her conversing upon the state prison at Charlestown, and complaining of the neglected condition of the convicts. Their remarks affected her so powerfully, that she could not rest until she had visited the prison herself. She became deeply interested in the welfare of the unfortunate and suffering classes, for whose elevation she labored until 1834, when, her health becoming impaired, she gave up her school, and embarked for Europe. Shortly before this she had inherited from a relative sufficient property to render her independent of daily exertion for support. In 1837 she returned to Boston, and devoted herself to investigating the condition of paupers, lunatics, and prisoners. In this work she was warmly encouraged by her friend and pastor, the Rev. Dr. Channing, of whose children she had been the governess. Since 1841 Miss Dix has given her time and influence entirely to this work, and in the prosecution of it has made many long and laborious journeys, having visited every state of the Union east of the Rocky mountains, examining poorhouses, prisons, lunatic asylums, and endeavoring to persuade legislatures and influential individuals to take measures for the relief of the poor and wretched. Her exertions contributed greatly to the foundation of state lunatic asylums in Rhode Island, Pennsylvania, New York, Indiana, Illinois, Lousiana, and North Carolina. She presented a memorial to congress during the session of 1848–'9, asking an appropriation of 5,000,000 acres of the public lands to endow hospitals for the indigent insane. The measure failed, but she renewed the appeal in 1850, asking for 10,000,000 acres. The committee of the house to whom the memorial was referred made a favorable report, and a bill such as she asked for passed the house, but failed in the senate for want of time. In April, 1854, however, in consequence of her unwearied exertions, a bill passed both houses of congress, appropriating 10,000,000 acres to the several states for the relief of the indigent insane; but the bill was vetoed by President Pierce, chiefly on the ground that the general government had no constitutional power to make such appropriations. Miss Dix has published several works anonymously. The first, the "Garland of Flora," appeared in Boston in 1829, and was succeeded by a number of books for children, among which were "Conversations about Common Things," "Alice and Ruth," and "Evening Hours." She has also published a variety of tracts for prisoners, and has written many memorials to legislative bodies on the subject of lunatic asylums. Miss Dix is gifted with a singularly persuasive voice, and with manners that are said to possess a remarkably controlling influence over the fiercest maniacs. She has recently been in Europe, and is now (April, 1859) again exploring the United States on her ceaseless mission of benevolence.

DIX, John Adams, a U. S. senator from New York, born in Boscawen, N. H., July 24, 1798. During the war of 1812–'15 he served on the frontier as an ensign, and subsequently acted as adjutant of a battalion. At a later period he was aide-de-camp to Gen. Brown, commander-in-chief of the army. Having married, and travelled extensively abroad, he established himself about the year 1828 as a lawyer at Cooperstown, N. Y., and becoming identified with the democratic party, he soon turned his attention to politics. In 1830 Gov. Throop appointed him adjutant-general of the state. In Jan. 1833, he was chosen secretary of state. By virtue of his office he was superintendent of common schools and a member of the canal board, and one of the commissioners of the canal fund. The last two

bodies have charge of the vast works of internal improvement of New York, and also of its complicated financial affairs. While he was in office new canals were being constructed, the enlargement of the Erie canal was commenced, and the network of railways that now covers the state was just starting into existence. Having been out of office for some time, he was elected a member of the assembly in 1842, from Albany co., and in the winter of 1845 was chosen to fill a vacancy in the U. S. senate, caused by the election of Silas Wright as governor. He remained in this new field till March 4, 1849, and bore a distinguished part in discussing the great questions of that stormy period—the annexation of Texas, the war with Mexico, the joint occupation and disputed boundary of Oregon, and the power of congress over slavery in the territories. On the question of slavery he was the exponent of the views of the free-soil section of the democratic party in New York, whose candidate for governor he was in 1848, when Mr. Van Buren was a candidate for the presidency in opposition to Gen. Cass, both Dix and Van Buren standing upon the "Buffalo platform." While in the senate, he was chairman of the committee on commerce, and a leading member of the committee on military affairs. He brought in a bill for reciprocal freedom of trade with the British provinces—substantially like that passed 6 years later—and supported it in 2 speeches which display an intimate acquaintance with the trade and resources of both countries. He was the author of the act defining the duties and reducing the salaries of officers of the customs in the large ports. The divisions in the democratic party of New York, arising out of the slavery question, rendered his reëlection to the senate impossible; and he was succeeded by Mr. Seward. Having taken an active part in 1852 in favor of the election of Mr. Pierce to the presidency, his immediate friends in the democratic party desired that he should be appointed secretary of state, and he was at first selected for that post by Mr. Pierce. But, difficulties seeming to arise in the mind of the president elect, Gen. Dix was induced to decline in favor of Gov. Marcy. He afterward accepted in 1853, as a temporary employment, the post of assistant treasurer in New York city; but dissatisfied with the president's conduct in relation to the appointment of a minister to France, he resigned his office, and has since taken no part in politics beyond an occasional speech before some popular meeting of the democratic party. He has travelled extensively in Europe, and now devotes much attention to study and the management of a large estate. He is the author of "Resources of the City of New York" (8vo., New York, 1827); "Decisions of the Superintendent of Common Schools of New York, and Laws relating to Common Schools" (8vo., Albany, 1837); "A Winter in Madeira" (12mo., New York, 1851); and "A Summer in Spain and Florence" (12mo., New York, 1855).

DIXON, George, an English navigator, died about 1800. He sailed in Cook's 3d expedition. On his return he was promoted to the rank of captain in the navy, and in 1785 in concert with Capt. Portlock sailed on a new expedition, consisting of 2 vessels, under the auspices of the Nootka sound company. In the course of their joint explorations they discovered a number of harbors, ports, bays, and small islands on the coast of North America, and arrived at Hawaii, Sept. 28, 1786, whence Dixon proceeded to China. He is the author of a description of his own expedition, under the title of "A Voyage round the World, but more particularly to the N. W. Coast of America," &c. (London, 1785–'88).

DIXON, James, D.D., an English clergyman of the Wesleyan Methodist church, entered the Wesleyan conference in 1812; in 1824 was stationed in the Gibraltar mission, where he labored for 3 years; in 1828 he was stationed on one of the London circuits, and remained in London until 1833; thence he was sent to Liverpool, and afterward was successively superintendent of Sheffield and Manchester circuits. In 1848 he was appointed by the Wesleyan conference a delegate to the general conference of the Methodist Episcopal church which was held at Pittsburg, Penn. On his return home he published an account of his visit to the United States. In 1841 he was chosen president of the British conference, and in accordance with established usage he preached the "conference sermon," in 1842, on "Methodism, its Origin, Economy, and Present Position." This sermon was subsequently elaborated into a book bearing the same title, beside which he published a "Memoir of the Rev. William E. Miller," and about the same time a work entitled "The Present Position and Aspects of Popery, and the Duty of exposing the Errors of Papal Rome," and "Letters on the Duties of Protestants with regard to Popery."

DIXON, William Hepworth, an English author and critic, editor of the London "Athenæum," born in the county of York in 1821. He was educated at a provincial school, and evinced an early genius for literature by the composition of a tragedy in 5 acts. After conducting a newspaper for a considerable period at Cheltenham, he gained prizes for two successive essays thrown open to unlimited competition by Mr. Madden of London, proprietor of the "Prize Magazine." These attracted the attention of many eminent persons, among others of Mr. C. Wentworth Dilke, who soon engaged Mr. Dixon as a contributor to the columns of the "Athenæum." In a short time he became the critical editor of this periodical, and on the retirement of Mr. T. K. Hervey in 1853 was appointed to its sole direction, an office which he continues to hold. He removed to London in 1845, since which time his published works, chiefly historical and biographical, have taken standard rank. The first was entitled "John Howard the Philanthropist, and the Prison World of Europe" (London, 1850; 5th ed. 1854), and was followed in the same year by the "Lon-

don Prisons," a volume amplified from a series of communications to the "Daily News" newspaper. In 1851 appeared his "Life of William Penn," and the 3d edition in 1856, with an "Extra Chapter on the Macaulay Charges," concerning which much controversy has arisen. His "Life of Admiral Blake," based on family and state papers, was published in 1852 (2d ed. 1858). After the publication of his biography of Penn, the Pennsylvania historical society elected him an honorary member. He also produced in 1852 a work entitled the "French in England; or Both Sides of the Question on Both Sides of the Channel." As deputy royal commissioner for the great exhibition of 1851 he was eminently successful; and as a representative of the ballot society, the principles of which he advocated in an extensive political tour, he received the offer of a seat in parliament. He declined the honor, being resolved upon the execution of a national work, a history of England during the rebellion and under the commonwealth. For this he has ransacked the state paper office, and explored every site and scene in the old world at all connected with the events of the period, studying documents, men, and manners. He purposes also to visit America with similar objects in view. In his capacity of editor of the "Athenæum" Mr. Dixon forms the centre of a large and brilliant literary circle.

DIXWELL, John, colonel, one of the judges of Charles I., born in 1608, died March 18, 1689. After the reaction in England which placed Charles II. upon the throne, and caused himself and his associates to be condemned to death, he escaped to America. He changed his name, taking that of John Davids, and lived undiscovered among the inhabitants of New Haven, where he was married and left children. In 1664 he visited two of his fellow regicides, Whalley and Goffe, who had found a refuge amid the solitudes of Hadley, a township of Massachusetts. His favorite study in exile was the "History of the World," which Raleigh had written in prison, and he cherished a constant faith that the spirit of liberty in England would produce a new revolution.

DLUGOSZ (Lat. *Longinus*), Jan, a Polish historian, born at Brzeznica in 1415, died in Cracow, May 29, 1480. He studied at the university of Cracow, found a patron in the cardinal Zbigniew Olesnicki, took orders, was made canon of Sandomir, and subsequently of Cracow. Casimir IV. employed him in several important diplomatic missions to John Hunniades, governor of Hungary, the pope, the emperor, George Podiebrad of Bohemia, the grand master of the Teutonic order, and Matthias Corvinus of Hungary. Casimir also intrusted him with the education of two of his sons, Ladislas, who still remained under his guidance when elected king of Bohemia, and John Albert, afterward king of Poland. Shortly before his death he was appointed archbishop of Lemberg. He left in manuscript a number of works in Latin, of which the history of Poland, from the origin of the nation down to the last year of the author's life, is one of the most valuable historical productions of that age. The first partial edition of this work appeared at Dobromil in 1615; the first complete edition in 2 vols. at Frankfort and Leipsic in 1711 and 1712, under the title of *Joannis Dlugossi seu Longini Canonici quondam Cracov. Historiæ Poloniæ libri XII.* Measures for the publication of a new Latin and Polish edition of his complete works were set on foot in 1858, under the auspices of Count Vladimir Plater.

DMITRIEFF, Ivan Ivanovitch, a Russian poet and minister of justice, born in the government of Simbeersk in 1760, died in Moscow in Oct. 1837. Having studied for some time at Kasan and Simbeersk, he removed with his father, on the revolt of Posgatcheff, to St. Petersburg, where he entered a military school, and subsequently the active service. On the accession of Paul he left the army with the rank of colonel, sat in the senate, was made privy councillor, and under Alexander I. became minister of state, which office he resigned after 4 years, and retired into private life. He aided Karamsin in promoting a new movement in the Russian language and literature, writing himself popular songs, fables, and tales, mostly after Lafontaine, Florian, and others, excellent satires, and an epico-dramatic poem, *Yermak*, as well as his own memoirs, a part of which he published. There are several editions of his complete works.

DNIEPER, Dniepr, or Dnepr (anc. *Borysthenes*, also *Danapris*), next to the Volga the largest river of Russia in Europe, rises on the S. slope of the Volkonsky plateau, near Dneprovsk in the government of Smolensk, flows S. between woody marshes as far as Drohobush, thence W. between more elevated banks to Smolensk, continues its western course as far as Orsha, takes then a S. course, passes through the meadowy valleys and fertile plains of the government of Mohilev down to Kiev, turns then S. E. through the steppes of the Ukraine, passes by Krementshug and Ekaterinoslav, flows S. as far as Alexandrovsk, and then W. S.W. to its mouth below Kherson, emptying into the Black sea between Kinburn and Otchakov. Its whole course is about 1,100 m. Its chief tributaries are, on the right, the Beresina, the Pripetz, which empties into it the waters of the Lithuanian marshes, and the Inguletz; on the left, the Desna and Vorskla. Though large, the Dnieper was formerly hardly navigable, owing to natural obstructions in its lower course and at the mouth. Some of these have been removed by the Russian government, but its commercial importance is still lessened by its frequent shallowness. About lat. 48° 20′ N. it commences a course of more than 40 m. over a rugged bed of granite, forming below Ekaterinoslav a number of cataracts and rapids (in Russian *porogs*, whence the name of Zaporogian Cossacks), and separates into a great number of courses, embracing many woody islands. Reuniting, it becomes navigable in its lower course for flat-

bottomed vessels, among which steamboats have been employed since 1838 in carrying the produce of the interior, timber, corn, linen, iron, and coal, to the Black sea. The Beresina, Oginski, and King's canals, connecting tributaries of the Dnieper with the Düna, Niemen, and N. Bug, form water communications through these rivers between the Baltic and Black seas. The estuary or lake (Russ. *liman*), formed by the mouths of the Dnieper as well as by that of the Bug, is very shallow, and emits noxious exhalations during the hot summer months. The Dnieper, like the Volga, abounds in sturgeon, carp, pike, and shad. In its long course it passes through the most fertile provinces of Russia, and through different climates. At Smolensk it freezes in November and remains icebound till April; at Kiev it is frozen over from January to March. The most remarkable bridges over the river are in these 2 cities. The ancients regarded the Borysthenes as the largest river of the world next to the Nile, and entertained an exaggerated opinion of the fertility of the surrounding country. They knew only its lower course. Near its mouth was Olbia, or Olbiopolis, a colony of Miletus, which carried on trade with the nomadic tribes of the interior.

DNIESTER, or Dniestr (anc. *Tyras* and *Danaster*), a river of eastern Europe, which rises on the N. side of the Carpathian mountains, near Turka in Austrian Galicia, flows mostly S. E. for about 500 m., passes by Sambor, Halicz, and Mariampol in Galicia, and Chocim, Mohilev, and Bender in Russia, separates the Russian province of Bessarabia from Podolia on the W. and Kherson on the E., and empties into the Black sea between Akerman and Ovidiopol. Its principal tributaries are the Stry and Sered. There is but little navigation; its mouth is encumbered with flats and sandbanks.

DOAB (Sanscrit, two waters), a name given in Hindostan to any tract of country included between 2 rivers. It is especially applied to the tract lying between the Ganges and the Jumna, and when applied to other similar districts is joined with some distinctive appellation, as the Jallunder Doab, between the Beas and the Satlej, and the Rukna Doab, between the Ravee and the Chenab. The Doab, so called by way of eminence, is a large tract reaching from Allahabad in the south to Saharanpoor in the north, and forming the finest and most fertile part of the province of Agra. It contains many thriving towns, and the whole territory has been brought into a highly productive state by means of a system of irrigation.

DOANE, George Washington, D.D., LL.D., an American clergyman, 2d bishop of the Protestant Episcopal church in the diocese of New Jersey, born at Trenton, N. J., in 1799, died at Burlington, N. J., April 27, 1859. He was graduated at Union college, Schenectady, in 1818; in 1821 was admitted to holy orders; officiated for 3 years in Trinity church, New York; in 1824 was appointed the first professor in Washington (now Trinity) college, Hartford. In 1828 he became assistant minister, and then rector of Trinity church, Boston, where he continued to officiate until 1832, when he was elected and consecrated bishop of New Jersey, whereupon he removed to Burlington, and became rector of St. Mary's church in that city. Here he devoted his energies to the establishment of a comprehensive system of Christian education for females. In pursuance of this plan, in 1837 he established St. Mary's hall, a boarding school for girls, beautifully situated on the shore of the Delaware, in which 200 girls from every state in the Union, as well as from foreign countries, are carefully educated in the tenets of the Episcopal church. In consequence of the great success of this enterprise, he founded Burlington college in 1846, under a charter from the state legislature; on Jan. 1, 1858, this institution had 29 instructors and 118 students. Bishop Doane's theological controversies were frequent. As a writer and preacher his style is not only peculiar, but his language robust and eloquent. His contributions to literature and theology were many and voluminous, and his poems have been much admired. Under his episcopate the church in New Jersey experienced an unexampled increase in the number of its communicants, from 801 in 1832 to 4,500 in 1858, while the clergy increased from 14 to 90 in the same period, and the number of parishes from 31 to 79.

DOBBIN, a family in Baltimore, long connected with the newspaper press of that city. Archibald Dobbin, and his sons Thomas, Archibald, George, and Robert, emigrated from the north of Ireland, and settled in Baltimore in 1790. Thomas Dobbin published the first daily newspaper in that city in 1795, called the "Baltimore Telegraph," which was continued after his death in 1809 by his brother George, in connection with Thomas Murphy, under the name of the "American." George Dobbin died in 1811, leaving two sons, Robert A. and George W. Robert A. succeeded in the management of the newspaper, and is still connected with it. The "American" is one of the oldest commercial journals of the Union, and has been under the control of the same family for 64 years. It is now published by R. A. Dobbin and Charles C. Fulton, under the title of the "Baltimore American and Commercial Advertiser."

DOBBIN, James Cochrane, an American statesman, born in Fayetteville, N. C., in 1814, died there, Aug. 4, 1857. He was graduated at the university of North Carolina in 1832, and 3 years later was admitted to the bar in Fayetteville, where he commenced the practice of the law. In 1845 he entered public life as a member of congress from the Raleigh district, and in 1848 and again in 1850 was elected a member of the North Carolina house of commons, on the latter occasion serving in the capacity of speaker. In 1852 he was a delegate to the Baltimore convention which nominated Mr. Pierce for the presidency, and in the same year he was

again a member of the state legislature and an unsuccessful candidate for the office of U. S. senator from North Carolina. Upon the inauguration of President Pierce in 1853 he received the appointment of secretary of the navy, which he retained until the close of the administration.

DOBELL, Sydney, an English poet, born at Peckham Rye, near London, in 1824. In 1835 his father, a wine merchant in London, removed his business to Cheltenham, and at this place, or at a country house in the neighboring valley of Charlton Kings, young Dobell lived until his marriage in 1844. It is said that he fell in love at 10, became engaged at 15, and was married at 20. At the age of 12 his education, which had been conducted entirely at home, was completed, and he entered the counting room of his father, with whom he remained in the capacity of a clerk for 15 years. While thus employed he devoted his leisure hours to literary pursuits, and in 1850 produced, under the *nom de plume* of "Sydney Yendys," which he retained for several years, his poem of the "Roman." This and "Balder," which appeared 4 years later, found many admirers, who hailed the author as the originator of a new era in English poetry. The 2 poems were, however, subjected to much severe criticism, and the latter of them was travestied by Mr. Aytoun in his "Firmilian." In 1855 Mr. Dobell published, in connection with Alexander Smith, a volume of "Sonnets on the War," and in the succeeding year another volume of poems entitled "England in time of War," in which his peculiarities of rhythm, language, and thought are fully developed.

DOBREE, Peter Paul, an English scholar, and professor of Greek in the university of Cambridge, born in Guernsey in 1782, died Sept. 24, 1825. After the death of Porson he was intrusted with the task of editing a part of his notes, and published in 1820 all that Porson had left upon Aristophanes, together with learned notes by himself. In 1823 he was appointed regius professor of Greek, and at the time of his death was preparing an edition of Demosthenes, and writing a course of lectures on Greek literature.

DÖBRENTEY, Gábor, a Hungarian author, born at Nagy-Szöllös in 1786, died in 1851. He studied philology and history at Wittenberg and Leipsic; in 1810 established the "Transylvania Museum," a periodical which exercised so considerable an influence upon the development of the Hungarian language and literature that no Hungarian library is thought complete without it. In 1820 he removed to Pesth, where he continued subsequently to reside, actively engaged in literary labors, while also holding various civil offices. In 1822 he was one of 22 savants invited to assemble at Buda to devise a plan and constitution for the Hungarian academy, and in 1831 was appointed a member and secretary of that body. During the same time he was engaged upon the great work of his life, the "Ancient Monuments of the Hungarian Language." Four volumes of this were published during his life, and a 5th was left by him nearly completed. He also wrote several biographical sketches of old Hungarian authors. His poems consist of odes, epigrams, and elegies; he also translated Shakespeare's Macbeth, Molière's *Avare*, and several tragedies of Schiller, into Hungarian.

DOBRIZHOFFER, Martin, a Jesuit missionary, born at Gratz, in Styria, in 1717, died in Vienna in 1791. He passed 18 years among the Indians inhabiting the W. bank of the Paraguay river, South America, and the interior of Paraguay. When the Jesuits were expelled from the Spanish colonies he went to Vienna, where he enjoyed the favor of Maria Theresa. His principal work is a history in Latin of the Abiponians (Vienna, 1784), of which a German translation appeared in Pesth in the same year, and an English translation in London in 1822.

DOBRODJA, a district in European Turkey, on the right side of the Danube, extending from Silistria and Varna to the mouth of that river, offering the most accessible route from the north for armies to reach Constantinople. The Russians commenced here their operations against Turkey in 1828; and again in 1854, after having crossed the Danube at Braila and Galatz, they gained an important advantage by securing Matshin, one of the principal towns of the district. The Dobrodja belonged to Russia after 1829, was restored to Turkey by the treaty of peace of 1856, and now forms a part of the eyalet of Silistria, and is the most S. E. portion of Bulgaria. The population consists of 16,000 to 20,000 families of various eastern and northern tribes, who support themselves chiefly by the raising of cattle and bees, by the manufacture of salt, and by fisheries. The soil is but little cultivated, and the district is, at most seasons, a wilderness. The scanty herbage dries up early in the summer, and the flocks of sheep and herds of buffaloes repair to the borders of the Danube for pasture.

DOBROVSKY, Jozef, a Slavic scholar, born near Raab, Hungary, Aug. 17, 1753, died in Brünn, Moravia, Jan. 6, 1829. He early applied himself to the study of the German language, and acquired afterward still greater knowledge of that of Bohemia, of which country his father was a native. Previous to attending the university of Prague, he had studied at a neighboring college of Jesuits, and after having become, in Oct. 1772, a member of that order in Brünn, he devoted himself from the time of its dissolution, in Aug. 1773, to literature generally, without, however, neglecting the study of theology, which he continued to pursue at Prague. Having made his début in literature in 1778 by a critical work which attracted much attention, he increased his reputation by conducting from 1780 to 1787 a journal devoted to Bohemian and Moravian literature. He achieved most abiding fame, however, by his subsequent works on the Slavic languages and history, which gained for him the reputation of having

laid the foundation of Slavic philology. The most celebrated of them is his *Institutiones Linguæ Slavicæ Dialecti veteris* (Vienna, 1822). In 1792 and 1794 he visited Sweden, Russia, and western Europe, for the purpose of collecting documents bearing upon Slavic history. On his return he was for several years afflicted with insanity, brought about by the intensity of his labors. He recovered his health, however, in 1803. An account of his life and writings was published by Palacky at Prague in 1838.

DOBSON, Thomas, a bookseller and author of Philadelphia, died March 8, 1823. He republished the "Encyclopædia Britannica" (21 vols. 4to., including the supplement, 1798–1803), and wrote "Letters on the Character of the Deity and the Moral State of Man" (2 vols. 12mo., 1807).

DOBSON, William, an English painter, born in London in 1610, died in 1646. He served an apprenticeship with a picture dealer, and availed himself of the opportunity thus offered him to copy some of the works of Titian and Vandyke. One of his pictures fell by chance under the eye of Vandyke, who was so much struck by its merit that he presented the painter to Charles I., who sat to Dobson for his picture, and upon the death of Vandyke conferred upon him the title of his chief painter. Several of his pictures are in the cabinet of the duke of Northumberland.

DOCE, a river of Brazil, rising in the province of Minas Geraes, and entering the Atlantic in lat. 19° 36′ S.; length, 330 m., or, including windings, about 500. For about half its course it flows N., then turns nearly E., intersecting the province of Espiritu Santo, and is bordered by a rich, beautiful, but much neglected country. Its navigation is greatly impeded by numerous cataracts.

DOCETÆ, in the primitive church, the partisans of those doctrines which admitted the appearance but denied the reality of the human form and nature of Jesus Christ. Those who looked upon matter as essentially evil, a view derived from a perverted Platonism or from oriental theories, were offended at the idea of a revelation of Deity through sensible objects. Accordingly they declared that every thing corporeal in Christ was only in appearance, and for the manifestation of the spirit, and that his life was merely a continued theophany. It was probably against Docetic errors, which had appeared even in the time of the apostles, that some passages in the gospel and epistles of St. John were directed. Docetism, of which there were various forms, was itself a form of Gnosticism, and its teachers, as Valentinus and Bardesanes, are reckoned among the Gnostics. It was thought by its believers to reconcile the narrative of the Gospels with the respect due to the Deity, in maintaining that the sufferings and death of Christ were only apparent.

DOCHART, a lake in the parish of Killin, Perthshire, Scotland. Its banks are clothed with groves of remarkable beauty; it contains a curious floating island, and another small isle on which stand the ruins of an ancient castle. The lake is about 3 m. long, and has its outlet through a river of the same name, which waters Glen-Dochart and falls into the Lochy.

DOCIMASIA (Gr. δοκιμασια, trial), in ancient Athens, a scrutiny into the life and conduct of any person chosen to hold a public office. Archons, senators, generals, and other magistrates were exposed to this scrutiny, which was conducted by selected persons. The examination for the archonship was intrusted to the senators themselves. The docimasia was not limited to candidates for public offices, but a scrutiny might be denounced against any orator or other eminent person who had been accused of flagitious crime; and he was then obliged to prove his innocence before a court of justice, or suffer disgrace and exclusion from the assemblies.

DOCK, an artificial basin for the reception of ships, either for their security or for the purpose of building, repairing, or examining them. Docks are of 2 sorts, wet and dry. The former are usually constructed with gates to retain the water. Ships are admitted at high water, and kept afloat by closing the gates. Basins are wet docks without gates, the water ebbing and flowing with the tide. Dry docks sometimes become dry by the ebbing of the tide, but are usually pumped out by the steam engine; they are closed by gates carefully constructed to prevent the ingress of the water. The most common form for this purpose is that of swinging gates, opening in the middle like the lock gates of a canal. The floating gate or caisson is a vessel with keel and stem, constructed to fit grooves in the masonry at the entrance of the dock; water being admitted into this vessel, it sinks in the grooves, forming a closed gate; it is removed from its place by pumping out water sufficient to float it clear of the grooves. These caissons are more cheaply constructed than swinging gates, occupy less space, are more easily repaired, and the same caisson may be used at different times for different docks.—Wet docks have proved a very important auxiliary to navigation and commerce. By their means vessels are more safely moored and protected against winds, tides, and currents, and, with suitable police regulations, are less liable to fire, robbery, &c. Wet docks also effect a great saving in the time and expense of loading and unloading vessels. The principal docks on the Thames are the East and West India docks, the London docks, the St. Katherine's, the Commercial, and the Victoria docks. The West India docks were commenced in Feb. 1800, and opened in Aug. 1802. They stretch across the isthmus joining the Isle of Dogs to the Middlesex side of the Thames, and consisted originally of an import and export dock, each of which communicated by means of locks with a basin of 5 or 6 acres in extent at the end next Blackwall, and with another of more than 2 acres at the end next Limehouse, both of these basins in turn communicating with the Thames. The south dock, which runs parallel to the ex-

port dock, was added in 1829. The export dock, appropriated to ships loading outward, is about 870 yards in length by 135 in width, covering an area of nearly 25 acres. The import dock, appropriated to ships entering to discharge, is as long as the export dock, and 166 yards wide; its extent is nearly 30 acres. The south dock is 1,183 yards long, and is used indiscriminately for vessels either loading or discharging; it has an entrance to the river at each end. At the highest tides the depth of water in the docks is 24 feet, and the whole will readily contain 600 vessels of from 250 to 500 tons. The import and export docks are parallel to each other, and divided by a range of warehouses which are chiefly used for the reception of spirituous liquors; smaller warehouses and sheds on the quays of the export and south docks are used to receive goods sent down for exportation, while the warehouses for imported goods are on the 4 quays of the import dock. An idea may be formed of the extent of these docks, when it is stated that there have been deposited at the same time upon the quays, under the sheds, and in the warehouses, 148,563 hhds. of sugar, 70,875 casks and 433,648 bags of coffee, 35,158 puncheons of rum and pipes of Madeira wine, 14,021 logs of mahogany, 21,350 tons of logwood, &c. The whole area occupied is about 295 acres; the establishment is surrounded with a high wall, and so strict are the precautions against fire and pilfering, that as soon as a ship enters the docks the crew is discharged, and no person whatever is allowed to remain on board or within the premises, the gates of which are shut at a certain hour. In almost all docks a serious evil is felt from the accumulation of mud and consequent diminution in depth of the water, and scouring and dredging have been deemed the only relief; but in the West India docks the evil has been obviated. The water of the Thames is very muddy, and when admitted in large quantities to repair the loss caused by evaporation, leakage, lockage, &c., the deposit is very considerable; the loss or waste of water from the docks was found to be upon an average equal to 5 inches in depth over the entire surface every 24 hours, and not only was this loss to be supplied, but it was necessary that the water in the docks and basins should be kept up to a point higher than that of the highest spring tides, since all the gates of the locks point inward, to sustain the water of the docks. To supply this want, the company have constructed 3 reservoirs, 2 of which are filled from the river by a culvert with sluices; the water is then allowed to settle, and afterward pumped by an engine into an elevated reservoir, from which the docks are constantly supplied with clear water. This establishment was formed by subscription, and the property vested in the West India company, the affairs of which were managed by 21 directors. All West India ships frequenting the Thames were obliged to use them for a period of 20 years from their completion. The dividends were limited by the act of incorporation to 10 per cent. So successful was the company that in 1819 a surplus fund of nearly £400,000 had been accumulated; but having reduced their charges very materially, the surplus has been absorbed. The engineer of these docks was William Jessop, and the total expense of their erection was about £1,500,000.—The East India docks at Blackwall were originally intended only to accommodate vessels engaged in the East India trade, but are now open to vessels from all parts. There are 2 docks, the import dock containing about 18 acres, and the export dock about 9 acres. The entrance basin connecting the docks with the river contains about 2¾ acres; the length of the entrance lock is 210 feet, and the width of the gates 48 feet clear. The depth of water in the docks is never less than 23 feet, and there is attached to them a quay fronting the river nearly 700 feet in length. Both these and the West India docks are now under the control of the East and West India dock company, the union having been effected in 1838. The capital of this company amounts to over £2,000,000, and the management is vested in a board of 32 directors.—The London docks are situated in Wapping, and were principally intended to receive ships laden with wine, brandy, tobacco, and rice. They were begun in 1800, and opened in Feb. 1805. The western dock is 20 acres in extent, and the new or eastern dock about 7. The tobacco dock, which lies between, and is appropriated solely to tobacco ships, exceeds one acre in extent. On the north side of this dock is the great tobacco warehouse, a building which occupies under one roof between 4 and 5 acres of ground. It is said to be capable of containing 25,000 hhds. of tobacco, while the vaults underneath will accommodate as many pipes of wine. All ships bound for the Thames, laden with wine, brandy, tobacco, or rice (except ships from the East and West Indies), were obliged to unload in these docks for 21 years; this monopoly expired in 1826, and the use of the docks is now optional. The entrances were formerly by the basins at Wapping and Hermitage, but another entrance was completed a few years ago from old Shadwell dock to the eastern dock. The stock of the company amounts to nearly £4,000,000, a considerable portion of which was required to purchase the houses, some 1,300 in number, that occupied the site of the docks. The board of directors consists of 25 members, the mayor of the city of London, as conservator of the river Thames, being one. Two new docks have been recently constructed at the London docks (200 and 150 feet long respectively, 60 feet wide; depth of water 28 feet), as well as a new basin, 780 feet by 450 feet, and extensive warehouses.—St. Katherine's docks, situated immediately below the tower, were executed in a year and a half, and first opened Oct. 25, 1828. The entire property covers an extent of 24 acres, 11 of which are occupied by the 2 docks, which communicate by a basin. The entrance lock is 180 feet long and 45 broad, and ships of over 800

tons register are docked and undocked with facility. The warehouses are very commodious, and being built close to the water's edge, goods can be transferred to them directly from the hold of the vessel, without a preliminary landing on quays, as in the docks before mentioned, thus effecting a great economy of time and labor. —The Commercial docks are on the opposite side of the river, and existed in 1660 under the name of the Howland great wet dock, and subsequently of the Greenland docks, having been prepared for the express purpose of accommodating Greenland whaling vessels. In 1807 they were greatly enlarged, and received their present name. They are used chiefly to receive vessels laden with corn, iron, lumber, guano, and other bulky commodities. They cover an area of 120 acres, 70 of which are water. The granaries will contain 140,000 quarters of corn. A new dock at the Commercial docks was opened in 1855.—The Victoria docks are situated on the Plaistow marshes, on the N. side of the Thames, immediately below the East and West India docks. The company own 200 acres, 74 of which are occupied by the dock, which affords 23½ feet depth of water. The entrance into the Thames is at Bow creek, by a lock 300 feet long and 80 feet wide. There is also a half-tide basin of 16 acres, and 5 jetties with warehouses containing over 11 acres of warehouse floor. The company own in addition an acre and a half, between Thames street and the river, on which to erect warehouses. These docks were completed in 1855. The lock gates, cranes, and capstans are all worked by hydraulic power. A special object of the company is, by the construction of a collier dock, to withdraw from the Thames a portion of the coal trade of the port, thus relieving the traffic on the river from serious obstruction, and extending greater facilities of discharge to the colliers.—The Southampton dock company was incorporated in 1836, and have at present built 2 wet docks, one an open dock of 16 acres, and with a depth of 18 feet at low water, and the second a close dock (the first of an intended series of 3), with an area of 10 acres, and a permanent average water depth of 23 feet. Both docks are surrounded by extensive bonded warehouses, vaults, sheds, &c. Attached to the wet docks are 3 dry docks, the largest of which is 450 feet in length, with 80 feet gates and 25 feet depth of water. At the Grand Surrey dock, a new dock entrance, inner dock, basin, and timber dock are in course of formation (1859), and are estimated to cost upward of £100,000. Extensive docks have also been formed at Brentford in connection with the canal terminus and the Great Western railway.—The Liverpool docks are very numerous, and have greatly contributed to the growth and consequence of the port. The first dock, constructed in 1715, had an area of 3¼ acres. It was filled up in 1826, in order to erect the custom house on its site. Between 1830 and 1852 no fewer than 22 docks and basins were opened; the total water space is about 200 acres, and the entire dock estate 712 acres. The Huskisson dock, constructed in Liverpool between 1852 and 1859 for the accommodation of ocean steamships, is one of the largest in the world. The width of the E. lock gates is 80 feet, of the W. lock gates 70 feet, and the water area is about 14 acres, with quay space to the extent of 1,122 yards. The docks all extend along and parallel with the river, and the river wall is 5 miles 200 yards long, while the quays measure 14 miles in length. The dock estate is managed by a committee of 24, who have charge of all the docks. The warehouses do not generally belong to the dock estate, but are mostly private property. Many are at a considerable distance from the quays, and the inconvenience arising from this arrangement has lately induced the construction of warehouses around the Albert and Stanley dock, and they are also to be built around the new Wapping dock. The docks at Birkenhead, on the west side of the Mersey and directly opposite Liverpool, were commenced in 1844, and the first, called the Morpeth dock, was opened by Lord Morpeth (the present earl of Carlisle), April 5, 1847; it communicates on the S. E. with a tidal basin of 16 acres for coasters. The Wallasey pool is to form a wet basin or float of 150 acres, and the total dock accommodation is intended to be over 200 acres. The first warehouses of the Birkenhead warehouse dock company were opened in April, 1847, and are capable of stowing away 80,000 tons of goods. Within the last few years the works have been renewed at Birkenhead on a large scale, and a considerable extension has been commenced (1859) in the docks of Liverpool. In 1857 a vast floating stage was constructed under the direction of Sir W. Cubitt, at a cost of £140,000, and moored in its place at Prince's pier. It is 100 feet long by 82 feet wide, and weighs upward of 3,000 tons; it is supported on 63 air-tight rectangular pontoons, of which 12 are each 96 feet long, 12 feet wide, and 5 feet deep; 49 each 80 feet long, 10 broad, and 5 deep, and 3 of somewhat smaller size.—At Newport a new dock (950 feet by 350 in the widest part; area 8 acres; cost £64,000) was opened in March, 1858. Docks covering an area of 13 acres were begun at Swansea in 1853. Extensive works were also in progress in the docks of Southampton and of other places in the same year. Hull has 5 docks, which occupy with their basins a water area of 49¼ acres. At Dundee there are 2 wet docks, viz.: King William's of 6¼ acres, and Earl Grey's of 5¼ acres; the breadth of the lock of the former is 40 feet, and of the latter 55. A wet dock of 14½ acres is now being constructed, with a lock of 60 feet, and an additional dock of 11 acres is projected; there is also a fine dry dock in connection with the King William dock. Leith, the port of Edinburgh, has 3 wet docks, which furnish a water area of about 15 acres. The Bute dock was constructed by the marquis of Bute at Cardiff, between 1834 and 1839, at an expense of £300,000; it contains a water space of about 20 acres, and the main entrance lock is

152 feet long and 36 feet wide. A new graving dock was constructed at Cardiff in 1858, as well as other works in connection with the Bute docks.—At Havre there are 3 old docks or basins, which can accommodate 200 to 300 vessels; a fourth, the *bassin de Vauban*, situated outside the walls, is larger than any of the others, and furnished with warehouses of the best construction; it was completed in 1842. A fifth dock has also recently been constructed for steamers. The harbor of Marseilles is a basin in the centre of the city, 1,050 yards in length by about 300 in breadth; the depth of water ranges from 12 to 24 feet, and dredging machines are kept constantly at work to clear out the mud, and prevent the basin from filling up. Three extensive basins were constructed at Antwerp in 1803; these are sufficiently deep to admit vessels of large size, which are enabled to penetrate the heart of the city by means of 8 canals. The docks at Cherbourg were commenced by Napoleon I., and the first basin was opened in Aug. 1813; the work was completed and the last basin opened in Aug. 1858. (See CHERBOURG.) The dry docks at Sebastopol, which were mainly destroyed after the capture of the city, Sept. 8, 1855, were situated considerably above the level of the Black sea, and the expense of pumping was entirely avoided; ships were raised into a general dock basin by a series of 3 locks, each of which had a rise of 10 feet. The water for supplying the basin, for filling the docks, and for working the locks, was brought by a canal 12 miles long, which taps a mountain stream. Vessels, after being elevated into the general basin, were floated into one of these dry docks, and, the gates being closed, the water was let off into the sea, through a subterranean culvert. The Brazilian government has been engaged for several years in the construction of a dry dock, the work on which is performed by convicts. It is excavated out of the solid rock, and is to be 300 feet long, 92 feet broad, and 32 feet deep.—In the United States are to be found the finest dry docks in the world. The largest is the granite dry dock at the Brooklyn navy yard, situated on the Wallabout bay, directly opposite New York city. It was commenced in Aug. 1841, and completed in Aug. 1851. The main chamber of the dock is 286 feet long and 30 feet wide on the bottom, and 307 feet long and 98 feet wide on the top, and by using the caisson or floating gate instead of the folding gates an additional length of 52 feet may be obtained; the least width is at the hollow quoins, where the walls are 66 feet apart at mean high water line; the least depth of the dock is over the mitre sills, where there is 26 feet of water at mean high tide; the whole height of the walls is 36 feet. The caisson is an iron vessel 66 feet long, 16 feet beam, and 30 feet hold; it is used in case the turning gates require repair, or to relieve the strain on them by dividing the pressure of the water. The pumping engines are sufficiently powerful to empty the dock in about 2 hours 10 minutes, the amount of water pumped out in that time being 610,000 gallons. When a ship is to be docked, the filling culverts are closed, as well as the passages from the dock chamber to the draining culverts leading to the pump well, and the water is pumped from the latter; the ship is then admitted and placed over the keel block in the centre of the dock; the caisson is next floated to its place, over the recess or groove, and filled with water until it sinks down to the bottom of the masonry fitted to receive its keel; after which the turning gates are closed by men standing on the bridge, and working the 4 hand wheels that move the machinery. The culvert gates in the dock chamber are next drawn and the water allowed to flow into the draining culvert and well, by which means the water is lowered several inches in the dock in a few minutes, thus hastening the shoring and producing an immediate pressure on the gates, so as to effectually prevent the admission of water and fix them steadily. A complete command of the level at the moment the gates are closed, or when a ship, especially a large one, is about to touch the blocks and requires the placing of shores, is important; and the above method gives a more perfect control of the operation for the first foot than could be obtained by the best regulated pumps and machinery for driving them. The water remaining in the dock is afterward pumped out of the well into the reservoir, from which it is discharged into the culvert leading to the bay, the ship being continually shored up, as the process of emptying is carried on.—There are also numerous floating dry docks at New York, owned and controlled by private companies; the principal of these are the balance docks, the floating sectional docks, and the hydrostatic screw dock. The balance dock, patented by Gilbert, combines the principles of the caisson and the camel, united together in a walled dock, in the middle compartment of which the vessel rests after the water is pumped out; the side compartments or balancing chambers butt into a caisson, the inner walls of the chambers being sloped, and the entire structure strongly braced and trussed, both transversely and longitudinally. It received the name of balance dock from the facility of preserving an exact equilibrium and level by means of water let into or pumped out of the separate compartments of either of the side chambers, all of which communicate with the pump well by means of valves. The New York balance dock company own 2 of these docks, the smaller one being 210 feet long, 70 feet wide, and 30 feet deep; while the larger one is 325 feet long, 100 feet broad, and 40 feet deep. The lifting power of this large dock is 8,000 tons, and it is worked by 2 steam engines of 100 horse power each, setting in motion 14 pumps, each 40 inches in diameter and 5 feet stroke. As an instance of its power, it may be mentioned that the Russian frigate General Admiral, an immense vessel of 6,000 tons burden, and weighing 3,680 tons, was taken up on this dock, Nov. 20, 1858, in the

space of 1½ hours. Docks of this description are now in use at the Portsmouth navy yard, and at Savannah, Mobile, Charleston, and New Orleans; also at Havre and Marseilles; and the Austrian government is now building one at Trieste equal in dimensions to the larger New York dock. In docking a vessel on the balance dock, the pumps are first set in motion by the steam engines on the deck above, and the discharge opening being closed by a gate for that purpose, the water rises in the chamber above the pumps until it is full to the deck of the dock. It is next allowed to flow into the upper chamber of the dock until its weight, acting as ballast, sinks the dock to the required depth. When the ship is floated into the dock, this ballast is drawn off by means of valves, causing the dock to rise by its own specific gravity until it touches the bottom of the ship, after which the vessel is lifted by pumping the water out of the side chambers and bottom tank; and as the dock rises, the water around the ship in the middle chamber ebbs out, so that the quantity of water to be exhausted in raising a vessel is in proportion to her weight and not to her bulk.—The New York sectional floating dock company was formed in 1838, and the first dock was begun in 1839 by Messrs. Burgess and Dodge, the patentees. This form of dock derives its name from its consisting of distinct sections of timber framing, forming, as in the case of the balance dock, a floating dock into which ships can enter. In the sections on each side are balance tanks, raised and lowered by means of a rack and pinion; also tanks which by being filled with water cause the dock to sink, and by the water being pumped out enable it to be raised to any required height out of the water, the ship resting on the platform within. On the top of the section is machinery for working the racks and pinion, and pump work. The present number of sections owned by the company is 18, and they generally form 3 docks of 4, 6, and 8 sections respectively, but, according to the size of the vessel to be raised, any number of sections may be used, as convenience suggests. Each section is 92 feet broad externally, and 64 feet internally, and 23 feet long; the sections are also 38 feet high externally, exclusive of engine house, and 28 feet high internally to the top of the standards. Each section may be considered as consisting of 3 parts, viz.: 2 lateral scaffoldings, or framings of standards within which the balance tanks run, and a central platform connecting them. The process of docking is as follows: the dock is sunk to any required depth, by opening the gates or valves with which each water tank is furnished; the ship is then introduced between the vertical side framing and rests upon the keel blocks, being supported on the sides; the valve which previously admitted the water into the water tanks is then closed, and the water being pumped out the air again fills the tanks, which rise, bringing with them the vessel to the required height; by again admitting water into the tanks the vessel is undocked.—The New York screw dock company own a screw dock and a hydrostatic screw dock. In the former dock, the vessel is floated on to a timber platform, which is suspended from strong manning pieces of beams on each side, laid on the quay walls, by 8 suspending screws 4½ inches in diameter; the platform can be sunk about 10 feet below the surface of the water, to receive the vessel, which is properly shored by timbers resting on the platform. In a dock of this kind at Baltimore, the platform is suspended by 40 screws of about 5 inches in diameter. The hydrostatic screw, or lifting dock, is an improved form in which hydrostatic power is brought to bear as the lifting force; it forms a slip abutting on the shore, with a suspended keel, allowing vessels to be raised up vertically; this keel consists of 2 outer and parallel ranges of piling, each bearing a way at the top from which are suspended chains with transverse beams or swing beams slung to them, over which the vessel to be docked floats; and having arrived over this movable platform or grating, the chains are raised by a hydrostatic press and the vessel brought to the level of the permanent way. The dock is 165 feet long internally and 35 feet wide; the distance from the outside of one mainway to the outside of the other is 51 feet. The mainways abut on the land, and run about 38 feet beyond the head of the dock on to the land, resting on a solid quay of masonry, to which they are bolted down and which supports the machinery. A number of docks on this principle have been constructed by the same company.—Beside the dry docks enumerated, New York possesses a basin of considerable extent called the Atlantic basin, situated in Brooklyn, opposite Governor's island. This work was constructed by the Atlantic dock company, incorporated in 1840 with a capital of $1,000,000; the entire area occupied is about 80 acres, 42 of which form a water surface. The basin was formed by enclosing this area with piers and bulkheads; the piers are 150 feet wide; those which form the front of the basin on the stream are divided by an entrance 200 feet in width; the depth of water in a portion of the basin is equal to 25 feet at low tide. Spacious warehouses are erected on the piers and surround the basin. A somewhat similar basin was constructed at Albany, at the terminus of the Erie canal, for the accommodation of the canal boats and of the ordinary shipping. The basin, containing about 32 acres, was formed by erecting a pier 80 feet in width along the W. bank of the Hudson; this was laid out into lots 30 feet in front, with warehouses on the same 50 feet deep. The pier is connected with the main shore by drawbridges, and is accessible at all times.—In addition to the New York dry dock already mentioned, there are naval dry docks at the navy yards of Boston, Portsmouth, Philadelphia, Norfolk, Pensacola, and San Francisco, costing in the aggregate, and exclusive of the New York dock, no less than $5,000,000. The Boston dry dock is of granite; it was commenced in June, 1827, and completed in March,

1834; its location is not in Boston proper, but in Charlestown. The interior of the chamber at top is 86 feet wide and 253 feet long, to the face of the arch above the water sill, being the portion that can be used for docking vessels inside of the turning gates; in addition, however, the space between the turning and floating gates, 53 feet, can be used by blocking up to the level of the mitre sills, making the total length of the dock 306 feet. The width of the chamber floor is 30 feet, and length 228 feet; the depth from coping to mitre sill is 30 feet; depth of water at ordinary high tide over mitre, 25 feet. The dry dock at Norfolk is also granite, and is located on the southern branch of the Elizabeth river, about 1½ miles from Norfolk and adjoining Gosport. It was commenced in Nov. 1827, and completed in March, 1834. Before its completion, the ship of the line Delaware was docked in it on the anniversary of the battle of Bunker hill (June 17, 1833), being the first national ship ever docked in a dry dock of the United States. In dimensions and character it is almost precisely similar to the Boston dock, described above, having been built from the same working plans, and under the direction of the same chief engineer. The dock at the Philadelphia navy yard consists of a sectional floating dry dock of 9 sections, and a permanent stone basin, with 2 marine railways extending from one of its 3 sides. It is located upon the Delaware river. The sectional dock consists of 9 sections, 3 of which are 30 feet and the remaining 6 32 feet in width, each consisting essentially of a main tank, 2 end frames, and 2 end floats; the main tanks are each 105 feet in length, 30 or 32 feet in width, 11 feet high at the ends, and 11½ feet at the centre. There are 2 beam engines of 20 horse power, and 2 of 12 horse power, each with locomotive boilers, which move the machinery for working the 3 pumps at each end of each section, and the end floats; the 9 sections are often arranged into 2 floating docks, 2 of the engines being employed for each dock. As a general rule, the largest ships of the line and steamers may be docked upon 6 sections, while a sloop of war can be docked upon the remaining 3; or a frigate may be docked upon 5 sections, and smaller vessels upon the remaining 4. This form of dock can be readily repaired, and one section may be raised by 2 others for that purpose. The bottom of the basin is 350 feet long and 226 feet wide, and 12 feet 9 inches to the top of the side and end walls, and so constructed as to have 10 feet 9 inches of water in the basin above the floor, at mean high tide. Each marine railway consists of 3 parallel ways of white oak, the centre way being intended to sustain the weight of the vessel upon her keel, and the other 2 at equal distances from the centre way to keep the vessel steady upon her keel during the operation of sliding her on shore; there are also temporary bedways for placing upon the deck of the dock, and when used to be accurately alligned with the bedways on shore. The cradle is constructed to be placed under the keel and bilges of the vessel, to sustain her with her keel upon the centre bedway and her bilges upon the bilgeways; for the latter purpose each side of the vessel is blocked up with square blocks of timber, from the bilgeway of the cradle. This dock was commenced in Dec. 1849, and completed in June, 1851. The San Francisco dock is also a sectional floating dock, similar to that at Philadelphia, but exceeding the latter in displacement and lifting power about 10 per cent. It consists of 10 sections, each 100 feet long, 32 feet broad, and 11 feet 9 inches high, with 2 end floats to every section, each 26 feet 8 inches long, 15 feet wide, and 8 feet high. The construction of the dock was commenced in New York in June, 1851, and it was completed ready for shipment early in the spring of 1852. The dock at Portsmouth, N. H., is situated on the Piscataqua river, and consists of a balance dry dock, a stone basin, and railways. The balance dock is 350 feet long, 105 feet 4 inches broad, and 38 feet deep. The chambers on each side are 7 feet 8 inches wide, reducing the interior width to 90 feet. The basin is 360 feet long, and 120 feet wide on the bottom, the walls 14 feet high, battening back 3 feet on all sides, from the bottom to the top of the basin. The railways are similar in character and dimensions to those at the Philadelphia navy yard. The dock was contracted for on Nov. 11, 1848, and completed in Nov. 1851. The dock at Pensacola consists of a balance dock, basin, and marine railways. The balance dock is precisely similar to that at Portsmouth, except that it is provided with extra fixtures to steady vessels, when used as a camel for carrying them over the bar of the bay. The railways are the same as those constructed for the Philadelphia dock.—For a description of the government dock yards of Great Britain, see Chatham, Deptford, Devonport, Portsmouth, Sheerness, Woolwich, &c.

DOCTOR (Lat. *doceo*, to teach), a person who has taken all the degrees of a faculty, and is empowered to teach and practise it. It is bestowed by universities and colleges as an honorary distinction. The doctorate and the degrees which conduct to it were first instituted early in the 12th century. The first ceremonious installation of a doctor was at the university of Bologna, when Bulgarus was promoted to the doctorate of the civil and canon law. The learned Irnerius, one of the revivers of the Roman law at that time, composed the formulary which has been followed since, and which gives great solemnity to the reception of the degree. The usage was immediately adopted by the university of Paris, which in 1145 conferred the degree of doctor upon Peter Lombard and Gilbert de la Porrée, two of the most eminent theologians of that period. According to another tradition, the title was first applied to those teachers who explained to their scholars Lombard's "Book of Sentences," which was not published till 1140. It was at that time substituted for the title of master, which had grown too com-

mon and familiar. The title and degree of doctor were in use in England under King John, about 1207. In Germany during the middle ages a doctor of law enjoyed the same privileges as knights and prelates. The first doctors were only of law and theology; medicine was afterward added; and in 1340 in the university of Paris the 4 faculties of law, theology, medicine, and the arts or letters, were organized as they are now. At Oxford and Cambridge, and recently also in some of the German and American universities, diplomas of doctor of music have been given. The title of doctor has occasionally been bestowed upon women. In 1787 the university of Göttingen decreed the title of doctor of philosophy to Dorothea Schlözer; in 1817 the university of Giessen gave the title of doctor of medicine to Mariane Charlotte von Siebold; in 1827 the university of Marburg pronounced Johanna Wyttenbach doctor of philosophy. Still more recently several young women have received the title of doctor of medicine from foreign and from American schools. The comic authors of the last century show that the title of doctor had even then fallen into discredit and was a common theme for ridicule. In a French dictionary of that era, under the word "forget," was found the following explanation: "A bachelor is a man who learns; a doctor is a man who forgets." In the universities of Oxford and Cambridge, and in most of the European universities, a student who is to receive the degree of doctor has to prepare one or more theses, which in Germany are called the inaugural theses. In the United States the title is conferred upon those of eminent learning or ability in their profession, without demanding from them any learned exercise in return; excepting in the medical profession, where it is bestowed at the end of a course of study. The title had an existence outside of the universities during the middle ages, and was bestowed upon every one of singular learning. Thus Alexander Hales was called the irrefragable doctor; Thomas Aquinas, the angelic doctor; Bonaventura, the seraphic doctor; Duns Scotus, the subtle doctor; Roger Bacon, the admirable doctor; William Occam, the singular doctor; Denys le Chartreux, the ecstatic doctor; and Alain de Lille, the universal doctor. The title of doctor has been given to some of the fathers of the church whose teachings have the highest authority. At an early period there were accounted 4 doctors of the Greek church, St. Athanasius, St. Basil, St. Gregory Nazianzen, and St. Chrysostom; and also of the Latin church, St. Augustine, St. Jerome, St. Gregory the Great, and St. Ambrose. Pope Pius V. assigned the 5th place among the Latin doctors to St. Thomas Aquinas, and Sixtus V. gave the 6th place to St. Bonaventura. St. Bernard was added to the series by Pius VIII. The title of doctor of the law existed among the ancient Jews. Those who figure in the Talmud are called doctors of the Talmud, or distinctively doctors of the Mishna and of the Gemara, according to the division of that book in which they appear. They were also called rabbis, a title bestowed also on Jewish scholars of a later period. These, however, are not called doctors. The Jewish doctors were invested with the dignity by receiving into their hands a key and a tablet book. The key was the symbol of the science shut up in the heart, which the doctor was to open to impart to his disciples.

DOCTORS' COMMONS, the college of civilians in London, near St. Paul's churchyard, founded by Dr. Henry Harvey, dean of the arches, for the doctors of the civil law, burned down in the great fire of 1666, and rebuilt in 1672, at the cost of the profession. In the common hall were held until 1858 the sessions of: 1, the court of arches, the chief ecclesiastical court of the province; 2, the prerogative court, for the trial of testamentary causes; 3, the consistory court of the bishops of London; 4, the court of admiralty. The most interesting part of doctors' commons was the prerogative will office, in which were kept all wills admitted to probate in the prerogative court of the archbishop of Canterbury, which had jurisdiction over nearly all such business in the kingdom. The original testaments preserved here dated from 1483; the copies from 1383. Great care was taken to prevent mutilation. No stranger was allowed to make a memorandum from either the wills or the index; extracts or transcripts, when wanted, were written out by the attending copyists, but any person was allowed to examine a will on payment of the regular fee. Attached to the college there were 34 proctors, who gave licenses for marriages, and performed the duties of solicitors. Only doctors of the civil law, however, were allowed to practise in the courts held in doctors' commons. By acts of parliament passed Aug. 25 and 28, 1857, and Aug. 2, 1858, the importance of doctors' commons was for ever destroyed. Jurisdiction in all testamentary, divorce, and matrimonial cases was transferred from the ecclesiastical tribunals to a court of probate, and a court for divorce and matrimonial causes. A central office for the registry of wills was opened with branches in the chief towns of the kingdom, and judges of ecclesiastical courts were ordered to transmit to it all wills in their possession. Serjeants and barristers at law were admitted to practise in the probate court, but compensation was made to the displaced proctors to the amount of ¾ the average profits of their business, payable during their natural lives, and officers of the ecclesiastical courts were transferred to corresponding positions in the new probate court. Marriage licenses were to be granted as before. The same restrictions relative to the examining of wills continue in force in the new registry office, and drew forth a remonstrance from literary men early in 1859.

DOCTRINAIRES, a French constitutionalist party, which originated after the restoration of the Bourbons, and represented the interests of liberalism and progress as opposed to the ultra royalists in the executive government and legis-

lature. Camille Jordan, Decazes, Royer-Collard, and Guizot were leaders of this party. They were called *doctrinaires* because they insisted that the state should be administered in accordance with the abstract doctrine of right, rather than with the mere expediency and passion of the hour. After the revolution of July, 1830, when they came into power, they assumed a conservative position in antagonism with the republicans and radicals, who then came upon the stage. After the revolution of Feb. 1848, the *doctrinaires* were no more heard of.

DOD, Albert Baldwin, D.D., an American scholar, born in Mendham, N. J., March 24, 1805, died in Princeton, Nov. 20, 1845. He was of a family remarkable for mathematical talent, his father being an eminent mechanician. He was graduated at Princeton college in 1822, and, after having spent more than 3 years in private teaching in Fredericksburg, returned to Princeton in 1826 as a student in the theological seminary. In the following year he accepted a tutorship in the college, which he retained till 1829, being in the mean time licensed to preach by the presbytery of New York. In 1830 he was elected professor of mathematics in the college, and continued in this position till his death. In addition to his official duties he lectured upon architecture and political economy, and wrote occasional review articles, especially for the "Biblical Repertory," to which he was one of the favorite contributors. An article written by him on capital punishment, and in answer to objections urged against it, was adopted by a committee of the New York legislature as their report. His talent lay in the clearness and vivacity of his intellect, and was best exhibited in philosophical discussion. He therefore excelled as a preacher and lecturer, and especially in conversation. He declined an invitation to the chaplaincy and professorship of moral philosophy in the military academy at West Point.—Daniel, an American machinist, father of the preceding, born in Virginia, Sept. 28, 1788, died in New York, May 9, 1823. His father was distinguished for his versatile mechanical genius, and after having taken part in the war of the revolution, labored alternately as blacksmith, gunsmith, silversmith, land surveyor, and manufacturer of mathematical instruments. Daniel received a thorough scientific education, and declined an appointment as professor of mathematics in Rutgers college to devote himself to the manufacture of steam engines for steamboats, then a new invention. He established himself at Elizabethtown, N. J., and built for the steamboat Seahorse an engine of different construction from any that had preceded it; but it proved to be superior to all former ones, was generally adopted, and has continued without much modification the usual model of the steam engine until the present time. In 1818 he built an engine for the steamship Savannah, which the next year made the first voyage across the Atlantic ever performed by a steamship, and returned in safety after visiting England and Russia. The experiment was, however, pecuniarily unprofitable, and was not immediately repeated. Mr. Dod removed in 1821 to New York city, where he continued his employment, and was reputed the most successful engine builder in the United States. In 1823, after having altered the machinery of a steamboat, he went on board of her to witness in a trial trip on the East river the effect of his changes. The boiler of the engine exploded, so severely injuring Mr. Dod that he survived the calamity but a few days.

DOD, Charles Roger, an English journalist, born May 8, 1793, died Feb. 21, 1855. He was educated for the legal profession, but began early to write for periodicals, and in 1832 became connected with the London "Times." He had under his care the biographical department of that paper, and the reports of parliamentary debates. He also edited the "Parliamentary Pocket Companion," and the "Manual of the Peerage, Baronetage, and Knightage" of Great Britain.

DODD, Ralph, an English engineer, born in Cheltenham in 1756, died April 11, 1822. He first studied drawing at the schools of the royal academy, but abandoned this pursuit to follow his genius as a civil engineer. In 1798 he published in London plans for several public works, some of which were carried into effect. Among these were schemes for tunnelling the Thames, for a canal from Gravesend to Chatham, for the East London water works, and for a bridge at Vauxhall. He obtained a patent for a steamboat on the Thames between London and Gravesend, but the project was not carried out. He was seriously injured by the explosion of the boiler of a steam packet at Gloucester, and though he languished for some time after it, he never recovered. Beside the plans above mentioned, he published an "Account of the Principal Canals in the Known World, with Reflections on the Utility of Canals" (8vo., 1795); "Reports, with Plans and Sections, of the proposed Dry Tunnel from Gravesend to Tilbury" (4to., 1798); and "Letters on the Improvement of the Port of London, demonstrating its practicability without Wet Docks" (1799).

DODD, William, an English clergyman, celebrated for his talents, his follies, and his misfortunes, born at Bourne, Lincolnshire, in May, 1729, executed in London, June 27, 1777. He studied at the university of Cambridge, where he displayed rare talents, and at an early age distinguished himself as a writer both of prose and poetry. He left Cambridge for London in 1750, and the next year married a young lady who possessed neither virtue nor fortune, and whose tastes were even more extravagant than his own. He was ordained deacon the same year, and priest in 1753, and was appointed to the vicarage of West Ham, near London, where he obtained great success by the amiability of his character and his impressive eloquence. His reputation so increased that he was quickly called to London as a preacher, at the same time retaining

his former benefice. He now abandoned himself to extravagance and excesses. In the hope of being able to meet his increasing expenses, he multiplied his labors as editor and author, and in the course of several years published various original pieces, translations, and new editions of esteemed works. He was intrusted in 1763 with the care of the education of Philip Stanhope, afterward earl of Chesterfield, and obtained from his patrons an appointment as one of the chaplains of the king. In 1766 he took the degree of doctor of laws at Cambridge. His dissipations increased with his income, and though he drew a lottery prize, and received numerous salaries and the income from several benefices, he did not succeed in improving his financial condition. Pursued by his creditors, and ambitious of a still higher position than he had yet obtained, he ventured to write to the wife of the lord chancellor an anonymous letter, offering her £3,000 if by her influence he might be promoted to the rectory of St. George, Hanover square. This letter, being communicated to the chancellor, laid before the king, and traced to the author, caused his name to be stricken from the list of the royal chaplains. The scandals of his past life then became a theme of public remark and ridicule, and he fled from England to Geneva, where his pupil, the young Lord Chesterfield, was then residing. The latter, taking into consideration the painful situation of his former instructor, gave him a sum of money to satisfy his creditors, and presented him to a living in Buckinghamshire. But Dodd was incorrigible, and went directly with his money to France, where he spent it in an unecclesiastical manner, at one time appearing in a phaëton at the races at Sablons, near Paris, dressed like a Parisian sportsman. On his return to England in 1776 he resumed with gravity his pastoral functions, and preached with a fluency and unction worthy of a purer reputation. His last sermon was at the Magdalen chapel, Feb. 2, 1777. Two days after this he forged a bond upon his late pupil, Lord Chesterfield, for £4,200, on which he borrowed money. The fraud was discovered before the criminal had time for flight. He was imprisoned, tried at the Old Bailey, and condemned to death. Though recommended by the jury to the royal clemency, and though numerous noble protectors, many clergymen, and a petition from the city of London bearing 23,000 signatures, prayed for the interference of the crown, he was executed at Tyburn. Of the many writings of this strange moralist, the "Thoughts in Prison," a poem in blank verse, written during the progress of his trial, and his "Reflections on Death," are the only ones which are not now forgotten.

DODDRIDGE, a N. W. co. of Va., drained by Hughes river; area, about 300 sq. m.; pop. in 1850, 2,750, of whom 31 were slaves. The land is mostly hilly and adapted to pasturage, but Indian corn and oats are also raised in considerable quantities, and lumber is exported. In 1850 the productions were 59,423 bushels of Indian corn, 13,398 of oats, 1,860 tons of hay, and 35,200 lbs. of butter. The county contained one church, and there were 115 pupils attending public schools. Value of real estate in 1856, $742,306. Capital, West Union.

DODDRIDGE, Philip, an American lawyer and politician, born in Brooke co., Va., in 1772, died in Washington, Nov. 19, 1832. His family were associated with the pioneer settlements on the Ohio river, and as a boy he worked with his own hands at the plough. But failing in health in consequence of severe physical exertion, he was placed at school when 16 years of age, and made rapid progress in his studies. A too close application to his books having rendered it necessary for him to intermit his educational pursuits, and having been invited to join two or three young men of his own age, who were going to New Orleans with produce, he embarked in a flat-boat, and floated down the Ohio and Mississippi. On reaching Natchez, then in the possession of the Spaniards, the young boatmen found the place under strict police regulations, which forbade the admission of strangers into the town; but Doddridge determined to take a walk around the environs, and actually began to ascend the hill. Here he was met by an officer who addressed him in Spanish. Doddridge replied in Latin, and the Spaniard, who proved to be the governor of the post, was so much struck with the learning manifested by a boy engaged in the management of an Ohio flat-boat, that he invited him to dine, and upon his departure gave him letters of introduction which admitted him into society at New Orleans. Upon his return home he commenced the study of the law, and having entered upon the practice of it soon gained a local reputation, especially as an advocate before a jury, hardly inferior to that enjoyed by Patrick Henry in the tide-water portion of the commonwealth. He entered public life as delegate from Brooke co. to the lower house of the Virginia legislature in 1815, and continued for several years at various times to represent that constituency. But it was not until the constitutional convention of 1829–'30 had commenced its sessions, that the full intellectual stature of the man was displayed. He was one of the members chosen for the district composed of the counties of Ohio, Tyler, Brooke, Monongalia, and Preston, and one of his colleagues was Alexander Campbell, the founder of the religious sect known as the "Disciples of Christ." Mr. Doddridge was the acknowledged leader in the convention of the party in favor of the white basis of representation, and maintained his ground in the great debate in which Randolph, Leigh, Upshur, Stanard, and Tazewell supported the other side. In this discussion and the innumerable debates which sprung out of it, Mr. Doddridge was, according to Mr. Grigsby, the historian of the convention, "a gushing fountain of facts and figures." He had few of the graces of the accomplished orator; his voice was not musical, and he had little skill in

its management; in person he was of a short and stout stature; his features were immobile, even heavy; and he was singularly negligent of the proprieties of dress; so that his success in parliamentary conflicts was due to a close ratiocination, a perfect knowledge of the subject, great energy of manner, and a wonderful command of terse, appropriate words. He was elected to congress soon after the adjournment of the convention, from the Wheeling district, but his career was brought to a close before his first congressional term had expired. At the time of his death he was engaged in codifying the laws for the District of Columbia as one of a committee appointed by congress for that purpose.

DODDRIDGE, Philip, an English divine, born in London, June 26, 1702, died in Lisbon, Oct. 26, 1751. He was of a pious dissenting family, and his earliest years were devoted to the acquisition of religious knowledge. Even before he could read, his mother had made him familiar with the history contained in the Old and New Testaments. Left an orphan at the age of 13 years, he was removed from London to a private school at St. Albans, where he made the acquaintance of a Dr. Samuel Clarke, who became interested in him for the love of learning which he displayed. Doddridge was at this time hesitating as to what profession he should follow. The duchess of Bedford offered to defray the expenses of his education at either university, a proposal which inspired him with gratitude, but which he declined, on account of the implied condition that he should become a clergyman in the church of England. Some of his friends dissuaded him from the ministry, and he purposed for some time the study of the law. At length, however, he determined to follow his own early inclinations, and in 1719, by the advice and assistance of Dr. Clarke, he entered a dissenting academy at Kibworth, under the charge of the Rev. Dr. Jennings, to prosecute his theological studies. From 1723 to 1729 he fulfilled pastoral duties at Kibworth and the neighboring town of Market Harborough, and in that retired district pursued his studies, reading frequently his favorite authors, Baxter, Howe, and Tillotson. In 1729, Mr. Jennings having previously died, Mr. Doddridge took charge of the dissenting academy where he had been himself educated, established it first at Market Harborough, where he then resided, and within a year removed it with him to Northampton, whither he had been invited as pastor. It was at this academy that the most distinguished dissenting ministers near the middle of the last century were educated. Dr. Doddridge presided over it for 20 years, and during the same time acquired a high reputation as a preacher and an author. It was his aim to revive the ancient fervor of the dissenting body, which seemed to him to be declining; hence all his pastoral intercourse was marked by spiritual earnestness, his sermons urged with zeal the practical duties of life and explained the realities of faith with simplicity, and his books have continued since his death among the most valued devotional literature of the religious community to which he belonged. In 1750 his constitution, always feeble, began to show signs of decline, and yielding to the advice of physicians that he should pass the winter in a warmer climate, he sailed to Lisbon, where he died 13 days after his arrival. His most popular and useful works are the "Rise and Progress of Religion in the Soul," which has been translated into several foreign languages, and his "Family Expositor," containing a version and paraphrase of the New Testament, with notes. He also published several volumes of sermons, the "Principles of the Christian Religion," a "Treatise on Regeneration," and several minor works. His "Course of Lectures on the Principal Subjects in Pneumatology, Ethics, and Divinity" was published posthumously (London, 1763), and gives the outlines of a system of metaphysics and divinity. His works were collected in 10 vols. (Leeds, 1802), and his "Private Life and Correspondence," by one of his descendants, appeared in 5 vols. (London, 1831). Accounts of his life were also published by his contemporary Job Orton, and his pupil Dr. Kippis.

DODGE, a S. E. co. of Wisconsin, intersected by Rock river and one or two smaller streams; area, 936 sq. m.; pop. in 1855, 34,540. There are prairies in various parts of the county, interspersed with oak-openings, and covered here and there with small clusters of burr and pin oaks. The valleys of the streams are occupied by extensive forests of oak, ash, elm, maple, &c.; the soil is calcareous and highly fertile. About 44 sq. m. of the surface are covered by an immense swamp or shallow pond, called Winnebago marsh. The staples are grain, potatoes, butter, and swine; and the productions in 1850 amounted to 327,936 bushels of wheat, 127,672 of Indian corn, 204,197 of oats, 158,228 of potatoes, and 331,246 lbs. of butter. There were 10 churches, and 3,243 pupils attending public schools. Value of real estate in 1855, $3,842,700. Limestone suitable for building is found in large quantities. The Fond du Lac and Chicago railroad passes through the county, and Rock river is navigable by small boats. Capital, Juneau.

DODINGTON, George Bubb, Baron Melcombe, an English politician, born in Carlisle in 1691, died July 28, 1762. He was educated at Oxford, and in 1715 was chosen a member of parliament for Winchelsea. His talents soon attracted attention, and he was appointed to accompany Sir Paul Methuen to Madrid, and not long afterward was made envoy extraordinary to Spain. In politics he was a whig, and joined himself to Walpole, but on the minister refusing him a peerage, which was the chief object of Dodington's life, and to which his vast wealth was his principal title, he went into opposition, and became a patriot. Patriotism not proving profitable, his relations with Walpole were resumed, and he received several valuable appointments.

He remembered the old refusal, however, better than the new appointments, and was conspicuous in those assaults on Walpole's ministry that finally worked its fall. He was not immediately rewarded, but at last got the post of treasurer of the navy. Again changing his views, he joined the prince of Wales's faction in 1749, and by Frederic he was permitted to kiss hands on the promise of a peerage and a cabinet office, to be conferred when the prince should become king. A reward hardly less shadowy was his appointment to the place of treasurer of the chambers in the prince's household, which was specially created for him. The prince and Dodington settled the former's first ministry; but in the middle of their scheming the prince died suddenly, much to Dodington's chagrin, his disappointment taking a pious form of expression. "Father of mercy," he wrote in his famous "Diary," "thy hand that wounds alone can save!" In 1755 he was once more appointed treasurer of the navy, but soon lost the office. In 1761, when he was 70 years old, he obtained the object of his life, being made Baron Melcombe of Melcombe Regis, shortly after the accession of George III., and through the favor of Lord Bute. This success, which gave him the most childish pleasure, he did not live long to enjoy, and on his death the title became extinct. His estates fell to Richard Grenville, Earl Temple, and his personal property was bequeathed to Thomas Wyndham. Mr. Wyndham died in 1777, and his relative, Henry P. Wyndham, published Dodington's "Diary" in 1784. This diary was kept from March 8, 1749, to Feb. 6, 1761, but there are some breaks in it. It affords a lively picture of the parties, politics, and public men of the last years of George II.'s reign, and the portrait he draws of his own selfishness and egotism is almost as frank as if it had been written in the palace of truth. His mind is, as it were, mirrored in its pages, and from the state in which it was left he evidently meant it for publication. There are attached to it several of the author's political papers. The volume, to which Mr. Wyndham attached the appropriate motto of *Et tout pour la trippe*, from Rabelais, has been frequently reprinted, and has some value as historical material. Dodington was a man of much wit, and some of his *mots* are still repeated. He was, however, a butt for ridicule in his own day, and is remembered chiefly as the type of the corrupt and inconstant politician.

DODO (*didus ineptus*, Linn.), a large bird of the island of Mauritius, at present placed in a subfamily of the order *columbæ*, or pigeons. It has become extinct within 2 centuries. This remarkable bird was discovered by Vasco da Gama in 1497, and was mentioned by various voyagers from the Dutchmen Jacob van Neck and Wybrand van Warwijk in 1598, to Captain Talbot in 1697. In the work of Messrs. Strickland and Melville on "The Dodo and its Kindred" (4to., London, 1848) are given many quaint descriptions and figures of the bird, which it appears was not uncommon in the 17th century, and was frequently used as food by the crews of vessels. In 1638 François Cauche says that he saw in Mauritius birds "larger than a swan, covered with a black down, with curled feathers on the rump, and similar ones in place of wings; that the beak was large and curved, the legs scaly, the nest made of herbs heaped together; that they lay but one egg of the size of a half-penny roll or of that of a pelican, and that the young ones have a stone in the gizzard." In the same year a living specimen was exhibited in London, and described by Sir Hamon Lestrange as a "great fowle, somewhat bigger than the largest turkey cock, and so legged and footed, but stouter and thicker and of a more erect shape, colored before like the breast of a young fesan, and the back of dun or deare color." In 1644 the Dutch began to colonize the island, and these birds were soon exterminated by the colonists, and by the dogs, cats, and rats which followed in their train, who devoured the eggs and the young in the nests; after the French took possession in 1715, and named it the Isle of France, the dodo is no longer mentioned as a living bird. This is a most remarkable and clearly proved instance of the extinction of an animal by human agency; and as yet the data for determining the species are less than those left by many animals which perished ages ago from geological causes. Beside the rude drawings of the early voyagers given in the work of Mr. Strickland, there are at least 6 oil paintings by eminent artists which are no doubt faithful copies of the living originals. The first of these paintings, the one copied in all books on natural history, and now in the British museum, is anonymous, but probably by one of the artists who painted the following ones; there are 3 pictures by Roland Savery, one at the Hague, another in Berlin dated 1626, and the 3d in Vienna dated 1628; a 5th painting is in the Ashmolean museum, by John Savery, dated 1651; and a 6th in the gallery of the duke of Northumberland, at Sion House, painted by Goeimare, and dated 1627. The principal remains of the dodo are a foot in the British museum, and a head and foot in the Ashmolean museum at Oxford, England, rendered familiar by numerous casts; the latter are all that is left of the specimen in Tradescant's museum, and all that was saved from the flames which consumed the decayed specimen by the order of the trustees; the head preserves the beak and nostrils, the bare skin of the face, and the partially feathered occiput; the eyes are dried within the sockets, but the horny end of the beak is gone. A cranium exists in the museum at Copenhagen; a collection of bones at Paris, much incrusted with stalagmite, carried there in 1830; and others sent by Mr. Telfair to the Andersonian museum at Glasgow and to the London zoological society in 1833. The latter included a tibia and the head of a humerus of large size, with a broad articulating surface and a sudden reduction of the size of the shaft. The generic charac-

ters are a strong bill, much longer than the head, with the culmen straight at first and then arched to the tip, which is acute and overlaps the lower mandible; the latter has the gonys short and suddenly curved upward; the nostrils are in the membranous portion (which occupies $\frac{2}{3}$ of the bill), oblique and exposed; the wings imperfect; the tail apparently a tuft of 5 feathers, broad and curved upward; the tarsi robust, moderately long, and scaled; the outer toe is shorter than the inner, and the anterior toes are all free at the base; the hind toe is long, on the same plane with the others, and scaled; the claws are short, strong, and blunt. From the imperfect materials at his command, Cuvier ranked the dodo with gallinaceous birds; others have traced out its analogies with the ostrich and with the penguin. Most writers, before the work of Mr. Strickland, considered it a modified form of raptorial bird, and among others De Blainville, Broderip (in the "Penny Cyclopædia"), and Owen. Prof. Owen, in a memoir read before the zoological society in 1846, and published in its "Transactions" (vol. iii. p. 331), from observations on the dissected foot and on the cranium of the Oxford specimen, thinks that the raptorial character prevails, though in an extremely modified form, and that the bird subsisted principally upon decaying organized matter, with such reptiles, fishes, and crustacea as it could seize by means of its well-developed toes and claws. Prof. Reinhardt of Copenhagen first referred the dodo to the pigeon family, and Messrs. Strickland and Melville followed out this idea in the book before alluded to; their conclusions can only be glanced at here. They consider it a frugivorous terrestrial pigeon, colossal and brevipennate, coming near in the bill to the genus *treron* (Vieill.; *vinago*, Cuv.). The chief external characters of resemblance are the soft, depressed, and vascular nature of the long basal portion of the bill; the extent of the bare skin around the eyes and forehead; the hooked and compressed corneous portion of the upper mandible, overhanging the lower; the position of the nostril in the middle of the beak, and near its lower margin; the sudden sinking from the forehead to the beak, and the rapid narrowing in front of the orbits; the short, robust tarsi, and expansion of the lower surface of the toes; the low plane of the hind toe; the relative lengths of the toes as compared with the ground pigeons, the absence of interdigital webs, and the short blunt claws. Among internal characters gathered from the narratives of voyagers and the paintings of the bird from nature, are the presence of a large crop, a very muscular gizzard, the palatableness of the flesh, and the laying of a single egg. Beside these characters are the absence of the vomer; the form and direction of the bones, processes, and foramina of the skull; the form of the metatarsal and tarso-metatarsal bones, processes, and canals; and especially the passage of these canals on the outside of the posterior tarsal ridge. Mr. Allis has detected the presence of only 11 sclerotic plates, as in the pigeons, no other birds having a similar or so small a number, the fewest in the raptores being 14. The few points in which the dodo differs from the typical pigeons, as in the non-development of the wings, the small size of the cranium compared to the beak, and the form of the nostrils, do not afford any ground for approximating it to the raptores. Its food was probably dates, cocoanuts, mangoes, and such other fruits as would fall from the tropical trees; their husks it would tear off with its beak, and even the hardest kernels it could digest with its muscular stomach. It must have been a clumsy bird, ungraceful in its form and motions, to use Mr. Strickland's words, like "a young duck or gosling enlarged to the dimensions of a swan; . . . a permanent nestling, clothed with down instead of feathers, and with the wings and tail so short and feeble as to be utterly unsubservient to flight." At the same time that Mr. Strickland was preparing his work in England, Dr. S. Cabot, jr., of Boston, published a paper in the "Journal of the Boston Society of Natural History" (vol. v. p. 490), entitled "The Dodo a Rasorial and not a Rapacious Bird;" in this he comes to the same conclusions as the first mentioned author, and without any knowledge of his views; he places the dodo among the pigeons, near *vinago*, and lays special stress on the high forehead, the bulging out of the lower mandible on its sides beyond the upper, the general shape and proportions of the foot, the arrangement of the scales, the shape of the claws, and the absence of callosities on the soles; beside, the bird was very fat, its flesh edible, and its stomach very muscular, which is not the case with any rapacious birds. He says "that the dodo was a gigantic pigeon, and that, as its general shape, feathering, &c., resemble more strongly the young than the adult pigeon, we may perhaps be allowed to surmise that it properly belongs to an earlier epoch than the present, and has become extinct because its time was run." Prof. Brandt of St. Petersburg, in 1848, maintained the affinity of the dodo to the *charadriadæ* or plovers, which he styles pigeon-formed or dove-like waders. The testimony, as at present collected, seems overwhelming in favor of the columbine affinities of the dodo.—In the island of Rodriguez lived another large brevipennate bird, the *solitaire*, allied to the pigeons.

DODONA, a city of Epirus, in the N. of Greece, celebrated as the seat of the most ancient oracle of Greece. It was one of the three greatest oracles, ranking with those of Delphi and Ammonium. Though so famous in its day, no vestige of either the city itself or its temple of Jupiter can now be discovered. It is the only place of great celebrity in Greece of which the situation is not exactly known. Before the erection of this temple the oracles are said to have been delivered from a large oak tree, from the whispering branches of which the mysterious sayings of the deity were uttered; and the

old poets have ascribed to the oak grove at Dodona the power of speech. The temple was destroyed by the Ætolians under Dorimachus, 219 B. C., but it was afterward rebuilt, and is mentioned by Pausanias as standing in the 2d century of our era. According to the account given by Lucretius, the fountain in the neighborhood of the temple at Dodona was inflammable.

DODSLEY, Robert, an English publisher and miscellaneous author, born in Mansfield, Nottinghamshire, in 1703, died in Durham, Sept. 25, 1764. He was originally a servant, but having produced in 1732 a volume of poetical pieces, under the title of the "Muse in Livery," and subsequently a dramatic piece called the "Toy Shop," which met with the approbation of Pope, and was acted with great success at Covent Garden theatre in 1735, he was soon in a position to abandon his humble vocation and embark in business as a bookseller. Patronized by Pope, his shop became in time one of the leading establishments in the British metropolis. In 1737 he brought out a farce styled "The King and the Miller of Mansfield," which was received with applause at Drury Lane; and a few years subsequently a ballad farce entitled the "Blind Beggar of Bethnal Green." In 1746 he projected "The Museum, or the Literary and Historical Register," which numbered among its contributors some of the most eminent literati of the day. In 1748 he started another periodical called the "Preceptor," the preface of which was written by Dr. Johnson, and in 1749 he paid the latter 15 guineas for his "Vanity of Human Wishes." In 1750 he published a work styled the "Economy of Human Life," which, though ascribed by some to Lord Chesterfield, was from the first generally supposed, and is now universally admitted, to have been his own production. In 1758 his tragedy of "Cleone" was represented at Covent Garden theatre, on which occasion Dr. Johnson declared that "if Otway had written it, none of his other pieces would have been remembered." In the same year, in connection with Edmund Burke, he projected and started the "Annual Register," which is still published. He was the first to collect and republish the "Old English Plays," by his selection of which (1st ed. edited by T. Coxeter, 1744; 2d ed. by Isaac Reed, 12 vols. 8vo., 1780) his name is now most frequently recalled. He retired from business in 1763 with a handsome fortune. A collected edition of Dodsley's dramas, in one volume, appeared in 1748, and a 2d volume, entitled "Miscellanies," in 1772.

DODWELL, Edward, an English author, born in the latter part of the 18th century, died in Rome, May 14, 1832. In 1819 he published in 2 quarto volumes "A Classical and Topographical Tour through Greece during the years 1801, 1805, and 1806." Dodwell made numerous drawings of ruins and scenery in Greece and Italy, and after his death a collection of some of them was published, entitled "Views and Descriptions of Cyclopean or Pelasgic Remains in Greece and Italy; with Constructions of a later Period, from Drawings by the late Edward Dodwell, Esq., F.S.A., &c., intended as a Supplement to his Classical and Topographical Tour in Greece," &c.

DODWELL, Henry, an Irish writer, born in Dublin about 1642, died in Shottesbrook, Berkshire, June 7, 1711. He was graduated at Trinity college, Dublin, and settled in London in 1674. He was for about 3 years Camden professor of history at Oxford, but lost this office on account of his refusal to take the oath of allegiance to William and Mary. He is known especially as a writer on classical and religious subjects. Among his works may be mentioned *Annales Thucydidei et Xenophontei; Annales Velleiani, Quintiliani, Statiani; De Veteribus Græcorum, Romanorumque Cyclis, obiterque de Cyclo Judæorum ac Ætate Christi, Dissertationes;* and "An Epistolary Discourse, proving from the Scriptures and the first Fathers, that the Soul is a principle naturally mortal, but immortalized actually by the pleasure of God, to punishment or to reward, by its union with the divine baptismal Spirit; wherein it is proved that none have the power of giving this divine immortalizing Spirit since the Apostles, but only the Bishops." This work, as might be supposed, raised a great outcry against the author, who would thus exclude the larger part of mankind from any future existence. See "Life of Dr. Henry Dodwell," by Francis Brokesby (London, 1715).

DOG, a digitigrade carnivorous mammal, belonging to the genus *canis*, and to the family *canidæ*, which also include the wolf, fox, and jackal. The species of this family are so nearly alike in structure that the genera *canis*, *lupus*, *vulpes*, &c., have been established on characters considered of inferior importance in other families; even the intellectual and instinctive faculties have been employed by F. Cuvier and others in distinguishing the species, the domestic dogs being regarded as derived from several distinct though nearly allied wild canines. Except in the size of the bones, there is nothing in the osteology of this family which can be made characteristic of the wild species or of the domestic races when compared with each other, though as a family group they are collectively quite distinct from other digitigrades. In the skulls, the different species of wolf differ more from each other than do many domestic dogs from the wolves; as a general rule, the cranial cavity bears a greater proportion to the face as the intelligence of the animal is more marked. The teeth of dogs, which are largest in the wild species, consist, in the upper jaw, of 6 incisors in the intermaxillary bones; 2 canines, strong, curved, and separated by an interval from the incisors; and 6 molars on each side, the first 3, in interrupted series, being small, but with cutting edges, and called also false molars; the 4th or carnivorous tooth is bicuspid, with a small tubercle anteriorly on the inner side; the 5th is less cutting, bicuspid, with a large internal tubercle; the 6th and last is small and tubercular. In the lower jaw there are 6 incisors; 2 canines, con-

tinuous in the series, and 7 molars on each side, of which 4 are false, the 4th being bicuspid; the 5th or carnivorous tooth has its tubercular 3d lobe entirely posterior; behind this are 2 tubercular teeth, the last being very small and frequently absent in the adult animal. The incisors are regular, the outer being the largest, and nearly perpendicular in the upper jaw; the lower canines shut in front of the upper; the tubercular character of the other teeth indicates a less carnivorous propensity than in the cat family, and that their natural diet is not exclusively animal, being better suited for carrion and broken bones than for the flesh of a living prey. In some species, as the buansu and the dhole, the 2d tubercular tooth is constantly wanting, according to Hamilton Smith. The brain cavity is comparatively small; the crests of the skull and the large temporal fossæ indicate powerful muscles of mastication; the eyes are directed forward; the nostrils are largely opened in a movable glandular muzzle; the tongue is soft, thin at the edges, and capable of considerable extension beyond the teeth, as is seen during rapid breathing in warm weather; the pupil is round, as in other diurnal *canidæ*. The fore feet have 5 toes, the hind feet 4 or 5; the 2 middle toes are the longest and equal; the 5th toe, when present, does not reach the ground; the claws are blunt, strong, not retractile, and formed for digging; the soles are furnished with tubercles, and in some arctic dogs with hair to protect them from cold. The hair is of 2 kinds, soft and woolly near the skin, longer and coarser externally; some of the dogs of India have the skin entirely naked, this condition originating probably from some mangy disease. The tail is generally long, and is curled upward; the number of mammæ varies from 6 to 10; the size, form, and color are different according to the variety. The young are born with the eyes closed, and open them on the 10th or 12th day; the 1st teeth begin to be shed at the 4th month, and the growth ceases at about 2 years of age; gestation is about 9 weeks, and the duration of life is about 10 years, though sometimes prolonged to 20. Though strong, they are not courageous in proportion to their strength; hearing is acute, and the senses of smell and vision are proverbially delicate, the former in the bloodhound, the latter in the greyhound; taste is so dull or perverted that even luxuriously fed pets will not disdain a meal of decaying flesh. Dogs are not so cleanly in their habits as cats; they drink by lapping, require water often, and turn round frequently before lying down; their habits of defecation and micturition are characteristic and well known; their bark is very different from the howl of wild canines, and expresses by its intonation fear, sorrow, anger, joy, and other feelings. Dogs, like all canines, seem to have a natural antipathy to the cat family. All canines, both wild and domesticated, and the nearly allied hyæna, are subject to the terrible disease, hydrophobia. They are spread over all parts of the earth, and all, even the wildest, are capable of some degree of domestication; as the companions of man, dogs are found under all circumstances of human existence.—It would be useless here to introduce anecdotes proving the sagacity, faithfulness, affection, gratitude, courage, velocity, and other useful qualities of the dog; these have been known from remote antiquity, and are recognized in the earliest systems of pagan theology and astronomy. From books, inscriptions, and monuments, we know that in the remotest historic period the domestic dogs were not unlike the present races; and anterior to written history there must have been a long period during which the wild originals were educated to be useful companions. What these wild originals were it is impossible to settle definitely. Some naturalists would make the wolf, others the fox, the stock from which our dogs have come; these opinions can now hardly be seriously entertained; the most that can be asserted with confidence is that no one animal can claim the exclusive paternity of these useful races. We know that there are several species of wild dogs in different parts of the earth, all of which may have been pressed into the service of man; the crossings of these with each other, with the wolf in the north, the jackal in the east, the aguara canines in the south, the fennec in Africa, and the fox everywhere, with the care of man to develop special breeds according to his wants, are sufficient, though they cannot be followed in their details, to account for all and more than the varieties of our domestic dogs. When restored to the wild state, they approximate more or less closely to their original type, whether it be wolf, fox, jackal, or other wild canine. Dogs differ in stature, in the shape of their ears and tails, and in the number of their caudal vertebræ; some have an additional claw on the hind foot, or an extra false molar tooth on one side; the hair differs in color, texture, and length; and all these differences may remain as permanent varieties, like some human races, as long as the circumstances which gave rise to them continue essentially the same. We shall see that there are several undoubted species of wild dogs, to say nothing of wolves, foxes, and jackals, and the capacity for variation within definite limits is certainly great in all domestic animals; and it may be true that, if we begin to make species, we shall not know exactly when to stop; still, the necessary complication of these only shows how vague is the meaning of the word species, and how difficult it is to draw the line between species and varieties, especially when the former are very nearly allied. If the wild original be a wolf, who will indicate what species of wolf is the true and only one? and so of the other assumed types. There is no other instance in the whole range of mammals where man has been able to develop and combine such different and opposite faculties and forms as are seen in domestic dogs, unless the typical species were in possession of the rudiments; neither food, nor

climate, nor human contrivances, could so widen or truncate the muzzle, elevate the frontal bones, diminish the delicacy of smell, and elongate the limbs, unless different types had furnished the properties which man has modified to suit his purposes. In the absence of positive proof, we have every reason to doubt that our domestic dogs can be referred to any single wild original; it is much more reasonable to admit several aboriginal species, with the faculty of intermixing, including, beside wild dogs (like the buansu, dingo, &c.), the wolf, jackal, and fox, as parents of our dogs; that a dhole or a thous may have been the father of the greyhound races; that a lost or undiscovered species, allied to *canis tricolor* or *hyæna venatica*, may have been the source of the short-muzzled, strong-jawed mastiffs. Hamilton Smith classes the dogs according to their apparent affinities with wild canines in corresponding latitudes; the arctic dogs with wolves; the dogs of the south with the jackal in the old world, and with the aguara canines in South America. The Indian dogs may be traced to the prairie wolf and the Mexican coyotl, and in Asia to the jungle koola. Whatever may have been their originals, it is altogether probable that the primitive dogs, like the other domestic animals, were very different from any of the present races, and perhaps from any now existing canines.—The first genus of wild dogs is *lyciscus* (Smith), embracing the prairie wolf and coyotl of North America, and the koola of India; the head is broad, the muzzle pointed, ears erect, fur short, tail bushy; stature about 26 inches; the disposition is more peaceable than that of the wolf; the voice barking; they are gregarious and live in burrows. It is probable that the aboriginal Indian dog is derived from the first two; the color is ashy gray, with some white on the tail and breast; and, when hunting in packs, these animals are hardly to be distinguished from domestic dogs. They are named *L. latrans*, *L. cagottis*, and *L. tigris*. The red wild dogs, forming the genus *chryseus* (Smith), are found in the warmer parts of Asia, Africa, and the Australian islands; the muzzle is less pointed than in *lyciscus*, and the tail less bushy; they are shy and fierce, seldom burrow, hunt in troops, and bark, and are about 24 inches high; they want the 2d tubercular tooth in the lower jaw, and are said to have the soles of the feet hairy; they destroy many of the young of the larger cats; they differ from wolves and jackals in their habits and instincts, and approximate the domestic dog in the small size of the anal glands. The presence of one of these species in Europe probably gave rise by their nightly hunting to the German legend of the wild hunter and his demon hounds. The buansu of Nepaul (*C. primævus*, Hodg.) is of a deep rust color above and yellowish below; it is intermediate in size between a wolf and jackal, hunting by day or night by the scent chiefly, in small troops; there are several varieties in the wooded mountains of British India. The dhole of India (*C. scylax*, Smith) is more slender than the buansu, higher on the legs, with a sharper muzzle, long close-haired tail, and large dark ears; the color is a light bay. The dhole of Ceylon (*C. Ceylonicus*, Shaw) is an allied, if not the same species. The pariah cur dogs of India are not merely degraded mongrels, but are the offspring of an indigenous wild species living in the jungles and in the lower Himalaya range; this resembles the jackal more than the wolf, but is more bulky in body and lower on the legs; the voice is yelping and howling. Other red wild dogs are found in Sumatra and Java. The New Holland dingo (*C. Australasiæ* of authors) is a wild dog which has been partially domesticated by the natives, and is no doubt an indigenous inhabitant, not introduced by man; in its native wilds it howls in a melancholy manner, and it is more than a match for a domestic dog of the same size; it hunts in small packs, sometimes in pairs, and is very active and fierce. It stands about 2 feet high; the color above is fulvous, spotted with white, paler on the sides and throat, and whitish below; it carries the tail horizontally, and runs with the head high and the ears turned forward. The genus *thous*, of which the typical species is the wild dog of Egypt (*C. anthus*, F. Cuv.), resembles the wolf on a small scale, being not more than 18 inches high, of a light structure, with rather short tail, close, ochry fur, barred or pencilled with black and white; the species do not burrow, and are not gregarious, seldom howl, and have no offensive smell; they all have the tip of the tail black, and prefer rocky, sandy districts, where there are bushes and water. Hamilton Smith is of the opinion that the greyhound of the desert was originally derived from one of the species of this section. It is found from Egypt and Arabia to the cape of Good Hope. South America, when first discovered by the Spaniards, had its indigenous canines, all with a tendency to elliptical pupils, though less so than in true foxes; among these are the aguara dogs, genus *dusicyon* (Smith). These are between the wolf and fox in form, with bulky body and short legs; they burrow and are more social and gentle than the aguara wolf (*C. jubatus*, Desm.). This group seems to represent the *thous* of the old world, though the forehead is more rounded, and the tail consists of an imperfect brush; the prevailing color is fulvous brown, often with a hoary tinge; the face looks like that of the fox; they are not very shy, and are capable of being domesticated; they are great thieves, with a propensity to conceal objects of no use as food; beside the usual articles of diet, they will eat fish, crabs, reptiles, insects, small birds, and even mollusks and berries; they are generally silent animals, and hunt by day or by moonlight; they are good swimmers. There are several species described, ranging from Surinam to the Falkland islands; the domesticated specimens differ but little from the wild originals, except in the tail being less bushy; the average height is from 14 to 16 inches; there are 5 toes to each foot,

and the gape of the mouth is large and wolf-like; they hunt pacas, agoutis, and wild gallinaceous birds. All these wild dogs cross with the domesticated ones of the country, forming the most complicated intermixtures.—Before proceeding to the proper domesticated dogs, it will be well to notice certain varieties which have relapsed into a wild state, and, subsisting for several generations by their own resources, have resumed most if not all of the original characteristics of that state. In Asia Minor there is a race of these feral dogs (as Hamilton Smith calls them), of nearly the size of the local wolf, and resembling the shepherd's dog except that they have a more bushy tail, sharper nose, and the fur rufous gray, and that they hunt in packs in open day. A smaller breed is found in Russia. In St. Domingo there is a large feral dog of the race of hounds formerly used by the Spaniards in their western conquests; this dog is of large size, about 28 inches high, with a head like a terrier, and the general color pale bluish ash; its scent is very fine, and it follows its prey with great speed, attacking it with ferocity when overtaken; flocks sometimes suffer from its depredations; it is believed that it was introduced into Spain from the north, such is its resemblance to the Danish dog. In the pampas of South America are troops of feral dogs, a mixture of all the breeds of the country; their ears are erect as in true wild canines; they are bold and cunning, destroying many of the young of the wild herds of cattle and horses; when redomesticated, they are remarkable for their courage, sagacity, and acute sense of smell. —Of the true domesticated races, the arctic dogs of both hemispheres are of large size, wolfish aspect, with pointed nose, erect ears, and long hair of mixed black and white colors; they are fierce in their dispositions, bold, and strong; they swim excellently, burrow in the snow, and will drag the native sledges for hours at a time several miles an hour. The recent arctic voyages in search of Sir John Franklin have made the reader familiar with the habits and valuable properties of the Esquimaux dogs, and even their appearance is well known from specimens brought home by the returned explorers. This species (*canis borealis*, Desm.) is probably the same as the Siberian dog. The Hare Indian dog (*C. lagopus*, Rich.), according to Sir John Richardson, is peculiar to the region of the Mackenzie river and Great Bear lake; it is intermediate in size between the wolf and fox, has erect ears, bushy tail, and a general gray color, with white and black markings; the hair is long, and at its base, as in all arctic dogs, is a thick wool; it is about 14 inches high, and is used for hunting and not for draught; it is playful and affectionate, though not very docile. These arctic canines, if not pure wild species, are probably the result of a mixture of the wolf and the lyciscan dogs before described. In the territory of the Hudson's bay company, in Canada, and in the Lake Superior mineral district, there is a mongrel race of dogs which take the place of horses during the winter season, travelling over the snow, attached to the dog train, transporting provisions, merchandise, and even the mails; they are hardy, easily managed, strong, bearing abuse, scanty food, and fatigue without murmur; they are invaluable to the hunter, Indian, half-breed, and traveller in these snow-clad regions; no particular breed is sought for, the only qualities valued being strength and endurance. The Newfoundland dog (*C. Terræ Novæ*, Smith) seems to be indigenous to America; it is longer than the Esquimaux dog, less compact, with a wider muzzle, drooping ears, and with long hair disposed to curl; it is a handsome and powerful dog, very intelligent and trusty, and of a kind disposition; the pure breed is almost semi-palmated, making them the best water dogs; crossed with the hound, they attain an enormous size; the general color is black, with some fulvous about the eyes, nose, throat, and joints, and white about the feet and end of the tail. Anecdotes of the sagacity of this well-known breed are innumerable. The Nootka dog (*C. laniger*, Smith) is noted for its thick and matted fur, which the natives mix with wool and make into garments; the describer of this species thinks that it indicates that the Esquimaux and Newfoundland races were derived from Asiatic originals, perhaps from the dog of Siberia. At the head of the list of the domestic canines of temperate Europe stands the shepherd's dog (*C. domesticus*, Linn.), still with the wolf-like stature, head, and hair; its appearance is rather unpromising; its shaggy hair is generally varied black and gray, the ears are short and erect, and the tail is bushy and curved; having been trained from time immemorial to the care of flocks, its peculiar faculties seem to be instinctive, and its sagacity, fidelity, and courage are not excelled by any species of dog; the height is not quite 2 feet, but the form is muscular. This breed is confined to temperate and southern Europe. The true shepherd's dog attends the flocks, keeps them together, and protects them from violence. A variety called the drover's dog, somewhat larger and more rugged, is of great assistance in driving sheep and cattle to market. The great wolf-dog (*C. Pomeranus?* Linn.) has all the sagacity of the shepherd's dog, with a strength which enables him to resist successfully the attack of a wolf; it is of large size, whitish clouded with brown, with pointed nose, erect ears, and long silky hair; it is most common in southern Europe. The Alpine or dog of St. Bernard is universally known for his services in discovering and assisting snow-bewildered travellers in the higher Alps; the old race resembled the Newfoundland dog, but the present dogs are short-haired, with very broad feet, and generally of a fawn color; their bark is uncommonly loud and deep. They are trained to carry food, wine, and warm coverings, attached to their bodies and necks; they depart in the morning, after violent snow storms, in search of buried travellers, and are followed by

the monks. Many lives have been saved through their instrumentality; but at the present time, when the roads are better and more easily followed, and the inhabitants in the upper valleys more numerous, their services are less frequently called for. In the subdivision of the watch dogs of F. Cuvier are found some of the largest canines, and especially the fierce races mentioned by ancient authors; they have short hair and a wide muzzle, but in their skulls they resemble the wolf; the typical color is rufous, which is more or less mixed with black and white; occupying the northern temperate zone, they are probably descended from the lycisean dogs, mixed toward the south with the mastiff race. They are less docile and sagacious than the former groups, but more watchful and noisy, and with considerable courage, and are therefore generally kept by the humbler classes to protect their farms; from this cause they are greatly crossed, and are doubtless the progenitors of the mongrel races of western Europe; from their moderate powers of smelling they are of little use in hunting. The Suliote dog (*C. Suillus*, Gmel.), sometimes called boar hound in Germany, is one of the largest and fiercest breeds; it has been known to be nearly 4 feet high at the shoulder. Resembling this is the Danish dog (*C. glaucus*, Smith.), but smoother, with shorter ears, and of a slaty blue color. The matin dog (*C. laniarius*, Linn.) has the head elongated and the forehead flat, the ears pendulous at the tips, the hair rugged, of a yellowish fawn color with blackish rays; the height is about 2 feet; being bold, strong, and active, it is valuable for a house and sheep dog. The Poe dog (*C. Pacificus*, Smith) seems to be indigenous to the South sea islands, and once was very abundant in the Sandwich group; the muzzle is pointed, the ears erect, the back long, the limbs crooked, and the hair smooth and tan-colored; its food is vegetable, with a little fish, and it is much esteemed by the natives as an article of diet; the aboriginal race is now lost, from mixture with the imported dogs of Europe. The dogs of Patagonia are as large as fox hounds, and wolf-like in appearance; those of Terra del Fuego are smaller, resembling a cross between the fox, shepherd's dog, and terrier; their dogs are of great value to the natives of these regions. In France and several other countries, especially Holland, dogs are frequently employed as draught animals, and in Kamtchatka and Greenland, almost exclusively for the same purpose.—From the above remarks it must be evident that the dogs are the most complete and useful conquest ever made by man; all their faculties have been rendered subservient to him, for his pleasure and profit, for his safety against his own kind and other animals. Cuvier has asserted that the dog was perhaps necessary for the establishment of human society; though this may not be apparent in the most highly civilized communities, a moment's reflection will convince us that barbarous nations owe much of their elevation above the brute to the possession of the dog. That man has been able to make such extensive use of this animal must depend on innate qualities in the races, as, for instance, keenness of scent and the desire to chase, in the hound; the impulse to seek objects, in the spaniel and pointer; the tendency to watch and guard, in the shepherd's dog and mastiff. The activity of their brain is shown by their proneness to dream, during which state they go through all the mental exercises they would use when awake. It is said that the ancients were fond of the flesh of dogs; it is well known that the Polynesians, Chinese, and American Indians consider it a great delicacy; when fed principally on vegetable food, it is palatable and nutritious, as many a traveller in the Rocky mountains and in the northwest territories has had occasion to experience.—The monuments of Egypt show that dogs, like men, were as distinct in their races thousands of years ago as at the present day; and it becomes interesting to inquire if there are fossil dogs. Fossil canines have certainly been found, but these have without examination been referred as a matter of course to wolves, foxes, and jackals, and not to dogs; these are chiefly met with in the pliocene caves, in the drift, and in the alluvium. It has been already mentioned that it is very difficult to distinguish the different species of *canidæ* by their skeletons, except by the size of the bones. The teeth of the domestic dog have the last tubercular tooth wider than that of the wolf, and the teeth of many of the cave dogs differ from those of the domestic races only in being larger. Dr. Lund discovered fossil dogs larger than any now living in the caves of Brazil, associated with an extinct monkey; a similar association has been found in a stratum of marl, under compact limestone, in the Pyrénées. Dr. Schmerling has described several fossils of the true dog, evidently belonging to 2 distinct varieties, differing in size from those of the wolf and fox found in the same locality. Cuvier says of the bones of a fossil *canis* from the cave of Gaylenreuth, that they resemble those of the dog more than the wolf, yet he does not positively declare them to belong to the former. Marcel de Serres has described 2 species of dogs found in a marine tertiary limestone, one resembling the pointer, the other much smaller. The frontal elevation in the skull of the dog is greater than that of the wolf, and the skull of a small canine with this character strongly marked, from a bone cave in England, was pronounced by Mr. Clift that of a small bull-dog or a large pug. Distinct traces of at least 4 types of dogs have been found in a fossil state, the Canary dog, the pointer, the hound, and the bull-dog, with a smaller one classed by Schmerling with the turnspit; and as many of these are known to be hybrids, the list must probably be further enlarged. The certain antiquity of these bones, whether they have been referred to the proper race of dogs or not, is sufficient to destroy the claims of the wolf, or

jackal, or fox, to the exclusive paternity of the domestic dogs. As there are undoubted wild canines which are true dogs, there is no improbability that some of these fossil remains may have belonged to such prior to their subjugation and domestication by man; and there is no more necessity of referring the fossil canines to a single species than the domesticated ones. The size of the fossil dogs is no greater than that of some living races mentioned in the text.—Those desirous of pursuing the subject of dogs more fully are referred to the writings of Buffon, Frédéric Cuvier, and Col. Hamilton Smith. (See also BEAGLE, BLOODHOUND, BULL-DOG, GREYHOUND, HOUND, MASTIFF, POINTER, SPANIEL, TERRIER.)

DOG DAYS (Lat. *dies caniculares*), among the ancients, the period of greatest heat in summer, so named because in the latitudes of the Mediterranean this period nearly corresponded with that in which the dog star rose at the same time with the sun. To this conjunction all antiquity, and all the later followers of judicial astrology, ascribed a malignant influence. The heliacal rising of the dog star is a very indefinite phenomenon; its precise dates cannot be determined, and owing to the precession of the equinoxes it does not now occur till about Aug. 10, when the greatest heat of the season is often over. So uncertain is the time that the ancients indiscriminately ascribe the evil influence to Sirius and Procyon (the largest stars respectively of Canis Major and Minor), though there is several days' difference in their heliacal risings. The modern almanac makers sometimes reckon the dog days from July 24 to Aug. 24, and sometimes from July 3 to Aug. 11.

DOG-FISH, a cartilaginous plagiostome, of the family *squalidæ* or sharks, and the genus *acanthias* (Risso), of the class selachians of Agassiz. This genus is characterized by 2 dorsal fins with a strong spine before each; the 1st dorsal is behind the line of pectorals, the 2d between the ventral and caudal spaces; no anal fin; temporal orifices large; skin rough in one direction, the scales heart-shaped with a central spine directed backward; teeth in several rows, sharp and cutting, with the points directed backward and outward. The common dog-fish (*A. Americanus*, Storer) has the upper part of the body of a slate color, deepest on the head and lightest on the sides, and white below; just under the anterior portion of the lateral line is a row of circular white spots, and a few similar ones are irregularly distributed on the back; the young are still more spotted; the length does not exceed 5 feet. The species is found from Davis's straits to New Jersey. Dog-fish in spring and autumn appear in large numbers in Massachusetts bay, and the residents of some towns on Cape Cod give up all other business at these times to fish for them; they are valuable for the oil from the livers, for the food of cattle, and for the polishing property of their skin. The weight varies from 8 to 25 lbs.; they remain in shallow water 3 or 4 days, at which time they are easily caught by the hook; they feed on garbage, and may properly be called the scavengers of the sea. The young are brought forth alive, and are often seen swimming about with the yolk bag attached. In the British provinces they are dried, and in the winter given to pigs, which thrive well upon them; the refuse parts are used for manure. The dog-fish (*acanthias*) of Europe is a different species; its flesh is eaten in Scotland. Along the east coast of England it is called the bone-dog; it is a great pest to the fishermen by cutting off their hooks; according to Mr. Couch, it bends itself into a bow for the purpose of using its spines, and then by a sudden motion causes them to spring asunder in opposite directions. Three species of *scyllium* (Cuv.), of a reddish-brown color with numerous spots, are called dog-fish in Europe. There is another shark (*mustelus canis*, Mitch.), also viviparous, called dog-fish. In this genus the teeth are blunt, forming a close pavement in each jaw; the first dorsal is in advance of the ventrals; there are no spines; the body is cylindrical and elongated, of a uniform slate color on the back and sides, and dusky white below; the head is flat between the eyes. This shark grows to a length of 5 feet, and is very common in Long Island sound, where it is taken in nets spread for other fish; from the form of the teeth it is probable that the food consists principally of crustacea and mollusks; it is not common on the coast of Massachusetts, but is abundant on the shores of New Jersey, where it is very troublesome to the fishermen by stealing their baits and driving away other more eatable species; its flesh is coarse, rank, and unpalatable, though occasionally eaten. In Europe the species of this genus are often called hound-fish; the *M. lævis* (Cuv.) is called the smooth hound from the softness of the skin, and ray-mouthed dog-fish from the peculiar conformation of the teeth. These sharks are called dog-fish probably from their hunting for prey or food in large packs, like hounds. The dog-fish of the great lakes of North America is a soft-rayed bony fish, generally placed in the herring family, and the genus *amia* (Linn.); the spotted *lota*, one of the cod family inhabiting fresh water, is also incorrectly called dog-fish by Lesueur.

DOG GRASS. See COUCH GRASS.

DOG STAR, or SIRIUS, the brightest and in appearance the largest of the fixed stars, named from the constellation Canis Major in which it appears. It is the Sothis of the ancient Egyptians, and is one of the 6 fixed stars which Ptolemy enumerates in his catalogue as of a fiery red (*ἱπποκίρρος*) color. Seneca also calls it (*Nat. Quæst.* i. 1) redder than Mars. It has at present a perfectly white light, and furnishes the only example of a historically proved change of color in the appearance of a star. It was undoubtedly already white in the time of Tycho Brahe, but of the period of its change there is little evidence. The Arabic astronomer El Fragani (Alfraganus), of the 10th century, invari-

ably follows Ptolemy, and, if Sirius had then been white, would hardly have failed to notice and remark upon the change. The Egyptians reckoned their year from one heliacal rising of the dog star to another, which was therefore called the "Sothic year."

DOGE (Lat. *dux*, a leader), the title of the elective chief magistrate in the republics of Venice and Genoa. The dignity or office was called *dogato*. The doges of Venice were elected for life. The first of them was called to the dignity in the year 697, when Venice had scarcely risen to the importance of a city, and he and his successors ruled it as sovereigns, with nearly absolute power. But when the state grew mightier, both on land and sea, through commerce and conquests, its proud and wealthy nobles continually strove to check the power and influence of their elective head, and the government became more and more oligarchical, its form more and more republican, the dogate a magistracy, and finally a mere title. A great change in the constitution toward the end of the 12th century put the whole legislative power into the hands of the council of 470; this elected the executive council of 6, and the 60 *pregadi*, and the doge was elected by 12 electors, chosen by 24 members of the great council. The first chief magistrate thus elected was Sebastiano Ziani (1173), who, in order to make his dignity, now stripped of every power, at least popular, distributed money among the people at his installation; an act adopted by his successors as one of the ceremonies of inauguration. Another ceremony, introduced by the same doge, was that of marrying the sea, by a ring thrown into the waves of the Adriatic, which emblem of power over the mighty element was bestowed upon him with many other marks of dignity by Pope Alexander III., whom he supported in his long and bloody struggle against the emperor of Germany, Frederic Barbarossa. A new council of 40, established in 1179, and vested with supreme juridical power, also served to circumscribe the prerogatives of the doge. It was in vain that many a chief magistrate covered his office and the state with glory; in vain that Enrico Dandolo, the nearly blind octogenarian, led the victorious fleet of the 4th crusade to Constantinople (1202–'4), that he was, at both attacks, among the first to storm it, that he refused the conquered imperial crown; the growing and grasping might of the nobility was incessantly bent on the humiliation of the so-called chief of the state, which was completed in the 2d half of the 13th century, and at the beginning of the next, by the new and last election law, the most complicated instrument of indirect exercise of sovereignty that has ever been framed, by the introduction under Gradenigo of the hereditary nobility and its golden book, and the establishment of the terrible council of 10, supreme in power, irresponsible, and judges of the doge himself. Stripped of nearly all his prerogatives, the power of the doge was confined to the command of the army and the opportunity of profiting by the frequent strifes and contentions of the different councils and classes; and the office became so burdensome, that a law had to be framed (1339) prohibiting any one from laying it down, and that, in 1367, Contarini had to be forced to accept it. The doge was now but the president of the council, the mouthpiece of the republic; he received ambassadors, but could give them no answer of his own, and their letters he opened in the presence of the senate; money was struck in his name, but without his stamp or arms. He was not allowed to leave the city, to announce his accession to any but princes of Italy, to accept presents, to possess estates in foreign countries, or to marry his daughters to foreigners. His children and relatives were excluded from every important office. He was surrounded by spies, fined for every transgression, and his conduct scrutinized after his death by a tribunal of 3 inquisitors and 5 correctors. The chief magistrate was powerless, while the republic was mighty from its conquests in Greece, rich from the commerce of the East, and glorious in the sciences and art; he remained powerless when the republic, stripped of its eastern possessions by the Turks, of its commerce and wealth by the new maritime discoveries, languished and decayed. The office was destroyed with the state in 1797, by the French, under Bonaparte.—In Genoa, the first doge was elected for life in 1339, after the victory of the popular party over that of the nobility, and voluntarily shared his power with a council of state consisting of 12 members, 6 from the nobility, and 6 from the people. But during the long internal and external contentions of this republic, almost continually agitated by schemes of conquest and party struggles, the dogate was often modified, and sometimes even abolished. Andrea Doria, the great admiral, and the deliverer of the republic from the yoke of the French in 1528, reorganized it, and his constitution remained, but slightly altered, till the time of the French conquest (1797). According to it, the doge, who must be a noble, and 50 years of age, was elected for 2 years; he presided in the 2 legislative councils, of 300 and of 100; had the right of proposing and vetoing laws; exercised the executive power with 12 secret councillors; and resided in the palace of the republic. The ceremonies and restrictions connected with his election and dignity were similar to those in Venice. Napoleon, having founded the republic of Liguria, restored this ancient dignity (1802), and abolished both when elected emperor of the French (1804).

DOGGER, the name of a small vessel used by the Dutch fishermen, especially in fishing on the Doggerbank. It has 2 masts, and is not unlike a ketch.

DOGGERBANK, an extensive shoal in the centre of the North sea. The water on this bank where it is most shallow is 9 fathoms in depth, and abounds in fish. An obstinate naval battle was fought there on Aug. 5, 1781, between the

Dutch and English fleets, in which both were much crippled, and neither could claim the victory.

DOGS, Isle of, or Poplar Marshes, a peninsula in the river Thames, 3 m. below London, and opposite Greenwich. It is bounded on the north by the West India docks, and is rapidly filling up with establishments for heavy manufacturing, iron ship building, gas works, &c. The name is derived from its having been formerly the place where the king's hounds were kept.

DOGWOOD (*cornus*, Linn.), a shrub or tree of the order *tetrandria monogynia*, under the middle size, deciduous, a native of Europe, Asia, and North America, of which there are several varieties. *C. alternifolia* (Linn.), the alternate-leaved dogwood, is a small deciduous tree indigenous to North America, and is found in shady woods or by river banks in every latitude. It frequently attains a height of 15 to 20 feet. The leaves are alternate, ovate, and acute; flowers white, May to July; fruit purple, ripening in October. Of all the species of the genus the florida dogwood (*C. florida*, Linn.) is the most beautiful, and in its native soil under favorable circumstances attains a height of 30 to 35 feet. The specific name *florida*, from *floreo*, to blossom, was bestowed because of the profusion of the flowers it puts forth. Specific characters: branches shining; leaves ovate, acuminate, pale beneath; flowers umbellate, protruded after the leaves; leaves of involucre large, roundish, retuse; pomes ovate; flowers white and very large. It is found as far north as New Hampshire, but particularly abounds in New Jersey, Pennsylvania, Maryland, and Virginia, where the soil is moist; in Florida and the Carolinas it deserts the barrens and is found only in swamps. In Ohio, Kentucky, and Tennessee, it is not found in the forests except where the soil is gravelly. It was first described in Ray's *Historia Plantarum*, published in 1680, and afterward by Catesby in his "Natural History of Carolina." William Bartram, in his "Travels in Carolina and Florida," published in 1791, describes a remarkable grove of dogwood trees in Alabama, extending for 9 or 10 miles. The trees were about 12 feet high, spreading horizontally, their limbs meeting and interlocking with each other so as to form one vast, shady, cool grove, so dense and humid as to exclude the sunbeams and prevent the intrusion of almost every other vegetable. The wood of this tree is hard, fine-grained, and susceptible of a high polish. It enters into the construction of many articles of ornament and utility, such as the handles of mallets, toys, harrow teeth, hames for horse collars, and the shoeing of sleds. The inner bark of the tree is very bitter, and has proved an excellent substitute for Peruvian bark in intermittent fever. Dr. Walker of Virginia, in a dissertation on the comparative virtues of the bark of these 2 plants, says that a summary recapitulation of the experiments made by him shows that the *cornus florida* and the Peruvian bark possess the same constituents, that is, gum, mucilage, and extracts, which last contain the tannic and gallic acid, though in different proportions. Their medicinal virtues appear similar and equal in both forms. The extract and resin possess all their active powers. The bark may likewise be substituted for galls in the manufacture of ink. From the bark of the roots the Indians extract an excellent scarlet dye. The florida dogwood is often cultivated as an ornamental tree, its large flowers, which rival the whiteness of snow, affording a pleasing contrast with the deep green of the surrounding foliage.—The name dogwood is improperly given in some parts of the United States to the *rhus venenata*, a species of poisonous sumach.

DOHNA, a German family of counts (*Burggraf*), who trace their origin to the times of Charlemagne, and many of whom have occupied high positions in the military and civil service of Prussia.—Karl Friedrich Emil, born March 4, 1784, president of the military department in the Prussian cabinet and general of cavalry in 1854, when he retired from active service, died in Berlin, Feb. 21, 1859.

DOKOS, or Dokoes, a race of negroes said to inhabit a region of tropical Africa, S. of Abyssinia, near the river Gojeb. They were first fully described by the missionary Dr. Krapf, on the credit of a Galla slave who had visited their country, and whose relation was thought to bear every mark of truth, and was corroborated by other native accounts. According to this man, the Dokos are 4 feet high, of a dark olive complexion, and perfectly wild. They go naked, feed on ants, snakes, mice, and fruits, evince considerable intelligence, and are in great request by the people of Kaffa as slaves. They have no government, no laws, no priority of rank, no national feelings, no idea of marriage, and very little sense of religion. The mother abandons her child as soon as it is able to procure its own food. Their country is subject to almost incessant rains, and on account of the hostility of the surrounding nations is difficult of access. It is rarely visited except by slave dealers, who surround the wretched savages in their thick forests, entice them down from the trees in which they take refuge, and drive them into the plains, where immense numbers of them are captured. They have a horror of slavery, but easily become attached to their masters. They are supposed to be the "pigmies" whose existence has been a favorite belief since the days of Homer.

DOL, a French town, capital of a canton of the same name, in the department of Ille-et-Vilaine; pop. 4,181. It is wretchedly built, but contains a fine cathedral, and possesses considerable historical interest. During the middle ages it was again and again besieged, and passed into many different hands. In 1793 it was garrisoned by the Vendeans, and successfully resisted an attack of the republican troops. The old fortifications of the town are still standing. Its trade is principally in corn, hemp, and cider.

DOLABELLA, Publius Cornelius, a Roman

general, celebrated for his profligacy, born about 70 B. C., died 43 B. C. Notwithstanding his debauched character, he became the son-in-law of Cicero, and enjoyed several high offices of state. After the death of Cæsar, Dolabella, although the former had always been his friend, professed the utmost contempt for his memory, and, being supposed a good republican, obtained the consulship, and afterward from Antony the administration of the province of Syria. On his way thither, however, he committed such atrocious extortions and crimes that the senate declared him an enemy of the republic, and he was killed by one of his soldiers at his own order, to avoid falling into the hands of his enemies.

DOLCI, or Dolce, Carlo, or Carlino, an Italian painter, born in Florence, May 25, 1616, died there, Jan. 17, 1686. His father, grandfather, and uncle were all painters, and after the death of his father, his mother placed him at the age of 9 with Jacopo Vignali. Under Vignali's tuition Carlo's genius developed itself with such remarkable rapidity that after a few years he was able to attempt successfully a full-length figure of St. John. He next produced a picture of his mother, and the delicacy and tenderness which marked these early productions attracted much attention, and procured for him employment at home and abroad. Pietro de' Medici was among his earliest patrons, and brought him into notice at court. He devoted himself almost exclusively to sacred subjects, a branch of the art in harmony with his devout disposition. His works are deficient in imaginative genius, but they are all distinguished by agreeable coloring, a remarkable relief produced by his skilful management of chiaroscuro, a singular delicacy of composition, and a finish in which he approached almost the consummate patience and industry of the great Dutch masters. Although he was proverbially slow in the execution of his paintings, he amassed sufficient wealth for the honorable support of his family of 8 children. The sameness of expression in most of his pictures facilitates copies and imitations, which consequently abound all over Europe. He excelled most in small pictures, and the themes in which he was most successful are borrowed from the New Testament. Among his best works are the "St. Anthony" in the Florentine gallery, the "St. Sebastian" in the palazzo Corsini, the "Four Evangelists" in the palazzo Ricardi at Florence, and "Christ Breaking the Bread," in England, in the marquis of Exeter's collection at Burleigh. Dresden possesses several of his works, including "Herodias with the Head of John the Baptist" and "St. Cecilia, or the Organ Player." Another of his chief productions, "Christ on the Mount of Olives," is at the Louvre in Paris. —Agnese, one of his daughters, who married a merchant named Carlo Baci, was one of his best pupils, and the most successful copyist of his works.

DOLE, a town of France, capital of an arrondissement of the same name, in the department of the Jura; pop. of the town in 1856, 9,443, and of the arrondissement 72,185. It is neat and well built, and situated on the slope and at the foot of a hill on the right bank of the river Doubs, near the canal that joins the Rhone and the Rhine. The railway from Dijon to Besançon, which passes the town, gives it some importance as a place of transit between Paris and Switzerland. It is of great antiquity, having been founded by the Romans, and is situated on the old road leading from Lyons to the Rhine. Some remains of this work, as well as of an ancient aqueduct and theatre, are still to be seen. It was for a time the capital of Franche Comté, and the seat of a parliament. After having been taken once or twice previously, it was captured and dismantled by the French in 1674.

DOLET, Étienne, a French scholar and printer, born in Orleans in 1509, burned as a heretic in Paris, Aug. 3, 1546. He was very fond of classical studies, and was one of the especial admirers of Cicero, who were ridiculed by Erasmus, and warmly defended by Dolet and others. He was of a rash, impetuous disposition, which made him many enemies, who lost no opportunity of persecuting him. Having been often accused of cherishing heretical sentiments, he was at last adjudged an atheist by an ecclesiastical court at Paris, in consequence of an expression which he made use of in his translation of the *Axiochus* of Plato, which was not to be found in the original; and for this he was condemned and burned.

DOLGORUKI, the name of a princely Russian family, whose origin is carried back to Rurik, and several members of which occupy a place in the history of their country. I. Grigori, distinguished himself by the valiant defence of a monastery near Moscow against the Poles under Sapieha and other generals (1608–'10). II. Maria, was married in 1624 to Czar Michael, the first of the house of Romanoff, but died 4 months after. III. Yuri, a general in the reigns of Alexis and Fedor, was killed in the revolt of the Strelitzes after the death of the latter czar in 1682, while defending the right of the young Peter the Great to the throne. IV. Mihail, son of the preceding, and minister of Fedor, perished with his father. V. Yakob, a senator of Peter the Great, noted for his boldness and frankness toward his master, died in 1720. It is said that one day, having torn to pieces an imperial ukase in full council of the senate, he appeased the wrath of the czar, who threatened to kill him, by the words: "You have but to imitate Alexander, and you will find a Clitus in me." VI. Ivan, was the friend of Peter II., to whom his sister Catharine was betrothed; but the young czar having died on the day fixed for the marriage (1730), he was exiled to Siberia with all his family by Biron, duke of Courland, the favorite of the empress Anna. Recalled from exile, he was accused of a conspiracy against the life of the empress, and executed at Novgorod in 1739, other members of the family being beheaded or exiled. VII. Vasili, commanded the army of Catharine I.

in the war against Persia, was made field marshal in 1728, banished to Siberia in 1739 as an accomplice of the preceding, recalled by the empress Elizabeth, and died in 1755. VIII. VASILI, nephew of the preceding, commander-in-chief of the army of Catharine II., conquered the Crimea in a short campaign in 1771, and received from the empress the surname of Krimskoi. IX. VLADIMIR, resided for 25 years as minister of Catharine II. at the court of Frederic the Great, whose friendship he gained. X. YURI, commanded in the wars of Catharine II. against the Turks and Poles, signalizing himself by his valor. XI. IVAN, one of the classical poets of Russia, was born in 1754, and died in St. Petersburg in 1823. XII. PAVEL, was the author of a *Notice sur les principales familles de Russie* (Brussels, 1843), an English translation of which, with annotations and an introduction, appeared in London in 1858.

DOLLAR, the monetary unit in the United States and several other countries, both of coined money and money of account. All values in the United States are expressed in dollars and cents, or hundredths. The term mill, for the $\frac{1}{1000}$ of a dollar, is rarely employed. The dollar unit, as a money of account, was established by act of congress of April 2, 1792, and the same act provides for the coinage of a silver dollar "of the value of a Spanish milled dollar as the same is now current." The silver dollar was first coined in 1794, weighing 416 grains, of which 371¼ grains were pure silver, the fineness being 892.4 thousandths. The act of Jan. 18, 1837, reduces the standard weight to 412½ grains, but increases the fineness to $\frac{900}{1000}$, the quantity of pure silver remaining 371¼ grains as before; and at these rates it is still coined, in limited amount. The smaller silver coins are not of equal weight proportionally. (See COINS.) The act of March 3, 1849, directs the coinage of gold dollars. They were issued the same year, weighing $25\frac{8}{10}$ grains, $\frac{9}{10}$ fine, $23\frac{22}{100}$ grains being pure gold. All other coins of the United States are either multiples or subdivisions of the dollar. The term dollar is of German origin. During the years 1517–'26 the counts of Schlick, under a right of mintage conferred by the emperor Sigismund in 1437 upon their grandfather, Casper Schlick, caused to be struck a series of silver coins of 1 ounce weight, and worth about 113 cents of our money. These pieces were coined at Joachimsthal (Joachim's valley), a mining town of Bohemia, and came to be known in circulation as *Joachimsthaler*, and then for shortness *Thaler*; and this name for coins and money of account has been widely used in the German states ever since. Some German scholars, however, derive the term *Thaler* from *talent*, which was used in the middle ages, designating a pound of gold. In Norway and Sweden we find the *daler*, and in Spain the *dalera*, the famous Spanish dollar which for centuries figured so conspicuously in the commerce of the world. It was the Spanish pillar dollar (called also the milled dollar for its milled edge) that was taken as the basis of the United States coinage and money of account. By the act of April 2, 1792, 371¼ grains of pure silver and 24¾ grains of pure gold were declared to be equivalent one to the other, and to the dollar of account. At that time, as now in Great Britain, 113 grains of pure gold were the equivalent of the pound sterling. The value of £1 in federal money, therefore, was $4 56.5. Prior to this date, and during the confederation, the dollar of account, as compared with sterling currency, had been rated at 4*s.* 6*d.*, which was an exaggerated valuation of the Spanish dollar; and in precise accordance with this valuation the congress of the confederation had established $4 44.4 as the custom house value of the pound sterling. The effect of the act of 1792 was really to reduce the value of our dollar of account, but apparently to increase the value of the pound sterling about 2¾ per cent. By the act of June 28, 1834, the weight of fine gold to the dollar was reduced from 24.75 to 23.20 grains; and 3 years later, Jan. 18, 1837, it was fixed at 23.22 grains, where it now remains. Comparing this latter weight with the pound sterling of 113 grains, we find an apparent increase in the value of £1 to $4 86.6, an advance of exactly 9½ per cent. upon the old valuation of $4 44.4. We have here the explanation of the existing practice in this country of quoting sterling exchange at 9½ per cent. premium, when it is really at par. A much more simple and intelligible method would be to state in dollars and cents the ruling rate per pound sterling for bills on London, *e. g.* $4 84, $4 87, $4 90, &c. Spanish dollars were chiefly coined in the Spanish American colonies. The best known variety was the pillar dollar, so called from the 2 pillars on its reverse, representing the "Pillars of Hercules," the ancient name of the opposite promontories at the straits of Gibraltar. The rude imitation of these pillars in writing, connecting them by a scroll, is said to have been the origin of the dollar mark ($), now universally familiar. A more plausible explanation is that, as the dollar consisted of 8 *reals*, 8 R. being stamped upon it, the mark was designed to stand for the "piece of eight," as the dollar was commonly called. The two vertical lines distinguished it from the figure 8. The Spanish American dollars ceased to be coined when the colonies became independent, and since 1822 their place in commerce has been supplied by the dollars of Mexico, Bolivia, and Peru. (For values, &c., see COINS.)

DOLLART BAY, or THE DOLLART (Lat. *Sinus Emdanus* or *Dollarius*), an arm of the German ocean, about 10 m. in length from N. to S., and 7 m. in breadth. It lies between Hanover and the Netherlands, and extends to the estuary or mouth of the river Ems. It is supposed to have been formed by a terrible inundation in 1277, which destroyed nearly 50 villages. The sea has since receded in some measure from the Hanoverian shore, and several thousand acres of land have been recovered.

DÖLLINGER, IGNAZ, a German physiologist, born in Bamberg, May 24, 1770, died in Munich,

Jan. 14, 1841. He was professor of physiology at Bamberg, and afterward, when this university was dissolved, at Würzburg. In 1823 he became a member of the academy and a professor of medicine in Munich, and in 1826 professor of anatomy. Among his principal works is *Grundriss der Naturlehre des menschlichen Organismus* (Bamberg, 1805).

DOLLOND, John, an English optician, born in Spitalfields, June 10, 1706, died in London, Sept. 30, 1761. He was descended from a French refugee family, and was originally a silk weaver, but conceiving a passion for the science of optics, he went into partnership with his son as an optical instrument manufacturer. He commenced a series of experiments on the dispersion of light and other subjects connected with the improvement of telescopes and microscopes, the results of which were communicated to the royal society in a series of papers, which appeared in its "Transactions" during the years 1753, 1754, and 1758. These papers were deemed so important by the council of that learned body, that it awarded to Dollond the Copley medal, and in 1761 sanctioned his election as a member of the society. He was the discoverer of the laws of the dispersion of light, and the inventor of the achromatic telescope.—Peter, eldest son of the preceding, born in Spitalfields in 1730, died in Kennington in 1820. Soon after entering into partnership with his father he removed his business from Spitalfields to St. Paul's churchyard, where he met with great success. He made several important improvements in optical instruments, and contributed some valuable papers to the "Transactions" of the royal society, one of which was a vindication of his father's claim to the discovery of the true theory of the refrangibility of light, which appeared in the "Transactions" for 1789. The "Dollond optical establishment" is still flourishing.

DOLOMIEU, Déodat Guy Silvain Tancrède Gratet de, a French geologist, born in the village of Dolomieu, in the department of Isère, June 24, 1750, died in Châteauneuf, Saône-et-Loire, Nov. 26, 1801. While yet very young he killed in a duel a knight of Malta, of which order he was himself a member. He was condemned to death, but the sentence was commuted to imprisonment, and in his dungeon he devoted himself with ardor to the study of the natural sciences. On recovering his liberty he obtained a commission in the army, but did not relinquish his scientific investigations, of which the first fruits appeared in 1775 in his essay *Sur la pesanteur des corps à différentes distances du centre de la terre*, and in two translations into Italian on the subject of mineralogy and of volcanic substances. Made a corresponding member of the academy of sciences, he quitted the military profession and devoted the rest of his life to science. For a series of years he was engaged in exploring Portugal, Spain, Italy, and afterward Egypt, whither he went with Napoleon's expedition. After having completed his survey of the valley of the Nile, he was on the point of exploring the Libyan desert when his failing health compelled him in 1799 to return to France. While on his way to Marseilles, his ship was overtaken by storm and driven into the gulf of Taranto. Seized by the Neapolitans, who at that time were at war with France, he was, in consequence of his former offence against the order of Malta, detained in prison, while the other passengers were after a short time restored to liberty. In the prison of Messina he wrote on the margin of the Bible, with a bone sharpened against the walls for a pen, and the black of his lamp smoke mixed with water for ink—the only writing materials at the prisoner's command—his *Traité de philosophie minéralogique*, and his *Mémoire sur l'espèce minérale*. He recovered his liberty, March 15, 1801, with impaired health; and died soon afterward, while on a visit to his sister. The results of his researches are embodied in his contributions to the *Journal de physique*, *Journal de l'institut*, *Journal des mines*, &c. More than 50 distinct memoirs, many of which contain valuable additions to the knowledge of geology and mineralogy, can thus be traced to his pen, beside his contributions to the *Dictionnaire minéralogique* and the *Nouvelle encyclopédie*. His most interesting essays are: *Mémoires sur le tremblement de la terre en Calabrie; Voyage aux îles de Lipari; Mémoires sur les îles Ponces, et Catalogue raisonné des produits de l'Etna;* and on the nature of leucite, anthracite, pyroxene, &c. The *Journal du dernier voyage du citoyen Dolomieu dans les Alpes* was published by Brunn-Neegaard at Paris in 1802.

DOLOMITE, a mineral species named in honor of the French geologist Dolomieu. It occurs crystallized in rhombohedral forms, and also as a rock of granular and crystalline structure. The mineral species includes several varieties, as brown spar, pearl spar, &c. Its hardness is 3.5–4; specific gravity, 2.85–2.92. The weight of a cubic foot of the rock is consequently about 180 pounds. Dolomite is a magnesian carbonate of lime, consisting of one equivalent of carbonate of magnesia and one of carbonate of lime, or, in 100 parts, 45.65 of the former and 54.35 of the latter. It is usually white, but is also found of various colors. The geological position of the rock is in the primary and metamorphic group. Of these it is an important member, being extensively used for the manufacture of lime, and also as a building stone. It is found abundantly along the eastern part of the middle states, its range extending through the gold region of the southern states, northward, passing near Washington, Baltimore, Philadelphia, thence crossing northern New Jersey, and to the south of the highlands across the Hudson, through western Massachusetts and Vermont into Canada. The rock also occurs at many localities to the eastward of this metamorphic range. The lime made from dolomite varies in quality, not only with the purity of the rock, but also with its tex-

ture, and the manner of burning it. No lime is more highly prized by masons than that made of the close, compact dolomite called the "hard jointer" of Smithfield, R. I. It is perfectly white, is very strong, taking a great deal of sand, and sets quickly. But the same kind of rock of other localities, if burned in the common anthracite kiln, finds little favor with masons from its not slacking uniformly. Lumps of it remain without slacking until after it has been laid upon the walls, where they form blotches, which by the masons is called "pitting out." This is in great measure obviated by a proper method of burning, and particularly by the use of wood or a blazing coal instead of anthracite. Lime of very superior quality has thus been made of the white crystalline dolomite found on the Hudson at Hastings and Sing Sing. Its strength was such as to take about $\frac{1}{3}$ more sand than other limes in use of the best qualities. For agricultural purposes magnesian lime is not in good repute, though the fact of its inferiority does not appear to be well established. As a building stone, dolomite ranks among the best, possessing in a high degree the properties of durability and ease of working. It is obtained in large blocks of sound and uniform texture, with good grain for splitting, and unmixed with foreign matters. But different layers in the same quarry vary greatly in quality, so that care is required in selecting them. The softness of the stone admits of its being easily sawn into ashlar and carved into ornamental mouldings. It forms a considerable part of the white marble used in the construction of the capitol at Washington. The custom house in New York city is built of this stone from the Tuckahoe quarries on the Harlem railroad, and the new custom house at Charleston, S. C., is built of the same from the quarries at Hastings on the Hudson. In England, dolomite has proved so durable and excellent a stone, that a variety of it found at Bolsover moor was selected by the commissioners appointed by the British parliament for investigating the qualities of the various building stones of the kingdom, and choosing from them the best for the new houses of parliament. The choir of Southwell church, which was built of this variety of stone in the 12th century, was found by the commissioners to be in so perfect a state that "the mouldings and carved enrichments were as sharp as when first executed." After describing other examples illustrating the durability of this rock, the commissioners say: "We may here remark, that as far as our observations extend, in proportion as the stone employed in magnesian limestone buildings is crystalline, so does it appear to have resisted the decomposing effects of the atmosphere; a conclusion in accordance with the opinion of Professor Daniell, who has stated that, from the results of experiments, he is of opinion that 'the nearer the magnesian limestones approach to equivalent proportions of carbonate of lime and carbonate of magnesia, the more crystalline and better they are in every respect.'" The following analyses of some of the best of the American dolomites show how near they correspond in composition to the requisite of Professor Daniell:

Marble of	Analyzed by	Carbonate of lime.	Carbonate of magnesia.
Hastings, N. Y..	J. W. Draper, M.D..	52.82	45.78
Sing Sing, " ..	Lewis C. Beck, M.D.	53.24	45.89
Tuckahoe, " ..	" "	61.75	38.25
Roxbury, Vt....	T. S. Hunt.....	53.90	44.04

DOLPHIN (*delphinus*, Cuv.), a cetacean mammal, carnivorous in its habits, and found in most of the seas of the world. The dolphins, as generally restricted, have a convex forehead, and a beak or snout, armed with teeth, separated from the forehead by a well-marked furrow; they do not acquire the dimensions of the whales, being rarely more than 9 feet long. The body is fusiform in shape, without evident neck, and terminated by the horizontal tail common to all cetaceans; the head is not disproportionately large, and both jaws are toothed; there are 2 pectoral fins, and toward the middle of the back there is a fold of the skin which may be called a dorsal fin; the eyes are small, with bare lids; the external opening of the ear is small; the tongue is thick, soft, and but slightly movable; the skin is naked and soft, covered only by a thick mucosity. The teeth are simple, conical, and numerous, varying in number even in individuals of the same species. The cranium is very small compared with the face, concave, and much elevated in front and arched behind; the snout is narrow and elongated from the prolongation of the maxillaries and intermaxillaries, which are not curved forward above; the upper jaw is a little shorter than the lower; the maxillaries extensively overlap the frontals; the tubercles which represent the nasal bones are above the intermaxillaries, resting on the frontals; the parietals are below the maxillaries, and quite on the side; the symphysis of the lower jaw is extensive, and the bone is light and hollow. The cervical vertebræ, 7 in number, are very thin, and united together in the different genera; the dorsals are 13, with as many pairs of ribs, their articular processes becoming effaced by age, commencing posteriorly, and the transverse being about as long as the spinous processes; the lumbar vertebræ are 18, with very long transverse and spinous processes; a sacral vertebra can hardly be said to exist, as the pelvis consists of a rudimentary bone on each side suspended in the muscles; the caudal vertebræ are about 28, gradually decreasing in size, the transverse processes disappearing about the 16th, and the spinous about the 20th; exclusive of the cervicals, there are about 60 vertebræ in all; the V-shaped bones on the under surface of the bodies begin about the 6th caudal. The breast bone is composed of 3 bones, the 1st very wide, grooved in front, and usually pierced with a hole; the shoulder blade is fan-shaped, slightly concave; the clavicle is absent; the pectoral fin is composed of a very short humerus, with a large

upper tuberosity, its lower extremity compressed antero-posteriorly, and uniting by a cartilaginous articulation on an irregular line with the bones of the forearm; the latter are almost rectangular, short and flat, the radius in front and the widest; the bones of the wrist, 6 or 7 in number in 2 rows, form a flat pavement-like surface united by cartilage to the radius and ulna; there is a mere vestige of thumb, according to Cuvier, the index finger being the longest and having 9 articulations with its metacarpal bone and phalanges, the 3d with 7, the 4th with 4, and the 5th a mere tubercle. This anatomical description will answer generally for dolphins and porpoises, and the allied genera. Dolphins are among the swiftest of cetaceans, and their speed is owing to the strokes of the powerful tail; the pectoral fins serve merely to balance and guide the body, and to carry the young. The eye and ear are constructed on the mammalian type; the nasal passages seem destined only for the expulsion of water from the mouth and for the introduction of air into the lungs, and are generally considered as not endowed with an average sense of smell; the allied sense of taste must be very imperfect, and the sensibility of the naked skin low. The teeth are formed only for seizing and retaining prey, which is swallowed whole. Authors differ as to the stomach, some making it single, but most dividing it into 3, 4, or 5 compartments more or less complicated; the intestine is simple, 10 or 11 times as long as the body, and gradually diminishing in size from the stomach to the anus. As the dolphin, like the other cetacea, is not a fish but an air-breathing mammal, warm-blooded, viviparous, and suckling its young, its respiration must be carried on by the usual mechanism of lungs, diaphragm, ribs, and respiratory muscles. Though shaped like fishes, inhabiting the water exclusively, and moving in the same manner with them, it must come to the surface by means of its horizontal tail, and take in air through the single spiracle on the top of the head, which it can do when the mouth is full of water by means of the upward prolongation of the larynx into the nasal passages, and the shutting off of its cavity by muscular action from the mouth and œsophagus; the external opening of the spiracle is guarded by a valve, which prevents the entrance of water when the animal plunges beneath the surface. The water which is taken into the mouth with the food can be made to pass out in a jet from the spiracle, by the closing of the pharynx, and the forcing of the liquid into the nose through the passage in which the larynx is elevated during respiration. Under the skin, in front of the nostrils, are 2 large cavities covered with muscles; into these the water is sent, and remains until the animal chooses to eject it; then, closing a valve at their entrance, the water is sent forth by the contraction of the muscles. The dolphin family make a feeble moaning or plaintive noise, which has often been noticed when they have been stranded alive. The circulation is carried on as in other mammals; only, in order to enable them better to remain under water, there is a plexiform arrangement of the arteries within the chest and near the spine, which serve as reservoirs of pure blood during immersion; these do not communicate directly with veins, and their contents can be taken into the circulation as circumstances require. The reproductive organs are the same as in other mammals, and their functions are similarly performed; the testes are within the abdomen; the prostate gland is large, but the seminal vesicles are absent; the mammæ are 2, with the nipples concealed in a fold of skin, except during lactation, when they protrude on each side of the genital opening. The kidneys are made up of many small glands united. The brain is very wide, the hemispheres however covering only a portion of the cerebellum; the convolutions are numerous and complicated, but narrow; the olfactory lobes seem to be wanting; the cerebellum is well developed, with distinct median and lateral lobes. This great cerebral development affords some ground for the ancient belief in the superior intelligence of the dolphin; the history of this animal, sacred to Apollo, though encumbered with fabulous and superstitious accounts, doubtless contains much truth which whale-hunting moderns have not cared to examine.—As the dolphin family till recently included all ordinary cetaceans with small heads, the divisions which have since been made are very numerous, and no system of classification as yet offered can be called natural; in this condition of cetology, it would be out of place to attempt here to introduce order into this class of animals; such only, therefore, as would not come more properly under whales, porpoises, and other popular titles, will be briefly alluded to; those who wish to pursue the subject into its details can consult the writings of Lacépède, the Cuviers, De Blainville, Lesson, Eschricht, Gray, and others. At the head of the list is the common dolphin (*D. delphis*, Linn.); this, from the shape of the beak, is vulgarly called the "goose of the sea;" it was the *hieros ichthys* (sacred fish) of the ancients, the favorite of Apollo (whose most famous oracle bore its name), and the supposed benefactor of man; it is seen on very ancient coins and medals, and formed a conspicuous object on the coat of arms of the princes of France; from it was named the province of Dauphiné, which gave the title to the heir apparent to the French throne. It attains a length of from 6 to 10 feet, and its proportions are admirably adapted for the speed which is its characteristic. The color is dark on the back, grayish on the sides, and satiny white underneath. The geographical range of this species is extensive, embracing the seas of Europe, the Mediterranean, and the northern and temperate Atlantic; other species are found in the seas of America, Asia, and Africa. Vessels frequently meet them in large numbers, shooting under the bows, springing out of the water, and playfully racing with their

fellows; their speed is such that the swiftest sailing vessel seems stationary beside them. The dorsal fin is about 9 inches high, a little behind the middle of the back; the pectorals, about 2 feet from the snout, are somewhat longer than the dorsal, narrow and rounded; the tail is crescent-shaped, with a notch in the middle, and about a foot wide; the jaws have from 32 to 47 teeth on each side, according to age, simple, conical, largest in the middle of the series. During rapid motion the tail is bent under the body, and then suddenly brought into a straight line. The dolphin is voracious, living principally upon fish, which it boldly pursues, even into the midst of the fishermen's nets. F. Cuvier is inclined, with the ancients, to consider it an intelligent and docile animal; seeing in the fabulous stories of antiquity the symbols of hidden truth, he thinks an examination of the habits of the dolphin will disclose to naturalists a foundation in fact for the supposed intelligence of this species. In former times the flesh of the dolphin was as much esteemed for food as it is now neglected; in the 16th century its price was so high that it was only seen on the tables of the rich; in the time of Dr. Caius, the founder of the college of that name at Cambridge, a dolphin was thought a worthy present for the duke of Norfolk, who in turn distributed it to his friends, who roasted and ate it with porpoise sauce; in France, the dolphin could be eaten by Roman Catholics, especially during Lent, without sin; at that time all cetaceans were considered fish, though really their flesh was as much meat as that of the ox or sheep; the meat is dark-colored, palatable and nutritious, and is now often eaten by seafaring men on long voyages. The *D. tursio* (Fabr.), the *nesarnak* of the Greenlanders, has a thick body, a flattened, short beak, obtuse teeth, a dorsal fin, and a blackish color, except a small part of the abdomen, which is whitish; it attains a size of 9 to 15 feet, has from 88 to 100 teeth, and inhabits the Atlantic from the shores of Europe to those of Greenland; it is less active than the common dolphin. Another name for it is the bottle-nosed dolphin or whale. Other dolphins are the lead-colored dolphin (*D. plumbeus*, Dussumier), about 8 feet long, of a leaden-gray color, rather sluggish in its movements, with about 136 teeth, found on the coast of Malabar, near the shore, where it pursues the pilchards; the bridled dolphin (*D. frenatus*, Duss.), less than 6 feet long, having on the ash color of the cheeks a black band extending from the angle of the mouth below the eye, found in the neighborhood of Cape Verd; the eye-browed dolphin (*D. superciliosus*, Lesson), about 4 feet long, of brilliant blackish-blue color above, silvery below, with a white streak over the eye, found in the neighborhood of Cape Horn; the *funenas* of the Chilians (*D. lunatus*, Less.), about 3 feet long, with a slender beak, fawn-colored above, white below, with a dark brown cross on the back, in front of the dorsal fin, numerous in Conception bay. Among the *delphinidæ* which would not be better described elsewhere, is the genus *delphinapterus* of Lacépède, having no dorsal fin, and a slender transversely flattened beak, separated from the cranium by a deep furrow. Péron's dolphin (*D. Peronii*, Cuv.) is about 6 feet long, elegant in form and proportions, of a deep bluish-black color above, with the snout, sides, pectorals, abdomen, and part of the tail silvery white; the teeth are about 39 on each side of each jaw; like the rest of the genus, it is found in high southern latitudes. The allied genus *beluga* (Bon.) has an obtuse, conical, and rounded head, without prominent beak, and without dorsal fin. The whitefish, or white whale (*B. borealis*, Less.), is a very swift dolphin, of a beautiful cream-white color and symmetrical shape, not unlike in its general outline the new steamship of the Messrs. Winans of Baltimore, that is, a double cone, of which, however, one end is shorter and less sharp than the other in the cetacean; the length varies from 12 to 20 feet; the teeth, according to Cuvier, are $\frac{9\text{-}9}{9\text{-}9}$; being well covered with fat, it is sometimes chased by coast whalers, especially about the mouths of rivers, where it feeds upon the cod, haddock, flounder, and other fish; it is essentially an arctic species, though it descends to the temperate regions of both hemispheres; it has been seen in the river St. Lawrence as high up as Quebec. The genus *globicephalus* (Less.) includes the *D. globiceps* (Cuv.), commonly called the deductor, social, bottle-head, or howling whale; it resembles the *beluga* in the shape of the head, but differs from it in having a dorsal fin; the length is from 16 to 24 feet, and the general color of a shining jet black; the teeth are from 20 to 28 in each jaw; its favorite resort is the northern temperate ocean, in both hemispheres; it is included by Dekay in the fauna of New York; it is remarkable for its sociable disposition, herding together in great numbers, apparently following a leader, and easily driven upon beaches; the proper name is *globicephalus melas* (Less.); some species of the genus have been found in the Mediterranean. The grampus and the porpoise will be described under their respective titles. The heterodons of De Blainville, in which the teeth are absent or very few, though belonging to the *delphinidæ*, are generally called whales, and will be better introduced with them; they include the genera *diodon* (Linn.), or 2-toothed whales, *hyperoodon* (Cuv.), with protuberances on the palate, *aodon* (Less.), the toothless whale (by Gray considered synonymous with the last), and *monodon* (Linn.), or narwhal. The long-beaked dolphins (*delphinorhynchus*, Lacép.) are distinguished by having a prolonged snout, thin and narrow, not separated from the cranium by a furrow; the straight jaws are furnished with numerous sharp teeth, and the dorsal fin is single; some of the species attain the length of 36 feet. The best known species (*D. micropterus*, Cuv., and *D. Sowerbyi*, Desm.) is remarkable for the snout being 4 times the length of the cranium,

and for the curvature upward and forward of the posterior part of the intermaxillaries, carrying with them the maxillaries, frontals, and occipital; it is a northern species, and has been found stranded on the English and French coasts. There are 2 remarkable genera of fresh-water dolphins, one of which, the dolphin of the Ganges (*platanista Gangetica*, Gray.), will be described under Soosoo, the Bengalee name. The other is the Bolivian dolphin (*inia Boliviensis*, D'Orb.), found in the tributaries of the Amazon and the neighboring streams and lakes, even to the foot of the Andes; the beak is long like that of the dolphin, but cylindrical, bristled round with strong hairs, and obtuse at the end; the teeth are about 134, resembling incisors in front and molars behind; the body is short and slender, the pectorals large, the dorsal small and behind the middle of the back; the skin is fine and smooth; the average length of the adult is about 7 feet; the color varies from a pale blue to a blackish color above, and is rosy beneath. It comes frequently to the surface, and is comparatively slow in its movements; its food consists almost entirely of fish, which are devoured with the snout above water; it is killed by the natives for its oil. This curious animal seems to form an intermediate type between the carnivorous and the herbivorous or sirenoid cetaceans. The *delphinidæ* are of little value to the whaler, as they are difficult to catch from their speed and strength, and their covering of fat is much less than in the whales. Near the mouths of rivers and on the coasts herds of them are occasionally hunted with profit for their oil and their skins, and in high northern regions even for food. Many genera of *delphinidæ* inhabited the seas during the tertiary epoch, some very like the present dolphins, others very different from them. Their fossil remains are found abundantly in the miocene, pliocene, and diluvial strata of America and Europe. —The name of dolphin was long ago given by Dutch navigators to a scomberoid fish of the genus *coryphæna* (Linn.), inhabiting the Mediterranean and the seas of warm and temperate regions. The genus has no detached finlets, no isolated dorsal spines, and no armature on the tail; the body is moderately long, more or less compressed, and covered with small scales; there is a single dorsal fin, with flexible rays, extending from the head to near the caudal; the ventrals are thoracic. The generic name is derived from κορυφη, summit, in reference to the elevated shape given to the forehead by a bony crest of the interparietal and frontal which rises between the intermaxillaries and extends to the occiput; this gives a trenchant aspect to the head, with a very convex facial profile; the eyes consequently seem low. The mouth is large, having card-like teeth on the jaws and palatal bones. The dolphin of the Mediterranean, so famous for the beauty of its colors when dying, is the *C. hippurus* (Linn.). Most writers, and especially the poets, have followed the Dutch error as to the name of this fish, and the term dolphin by sailors is taken away from the cetacean and given to the scomberoid. This species grows to the length of about 5 feet; the colors are bluish green above, with azure and golden reflections, and citron yellow below, with pale blue tints; the pectorals are partly leaden and partly yellow, the ventrals yellow below and black above, the anal yellow, and the iris golden. In the Atlantic is the *C. equisetis* (Linn.), with a shorter body and more elevated head. On the coast of South America is the *C. dorade* (Val.), from the name given to the genus by the Portuguese. About a dozen other species are described in different parts of the globe. They are exceedingly active, strong, and voracious, pursuing the flying fish, forcing them to leave the water, and seizing them as they descend into it again. Their beauty is not confined to the dying state; when following vessels, as they often do, nothing can be more beautiful in a calm sunny day, in the clear water of mid ocean, than to see these brilliant creatures darting around the vessel, displaying their ever-varying tints of golden, blue, and green, with every movement. They gather around any floating object, and are readily caught by a hook or harpoon; when brought upon deck the beautiful play of rapidly changing colors commences, which has caused the poet to say:

> Parting day
> Dies like the dolphin, whom each pang imbues
> With a new color as it gasps away,
> The last still loveliest, till 'tis gone, and all is gray.

These colors are produced, as in the chameleon and the cuttle-fish, by changes in the surface by muscular action, as may be seen by the constant undulation of the long dorsal fin. (See Chameleon.) The flesh of this fish is considered good food; it is white, though rather dry. Sailors have an idea, which is probably true, that it is sometimes unwholesome and even poisonous, and they are in the habit of boiling a piece of silver money with the fish to detect the fact; if the piece be tarnished by the boiling, the fish is rejected; if it remain bright, it is considered fit for the table.

DOMAIN, or Demesne (mediæval Lat. *domanium*, the dominion of the lord), in England, lands retained by the great landed proprietors for their own use; the *terræ dominicales* or demesno lands being occupied by the lord or *dominus manorii;* the other or tenemental lands being distributed among the tenants. The demesne lands of the king, *terræ dominicales regis*, which were at an early period very large, and to which additions were made by forfeitures and otherwise, had been, at the time when Blackstone wrote, almost entirely alienated; but as a portion of them were not conveyed absolutely in fee, but upon long leases, they will revert to the crown upon the expiration of those leases. The principal importance of the royal demesne lands grows out of certain incidents that at an early period attached to the estate of the tenants of those lands. The tenure by which such estates were held is designated by old writers as ancient demesne; and to some extent it still continues to

exist. Strictly, lands so held were copyhold, and as such were excepted by the statute 12 Charles II. c. 24, by which military tenures were abolished. One incident, showing that the tenure was originally a species of villenage, is that the lands do not pass by the common conveyances, but by surrender to the lord in the manner of copyhold estates, for certain uses mentioned in the surrender, and a new grant by the lord in pursuance thereof to the *cestuy que use*.—The public domain of the United States is almost beyond calculation. According to the report of the secretary of the interior, made in Dec. 1858, there were on Sept. 30, 1858, on sale at the different land offices over 80,000,000 acres of land, and an additional amount of nearly 62,000,000 acres had been surveyed, and was ready to be brought into market. Prior to the same period more than 55,000,000 acres had been selected and reported as inuring to the several states under acts of congress of 1849 and 1850, granting to such states the swamp and overflowed lands within their respective limits, to enable said states to reclaim them for cultivation.—In France, the term domain is applied to all public property, whether personal or real, which is classified as follows: 1, *domaine de l'état*, which includes highways, harbors, fortifications, forfeited estates, &c.; 2, *domaine* or *dotation de la couronne*, to which belong palaces, gardens, forests, farms, crown jewels, and the like; these constitute the separate property of the crown, but are inalienable; 3, *domaine privé*, the private estate of the sovereign, which he holds and can dispose of the same as any subject, by will or otherwise; but if not disposed of at his death, it is merged in the domain of the crown and passes to his successor.

DOMAT, or Daumat, Jean, a French jurist, born in Clermont-Ferrand, Nov. 30, 1625, died in Paris, March 14, 1696. For 30 years he was king's advocate at Clermont. His great work was published in 1694, under the title of *Lois civiles dans leur ordre naturel* (English translation by W. Strahan, 2 vols. fol., London, 1737; edited by L. S. Cushing, 2 vols. 8vo., Boston, 1850). Domat is called by Victor Cousin "incomparably the greatest jurisconsult of the 17th century," and by Boileau "the restorer of reason to jurisprudence." The intimate friend of Pascal, and his associate in many of his experiments in natural philosophy, he was distinguished for his taste for mathematics and philosophical pursuits as well as for his legal attainments.

DOMBROWSKI, Jan Henryk, a Polish general, born in Pierszowice, Aug. 29, 1755, died in Winagora, June 26, 1818. He entered the army under Prince Albert of Saxony in 1770, afterward joined the Polish forces commanded by Prince Joseph Poniatowski in the campaign against the Russians in 1792, served with distinction in 1793, took part in the insurrection of 1794 under Kosciuszko, but was compelled to surrender after the fall of Warsaw. Having rejected flattering offers from both Russia and Prussia, he accepted a commission from the French directory in 1796 to enroll a Polish legion at Milan, and after serving with honor in the Italian campaigns under Napoleon, Gouvion Saint Cyr, and Masséna, entered the service of the Cisalpine republic in 1802. In 1806 he joined Napoleon at Berlin, published a famous proclamation calling upon the Poles to rise, and soon entered Warsaw in triumph at the head of two national divisions. In the battle of Friedland, to the favorable issue of which he greatly contributed, he was wounded; in 1809 he fought with Poniatowski against the Austrians; in the Russian campaign of 1812 he commanded a division of the grand army; in 1813 his Poles fought bravely in Germany, particularly at Leipsic; and on the creation of the kingdom of Poland he was raised by the czar Alexander to the rank of general of cavalry and senator palatine. He left his memoirs to the society of the friends of science at Warsaw. His name is inscribed on the *arc de l'étoile* at Paris.—His son, Bronislaw, took part in the Polish insurrection of 1848 in the duchy of Posen.

DOME (Gr. δομος, δωμα, building; Lat. *domus*, a house; mediæval Lat. *doma*, a cupola), a concave covering to a building or part of a building. The Italians apply the term *il duomo* to the principal church of a city, and the Germans call every cathedral church *Dom;* and it is supposed that the word in its present English sense has crept into use from the circumstance of such buildings being frequently surmounted by a cupola. Some writers on architecture restrict the term dome to the convex surface of the roof, and cupola (It. *cupo*, deep) to its concave part. The dome may be a segment of a sphere, spheroid, ellipse, polygon, or any similar figure, but in all cases every horizontal section should have a common vertical axis; it is called surmounted when it rises higher than the radius of its base, surbased or diminished when its height is less than the radius of its base. The thickness should increase toward the base, where the structure is weakest, and where the spreading force of the superincumbent weight tends to burst the dome outwardly. To counteract this pressure, iron hoops or chains are often employed. When built of stone the dome is stronger than the arch, as the tendency of each of its parts to fall inward is resisted not only by the parts above and below it, but also by those on each side. The constituent pieces are formed somewhat like the frustum of a pyramid, so that when placed in their positions their 4 angles may point toward the axis of the dome. Each course is thus self-supporting, and not only may the whole be constructed without centring, but an aperture, called the eye, is frequently left in the top without damage to the security of the structure.—The dome seems to have been invented by the Romans or Etruscans, and in the time of Augustus was a common feature in Roman architecture. There is no proof that the Greeks or Egyptians had any knowledge of it, nor is it found in any of the early monuments of Hin-

dostan, but after the Mohammedan invasion of India it was generally adopted in that country. The grandest dome that has remained to us from antiquity is that of the Pantheon at Rome, which, though nearly 19 centuries have passed over it, retains all its stability and magnificence of proportions. Its exterior presents the appearance of a truncated segment of a sphere, considerably less than a hemisphere, and has a circular opening in the top 28 ft. 6 in. in diameter. The base consists of a large plinth, with 6 smaller ones above it. It appears that originally there were flights of steps at intervals all around the dome leading up to the eye, but only one such means of ascent is now visible, the others having been covered with lead. The interior is a hemisphere of about 71½ ft. radius, and the distance from the floor to the top of the dome is equal to the diameter. The thickness is 17 ft. at the base, 5 ft. 1½ in. at the top of the highest plinth, and 4 ft. 7 in. at the eye. The ceiling is ornamented with 5 rows of quadrilateral compartments converging toward the top, each large compartment having 4 smaller ones sunk one within another, which were probably once ornamented with plates of silver or covered with bronze. The dome is built of brick and rubble, and rests on a circular wall 20 ft. thick. The baths of ancient Rome afford many examples of this kind of roof: those of Diocletian had 3 domes, 2 of which remain; and those of Titus are crowned by 2, each 84 ft. in diameter. Near Pozzuoli may be seen an ancient circular building with a dome of volcanic tufa and pumice stone, and the temple of Minerva Medica had a polygonal dome of 10 sides, constructed of pumice stone and brick. That of the famous church of St. Sophia at Constantinople was built in the reign of Justinian, with the professed design of rivalling the glory of the Pantheon. The plan of the church was a cross, and at the angles of the square where the transepts cut the nave, the architect placed 4 columns at a distance of about 115 ft. apart, and over them threw arches. The triangular spaces at the corners were then filled up to a level with the extradoses of the arches, and on the ring thus formed the dome was built. In ignorance of the principle of hooping, the builder resorted to various expedients to resist the lateral pressure of the superstructure, and after it had twice fallen in, was obliged to fill up the large arcades on the N. and S. sides with 3 tiers of small arches. This dome was destroyed by an earthquake a few years after its completion. The present one is of nearly the same diameter (115 ft.), 40 ft. high, supported by corbellings at the angles of the square, and encircled by a row of windows with exterior columns. It is surmounted by a lantern. The church of St. Mark at Venice, built about 973, has 5 domes; the central one, which is much larger than the others, was hooped with iron in 1523. The dome of San Vitale at Ravenna consists of a hemisphere resting on an octagon with 8 piers at its angles, and a window on each face. The great dome of the church of Santa Maria del Fiore, the cathedral of Florence, was begun by Arnolfo di Lapo or Arnolfo di Cambio da Calle about 1298, but after the death of the original architect about 1300 no one could be found for 120 years to finish his work; it was finally undertaken by Filippo Brunelleschi, who brought it nearly to completion. He improved somewhat upon the original design by carrying up perpendicular walls in the shape of an octagon to a height of 175 ft., and upon these placing 2 concentric domes, the internal one being 138 ft. 6 in. in diameter and 133 ft. 6 in. high, from the top of the internal cornice of the supporting walls to the eye of the lantern. This is the first double dome with which we are acquainted. That of St. Peter's at Rome, the grandest in the world after that of the Pantheon, is also double. It stands upon 4 piers, each 61 ft. 11 in. high and 30 ft. 10 in. thick, from which spring arches supporting corbellings finished by an entablature. The entablature upholds a plinth, circular within and octagonal without, and on the latter rests a circular stylobate 28 ft. 6½ in. thick and 12 ft. 4½ in. high, divided into 3 parts by passages, forming flights of steps communicating with 4 spiral staircases in the thickness of the wall of the drum, which rises immediately from the stylobate. The drum is pierced with 16 windows, between which are a corresponding number of solid buttresses 51 ft. 6 in. high. Above it is placed a circular attic 19 ft. 2½ in. in height, and on this rests the great double dome, the internal diameter of which at the base is 138 ft. 5 in. and the external 148 ft. To the height of 27 ft. 8 in. the dome is solid. Its curve describes externally the arc of a circle whose radius is a little over 84 ft., and its height from the attic to the top of the internal dome is 83 ft. 10 in. It is pierced outwardly by 3 rows of small windows and strengthened by 16 projecting vertical bands. The whole is crowned by a lantern resting on a platform surrounded by an iron railing and having a cross on the top, the height from the external plinth of the dome to the cross being 263 ft. The top of the cross is 430 ft. above the ground line. This great work was planned by Michel Angelo, who died before its completion, and was finished under the pontificate of Sixtus V., who caused the exterior to be covered with lead, and the bands with bronze gilt. Owing to the haste with which the work was pushed forward the domes settled vertically in many places, and the band of iron around the inner dome was broken. Six iron circles were consequently placed around the outer dome, secured in their places by iron wedges, and the fractured hoop was repaired. The dome of St. Paul's, London, built by Sir Christopher Wren, is double, and rests on an attic and a drum placed on 4 great arches over the intersection of the 4 naves. The external dome is of wood, covered with lead, and ornamented with panels formed by projecting ribs. It is surmounted by a lantern supported on a conical tower terminated by a spherical dome. The height of the tower

is 86 ft. 9 in., and that of the whole structure from the ground line is 365 ft. The diameter of the dome is 145 ft., and its internal height from the springing 51 ft. The dome of the Pantheon (or St. Geneviève's) at Paris is entirely of stone, and is supported by 4 triangular piers rising from the centre of a Greek cross. It is triple, having beside the inner and outer vaults an intermediate structure built for the purpose of carrying the lantern. The internal dome is 66 ft. 8½ in. in diameter at the springing; the external 77 ft. 8¾ in. The height of the edifice above the ground line is 190 feet. The new reading room of the British museum, opened in May, 1857, is covered by a magnificent dome 140 ft. in diameter and 106 ft. high. It is built principally of iron, with brick arches between the main ribs supported by 20 iron piers. Between the vaulting and the exterior covering of copper a space is left for the equalization of the temperature, and between the vaulting and the inner decorated ceiling there is a similar air chamber for purposes of ventilation. There are 20 large windows around the base of the dome, and an eye in the top 40 ft. in diameter. The new cast-iron dome of the capitol at Washington has a height of about 55 ft., and an internal diameter of 94 ft. 9 in. The height of its ceiling from the floor of the building is 200 ft. The exterior of the structure presents a peristyle 124 ft. 9½ in. in diameter, with columns 27 ft. high, from which springs an attic 44 ft. high, supporting the great dome of a semi-ellipsoidal form, the top of which is 230 ft. above the pavement. Above this rises a lantern, 52 ft. high and 17 ft. in diameter, crowned with a bronze statue of Freedom 18 ft. high. In the interior there is a vertical wall raised upon the cornice of the rotunda, with a panel 9 ft. high richly sculptured; above this is a series of attached columns and large windows, and above these springs a dome which, contracting to a diameter of 65 ft., permits a second dome, 73 ft. in diameter, resting also on a colonnade, to be seen through the opening.—Domes are sometimes made convex below and concave above, in which form they take the name of Moresque, Turkish, or Hindoo. In Russia they are very frequently built of a bulbous shape, somewhat like an onion. The Isaac's church at St. Petersburg, built by the czar Nicholas, is surmounted by an iron dome covered with gilded copper, with a small rotunda rising from its centre.

DOMENICHINO, or Domenico, Zampieri, an artist of the Bolognese school, born in Bologna in 1581, died in Naples, April 15, 1641. His first master was Dionysius Calvart, from whose tyranny he took refuge in the school of the Carracci, of which, in spite of a natural timidity and a slowness which his fellow pupils attributed to stupidity, he was eventually considered the most distinguished pupil. Nicolas Poussin even ranks him next to Raphael. He lived apart from men, and rarely went abroad save to make studies for future use. After studying the works of Correggio at Parma, he joined his master, Annibale Carracci, at Rome, and assisted him in decorating the Farnese palace. He soon after received commissions from Cardinals Borghese, Farnese, Aldobrandi, and others, for whom he painted works which increased his reputation, but unfortunately raised about him a host of enemies whose bitter persecutions rendered his life miserable. His celebrated picture of the "Communion of St. Jerome," now in the Vatican, which has been called second only to Raphael's "Transfiguration," was discovered to bear a slight resemblance to a composition on the same subject by Agostino Carracci, and Lanfranco, a former fellow pupil, took advantage of the fact to decry the picture and the artist. Domenichino was finally compelled by the jealousy of his rivals to retire to Bologna, whence he was recalled by Gregory XV. in a few years to become principal painter and architect in the pontifical palace. He here renewed his triumphs, and at Naples, whither he was invited to paint the chapel of St. Januarius, increased his reputation. His enemies, however, left him no peace, and he died before the completion of his work, not without suspicion of poison. Among his chief works are the "Four Evangelists," in S. Andrea della Valle at Rome; "Adam and Eve," the "Martyrdom of St. Agnes," and "Diana and her Nymphs." His fresco paintings, of which the scenes from the life of the Virgin in the Duomo at Fano are the best specimens, are admirable. His landscapes, although of rather a decorative character, are uniformly good. He never wholly freed himself from the mannerism of his school, and was defective in invention; but in artlessness, in the free conception of nature, and in the expression of emotion, he approached nearer Raphael and his contemporaries than any of the eclectics. Many of his works have been engraved by Raphael Morghen and others.

DOMESDAY (or Doomsday) BOOK, or Book of Winchester, a register of the lands of England, framed by order of William the Conqueror. According to some historians it was begun in 1080 or 1083, according to others at the close of 1085; the book itself records its completion in 1086. Persons called the king's justiciaries visited in person or by deputy the greater part of the kingdom, and obtained the required particulars on oath from the sheriffs, lords of manor, parish priests, reeves of hundreds, bailiffs, and villeins of each vill. The record contained a list of the bishops, churches, religious houses, great men, king's manors, king's tenants *in capite*, and under tenants; the particulars of the name of each place, its holder, its extent, the extent of wood, meadow, and pasture, the ponds and mills, the quantity of live stock, the value of the whole, the homages of each manor, the number of villeins, *cotarii*, *servi*, and freemen, and how much each freeman or soc-man had. Three estimates of the estates were made, viz.: as they were in the time of Edward the Confessor; as they were bestowed by William; and as they were at the time of the survey. The jurors were, more-

over, required to state whether any advance could be made in the value. The returns of the justiciaries were sent to Winchester, and being there digested were entered in 2 volumes, which were carried about with the king and great seal, or deposited in a chapel or vault of the cathedral called *Domus Dei*. From the last circumstance the name Domesday is thought by some to be derived. Others ascribe it to a parallel drawn between the decisions of the book and those of the day of doom. The first volume, called the "Great Domesday," consists of 382 folio pages closely written on vellum, and contains the survey of 31 counties; the second, or "Little Domesday," is in quarto, of 450 pages, and comprises the returns from Essex, Norfolk, and Suffolk. It has also a list of "invasions," or lands possessed without royal authority. Neither Northumberland, Cumberland, Westmoreland, nor Durham appears in the record, for which various reasons are assigned. Other counties are described, either wholly or in part, under adjacent divisions. No account is given of Winchester or of London. As a census of the population the Domesday book is of no value, but with regard to the ancient tenure of lands its authority is supreme. It names only 1,400 tenants *in capite* and 8,000 under tenants, and mentions a total population of 282,242. The book is now preserved in the chapter house at Westminster. A facsimile of it was published by order of government in 1783, having been 10 years in passing through the press, and in 1816 the commissioners on public records published 2 supplementary volumes, one containing a general introduction to the survey with indexes, and the other the 4 similar records called the "Exon Domesday," the *Inquisitio Eliensis*, the *Liber Winton*, and the "Boldon Book," or survey of Durham. The last of these was made by Bishop Hugh Pudsey in 1183; the *Inquisitio Eliensis* is of the 13th century; the others are contemporary with the Domesday book. In the exchequer office there are 2 other large volumes under the latter title, which are merely abridgments of the original register. Many interesting particulars relating to the survey are found in Kelham's "Domesday Book illustrated" (8vo., London, 1788); and a work on the same subject has lately been published by Mr. James F. Morgan ("England under the Norman Occupation," London and Edinburgh, 1858).

DOMICILE, the place where a man is deemed by law to reside, which is not always the place of his actual residence. There has been much confusion and even conflict of judicial opinion as to what constitutes a domicile. The difficulty has arisen from the application of the term in various relations involving diverse considerations of public policy. Instead, therefore, of attempting to institute a general rule which shall comprehend all the different senses in which the term is used, which is clearly impracticable, we shall limit ourselves to an exposition of the principles by which the question is determined in different cases.

1. It is recognized as a general rule that a person who is residing in a foreign country for commercial purposes will be deemed a subject of that country in respect to all the incidents of that relation, as regulated by the laws of nations, in time of war, whether the country of his residence be belligerent or neutral. Thus, if he reside in a country which is at war with another, his property will be lawful prize as belonging to a belligerent; or if the country be neutral, he is entitled to the privileges of a neutral in respect to *bona fide* trade. The residence which gives this neutral right is sometimes spoken of as a domicile, but it is obvious that the term as thus used has no other meaning than actual residence and engagement in business, which it will be seen will not *per se* constitute a domicile in respect to other legal incidents. A single exception is made in the case of a person who leaves his own country *flagrante bello*, it being thought inconsistent with his natural allegiance that he should be permitted to enter into neutral relations with the enemy after war had actually commenced. Upon the same principle greater strictness would probably be insisted upon in regard to the nature of the residence when the question was between the emigrant and his native country, even if he went abroad before the breaking out of hostilities; yet it is difficult to see how it could even in that case be required that a domicile should have been acquired other than results from actual residence abroad for *bona fide* business purposes.
2. In the class of cases where the question is as to the civil rights of a foreign resident, or the legal rule applicable to his property, it becomes necessary to ascertain with certainty the domicile. Thus, in case of intestacy, the distribution of his property will not be according to the laws of the place where he may be temporarily abiding, but will be determined by the law of the place of his domicile; and the best test where that is to be found is by assuming it to be where it is shown to have been at any former period until a new domicile is proved to have been substituted. The cases are often exceedingly difficult of distinction, and it is more usually a question of fact than of legal construction. The intention is what must determine, but this is for the most part to be got at only by incidental circumstances, and the reported cases have been decided, each upon their own circumstances, without furnishing any positive test of general application. The rule of the civil law that a man may have two domiciles, as where he resides a part of the year in one place and a part in another, or where he is carrying on business in two places, is repudiated in England and in the United States, though it was said by Lord Loughborough in the case of Bempde *vs.* Johnstone (3 Vesey, 198), that if the question were an open one, it admitted of a good deal of argument, whether in case of a person dying intestate and leaving property in two different places, it would not have been the better rule that the law of each place should control in the distribution of the property situated there. Nor is

the definition of domicile in the civil law of much practical use in the present changed relations of business and habits of life, although still retained by continental European jurists, and often quoted in English and American cases: *Ubi quis larem rerumque ac fortunarum suarum summam constituit, unde non est discessurus si nihil avocet, unde cum profectus est peregrinari videtur, quo si rediit peregrinari jam destitit.* (Cod. 10, 39, 1; Dig. 50, 1, 27.) It should be remarked that the law of the domicile is to be understood as affecting only personal property; real estate is subject to the law of the place where it is situated. So also the law of the domicile applies to the disposition of property by testament or otherwise, as well as to distribution upon intestacy. If a testament is executed according to the law of the place where a man is domiciled, it is sufficient to dispose of his personal property in another country, although not executed in the form required by the law of such country. In cases of insolvency, the distribution of assets will also be according to the law of the domicile; or rather the assets will be transmitted to the country of the domicile for distribution, except that the domestic debts, that is to say, such as are due in any place where the property of the insolvent is situated, will be first provided for; but it is not entirely settled whether they shall be preferred for the full amount, or shall be entitled only to the distributive share allowed by the law of the domicile. 3. In respect to what may be called statutory non-residence and the remedies given to creditors in such case, there is a good deal of confliction. Thus, in the state of New York an attachment may be issued against the property of any person not a resident of the state for the purpose of making distribution among the creditors generally. (2 Rev. Stat. 3.) Again, by the code an attachment may be issued in a suit against a defendant not a resident of the state, in which case it inures to the sole benefit of the plaintiff in the suit. (Code, § 227.) The apparent intention in both these cases was to provide a remedy where from the absence of the debtor there was none by the usual course of proceeding, and the question of domicile does not seem to be involved. Yet it has been held by some of the courts that a man who is daily in the city of New York attending to business, but goes at night to an adjoining state, and has his family there, is a non-resident within the meaning of the statute.

DOMINANT, in music, a name sometimes given to the 5th note or tone of any scale. The term is also used for dominant chord, or the common chord of which the 5th of any key or scale is the fundamental tone.

DOMINIC DE GUZMAN, a saint of the Roman Catholic church, founder of the order of preaching friars, born in Calavega, in Old Castile, in 1170, died in Bologna, Aug. 6, 1221. His lineage was illustrious. At the age of 14 he was sent by his uncle, the archpriest of Gumiel de Izan, to the school of Palencia, where he remained 10 years in the practice of strict asceticism. Martin de Bazan, bishop of Osma, summoned the young scholar to assist him in the reform of his diocese. Nine years were spent by him in preaching, exhortation, and correction of irregularities. This charge did not, however, confine Dominic to one place. He executed numerous missions, taught theology and hermeneutics in the university of Palencia, and in the quality of archdeacon visited the various churches in his province. In 1203 he was the associate of the bishop Diego, successor of De Bazan, in a diplomatic mission. The king of Castile, wishing to marry his son to the daughter of a northern prince, sent the bishop of Osma to negotiate the matter. The mission was successful, and on their return to Spain the same parties were designated to conduct the bride and her party to her new home. Her unexpected death defeated the plan, and instead of leading in a bridal journey, Diego and his friend could only follow a funeral. The course of their journeys had taken them through the land of the Albigenses, of whose number and obstinacy they had frequent evidence. So deep was their sense of danger to the church from this source, that when the death of the princess of Lusignan had rendered their mission fruitless, instead of returning directly to Spain they went to Rome to solicit from Innocent III. leave to remain in France and convert these erring brethren. This was readily granted, and a 2 years' dispensation from his episcopal duties was permitted to the bishop of Osma. Stopping at the abbey of Citeaux on their return, to consult with the monks upon the best way of destroying the heresy, they proceeded to Montpellier, where, in conjunction with the appointed Cistercian dignitaries, they commenced their work. The method of conversion at first followed was public conference. For 8 days Dominic and his friends disputed with the Albigensian teachers near Montpellier, 8 days more at Béziers, and 15 days at Montréal, converting some in every place, and in the last named place 150. According to the Dominican writers, miracles aided them. At Faureau, a writing of Dominic in defence of the Catholic faith, thrice cast into the fire, is said to have been thrice withdrawn uninjured; while a writing of the heretics, thrown in at the same time, was instantly consumed. In 1207 the joint mission of the Spaniards and Cistercians was closed by a conference in the castle of Count Raymond of Foix, whose wife and sisters were Albigenses. Various eminent converts were made; and then the bishop Diego returned to his diocese, and the Cistercian monks went back to their monastery, leaving Dominic in sole charge of the mission. The connection of Dominic with his Cistercian companions had not been altogether harmonious. His method had differed from theirs, and with the violent and sanguinary temper of the legate Peter of Castelnau he had no sympathy. This man was quite ready to employ the secular power in the extermination of heretics, and

when, in Jan. 1208, he was assassinated by a servant of Count Raymond of Toulouse, there were more to applaud the crime than to aid the avengers. The attempt to punish this crime was the signal for a bloody religious war. A new crusade was preached; Innocent urged the kings of France and England to forget their quarrels and combine against the Albigenses; and into the doomed region armies marched such as those which had fought in Syria against the Saracens. Raymond of Toulouse, protector of heretics, was stigmatized as a murderer, and his hereditary foe, Simon de Montfort, was allowed to ravage the province, to hale to death its tenants, and to ruin the heritage of this lukewarm son of the church. How far Dominic took part in these religious wars, is vehemently disputed. According to Sismondi, he directed these persecutions from the beginning. His latest biographers, on the contrary, offer documents to prove that Dominic had nothing to do with any acts of violence. The public opinion of several centuries has assigned to Dominic the fame of founding the inquisition, but his name is not mentioned in the decree of the inquisition which bears the date of 1215, and the special charge of the holy office was not intrusted to the Dominicans until 1233, 12 years after his death. This first crusade against the Albigenses lasted 7 years, from 1208 to 1215, when the surrender of Toulouse and the opening of its gates to the crusaders seemed for a time to close the war. A permanent memorial of Dominic in this period is the institution of the rosary, which has been of universal use among Catholics since his day. More than one before him had prescribed similar methods of prayer and meditation, but his method is the earliest of the kind that still remains in use. The great event of 1215 in the history of the church is the foundation of the order of preaching friars. When Dominic entered Toulouse with 4 associate priests, a rich citizen, Peter Cellani, offered his house for the use of the brethren, and with another citizen, Thomas by name, joined himself to their band; so that there were 7 in all, vowed to labor together for the conversion of souls. When the plan was submitted to the pope, he rather advised the reform of orders already existing. Finally, however, Dominic received permission to make rules for his desired order, although one of the canons of the 4th council of Lateran forbids the creation of any new religious order. The difficulty was evaded by the adoption for the new monastic body of the rules of St. Augustine, modified by the rule of the Premonstratensian convents, and on Dec. 26, 1216, two papal briefs formally established the order of preaching friars. The pope also now created the office of master of the sacred palace, to which he appointed Dominic. It is the duty of this functionary to take charge of all theological matters in the papal mansion, to nominate the preachers, to authorize the books, and to decide all minor questions of doctrine or discipline which may come up in the domestic circle of the pontiff. The duties of this office did not keep Dominic in Rome. He made journeys into Languedoc, into Spain, and as far as Paris, attending everywhere to the consolidation of his new brotherhood. In 1219 he preached in Paris, and so charmed the rude king of Scotland, at that time sojourning in the French capital, that at the request of this monarch, that northern land was added to the field which the preaching friars might occupy. In the same year his most important acquisition was made in the gift of the church of St. Nicholas at Bologna, and the enrollment of a large number of professors and dignitaries as members of the order. Henceforth Bologna became the chief Dominican centre, as it has ever been the goal of pilgrimage to all of the fraternity. Here the alternate general chapters of the order were held. The second chapter (1221) was the last meeting of the order that Dominic attended. His health now began to fail, and after returning from a visit to Venice, he was seized with a dysentery and fever from which he died. His body was buried under the pavement of the church of St. Nicholas, and in 1233 the remains, which were found to be perfect, were transported into the new church and interred in the south transept. The decree of canonization was passed July 4, 1234, and his anniversary is celebrated on Aug. 4. Nicolo di Piso decorated the tomb with bass-reliefs representing the miracles of the saint. Alfonso the Lombard added to them in the 16th century another series, and Michel Angelo crowned the gorgeous monument with a statue of St. Petronius. The church which covers this tomb now bears the name of St. Dominic. In the sacristy is a statue of the saint, carved from the wood of a cypress, which, according to the legend, the hand of the saint himself had planted.—The character of Dominic has been differently judged, according as it has been viewed from a Catholic or a Protestant standpoint. By the one party he is eulogized as a pattern of every virtue; by the other he is condemned as bigoted, cruel, and tyrannical. Commonly regarded as the founder of the inquisition, all the excesses of that tribunal have been imputed to him for guilt. There can be no doubt that he allowed bloodshed which he might have prevented, and that he loved orthodoxy more than peace. His consistency cannot be questioned. He was industrious, frugal, and temperate in his habits, and had a singular faculty of winning and holding the love of his brethren. Of his sermons and commentaries none are preserved, and all that now testifies to his literary or theological powers is the system of rules prescribed to the order, and a few epistles. Frequent allusions are made in the writings of the biographers to his notes upon the psalter, the epistles of Paul, and the Gospel of Matthew, but these are lost beyond recovery.—The life of St. Dominic has been written in Latin by D'Apolda, in Italian by Bottoni, in Spanish by Juan Lopez, in French by Father Touron (Paris, 1739), by the Bollandists, and by several others. See also *Vie de Saint Domi-*

nique, by Lacordaire (Paris, 3d ed. 1844), and *Saint Dominique et les Dominicains*, by Elme Marie Caro (Paris, 1853).

DOMINICA, a British West India island, one of the Lesser Antilles, Leeward group, 29 m. S. of Guadeloupe, in lat. 15° 18′ N. and long. 61° 32′ W.; length from N. to S. 29 m.; breadth 16 m.; area, 291 sq. m.; pop. 22,469 (according to the "American Almanac" for 1859), of whom only a small number are whites, the majority being emancipated slaves. It is of volcanic origin, and when viewed from the sea presents the appearance of a confused mass of mountains. The highest summit has an elevation of 5,300 feet. Dominica is well watered, having upward of 30 rivers and numerous rivulets. It has also sulphurous and thermal springs, and a deep lake on a high mountain 6 m. from Roseau. Interspersed among its mountains are many fertile valleys, with a black and rich soil well adapted for raising every tropical production. In 1850 the imports were valued at £57,656, and the exports at £58,265. The principal exports in 1853 were 65,788 cwt. of sugar, 35,794 gallons of rum, 81,016 of molasses, 67,594 lbs. of coffee, 69,296 of cacao, 3,525 of arrow root, 3,250 of cotton wool, 5,062 gallons of lime juice, and 1,354,020 oranges. The revenue amounted to £7,336 in 1855, and to £12,918 in 1856. The expenditures in the year ending Dec. 1, 1855, were £9,245, and in that ending Dec. 31, 1856, £10,487 (comprising £800 for educational purposes). There are about 10 free schools, but the bulk of the population being Roman Catholics, education is chiefly controlled by the clergy of that persuasion. The property annually created on the island has been estimated at £250,000, and the aggregate movable property at £1,500,000. The woods of Dominica swarm with bees, which produce great quantities of wax and honey. This is the European bee, much larger than the native bee of the West Indies, and must have been transported thither.—Dominica was discovered by Columbus in 1493; and being equally claimed by England, France, and Spain, it was considered a neutral island by those 3 powers till 1759, when it was captured by the English; and it was ceded to England by France in 1763. It was recaptured by the French in 1778, and again restored to England in 1783. Its government is administered by a lieutenant-governor, a council of 12 members appointed by the crown, and an assembly of 19 representatives chosen by the people. Capital, Roseau, on the S. W. side of the island; pop. about 4,000.

DOMINICAL LETTER, the letter denoting Sunday for a given year. The council of Nice, A. D. 325, established the rule that Easter Sunday should be the first Sunday after the full moon which happens upon or next after March 21. For the purpose of determining when Easter falls, and for other similar problems concerning the day of the week and the day of the year, it was early found convenient to place the first 7 letters of the alphabet in succession against the days of the months, putting A to Jan. 1, and repeating the 7 letters as often as necessary until Dec. 31. The letter which falls against the first Sunday in January will fall against every Sunday in the year, and this is the dominical letter for that year, unless it be leap year; and then, as Feb. 29 as well as March 1 is marked D, the dominical letter for the last 10 months of the year will be the preceding letter of the alphabet. To find the dominical letter will manifestly enable you to find what day of the week a given date in the year is. But the dominical letter, being known for any one year, can be found for any other, by simply remembering that an ordinary year is 52 weeks and one day, a leap year 52 weeks and 2 days, so that the dominical letter will go backward from G toward A, one letter for a common year and 2 for a leap year. This gives rise to an arithmetical rule for finding the dominical letter, which may be thus expressed: To the number of the year add ¼ of itself, neglecting fractions, and divide the sum by 7; then for the 19th century subtract the remainder from 8, or, if it is 0, from 1, and the new remainder will indicate the place of the dominical letter in the alphabet; for the 18th century subtract from 7; for the 17th century and back to 1582 subtract from 6, or if the remainder is more than 6, from 13; for dates previous to 1582 subtract from 3 or 10. (But it must be remembered that the dominical letter thus obtained for a leap year belongs to the time after Feb. 29, and that for the preceding 2 months the dominical letter was the succeeding letter in the alphabet.) This new remainder is also the date of the first Sunday in January for that year. The same date in February will fall on Wednesday; in March, on Wednesday; in April, on Saturday, &c.; as may easily be seen from the fact that the first days of the 12 months have annexed to them in the calendar the initials of the words: At Dover Dwell George Brown, Esquire, Good Christopher Finch, And David Friar. For example, the day of the week on which New York was incorporated, June 12, 1665, is thus found: $(1665+416)\div 7=297$, with a remainder of 2; and, it being the 17th century, $6-2=4$, which shows the dominical letter for that year to have been D. Then, as June begins with E, it is plain that June 1, 1665, was Monday, and the 12th was Friday.

DOMINICAN REPUBLIC, the eastern portion of the island of Hayti, comprising nearly ⅔ of the island. Its name is derived from the ancient Spanish appellation of the island, San Domingo. Its area is estimated at 17,500 sq. m. Its population is about 136,000, of whom one-tenth claim to be whites; the rest are of African descent, or of mixed African and European. The boundary between it and the Haytian republic is an irregular line drawn from the mouth of the river Massacre on the north coast of the island to the river Anses-à-Pitre or Pedernales on the south coast. The interior of the republic consists of mountain ranges, rising to an elevation of 6,000 to 8,000 feet, and covered with magnificent tropical forests. From the

base of these mountains large plains, watered by numerous streams, stretch toward the coast. Of these plains the Vega Real (Royal plain), and those of the Jayua, the Azua, and the Neybo, are the most densely populated. Among the rivers, most of which bear the character of mountain torrents, the Great Yaqui, emptying into the bay of Monte Christo, the Yuma, whose embouchure is in the bay of Samana, the Higuey, the Gaboon, Soco, Socaris, Brujuelas, Ozoma, Jayna, Nisao, Bani, and Neybo deserve to be mentioned. The harbor of San Domingo city is one of the best; next to it the bay of Samana offers an excellent roadstead. Of the lesser islands on the coast belonging to the republic, Beata and Saona are the most considerable. The climate, though tropical, is less unwholesome than elsewhere in the West Indies. The soil is exceedingly fertile, but the industry of the inhabitants is not equal to the immense resources of the country. Gold, silver, and iron abound in the mountains, but no mines are worked. Cattle-raising in the level country, and ebony-cutting in the mountainous regions, are the principal occupations of the people, agriculture being mainly confined to the raising of the manioc root, which is used as a substitute for grain. Politically the republic is divided into 5 provinces, viz.: Azua de Compostella, San Domingo, Santa Cruz del Seybo, Concepcion de la Vega, Santiago de los Caballeros. These are also the names of the provincial capitals, of which Santiago de los Caballeros is, next to the city of San Domingo, the most important. The inhabitants are Roman Catholics; an archbishop resides at the city of San Domingo. The army is nominally about 20,000 strong. The navy consists of 2 corvettes, 1 brigantine, and 4 schooners. The seal of state represents a cross, supporting an open Bible, surrounded by arms and the motto: *Dios, Patria, y Libertad.* The language of the people is Spanish. The constitution, like that of most Spanish American republics, is modelled after that of the United States. It provides for a president, to be elected for the term of 4 years, a senate of 5, and a house of representatives of 15 members. The municipalities into which the provinces are subdivided are organized on the basis of self-government. The conditions upon which foreigners may be naturalized are very liberal, and no distinction is drawn in favor of colored persons. Free farms, farming utensils, and provisions for 6 months are offered to settlers. The commerce of the country is as yet limited, owing partly to the deranged state of the circulation and exchanges. The exports from this republic into the United States during the fiscal year ending June 30, 1858, amounted to $109,370, and the imports from the United States to $112,427. The coins are gourdes (piastres, dollars), half gourdes, gourdins (quarters), escalins (eighths), and half escalins (sixteenths).—The present Dominican republic was a Spanish colony until 1795, when, by the treaty of Basel, the whole island was united under French rule. When, after terrible struggles, the colored population of the island had become independent of France, the tyranny of Dessalines drove the Dominicans back into the arms of Spain, which thus regained possession of its former colony in 1808. The next year the Dominicans declared their independence, abolished slavery, and remained in an unsettled state until 1822, when the whole island was united under a republican form of government, and Boyer, the president of Hayti, was chosen president for life. But in 1844, the negroes of Hayti having succeeded in elevating Gen. Rivière to the presidency, the Dominicans, encouraged by the friendly assurances of the French consul-general Moges, again formed a separate government (Feb. 27), under the auspices of the "liberator" Pedro Santana, who defeated Rivière near Santiago (April 9), thus securing the independence of his country. Recognized by France, a treaty of friendship and commerce with which power was concluded, Oct. 22, 1848, and by Great Britain (treaty of amity, commerce, and navigation concluded in May, 1850), the Dominican republic upheld her independence successfully against repeated efforts of Soulouque, the ruler of Hayti. The presidential term of Santana having ended in 1849, Jimenes was elected his successor. Though of Caucasian blood, the latter secretly conspired with Soulouque, who invaded the territory of the republic at the head of 20,000 men, and defeated the Dominicans in some skirmishes near Azua and Las Matas. In this extremity Santana was recalled by the people. He dispersed the Haytian army, April 22, near Savanna Numero, so completely that the war for the time being was at an end. Jimenes sought a refuge with Soulouque, who made him one of his dukes, while Santana resigned his dictatorship in favor of the newly elected constitutional president, Buenaventura Baez. In 1850 Soulouque once more invaded the country unsuccessfully. Baez, having during the latter part of his administration favored the policy of the clerical party, was rejected by the people in 1853, and Santana reëlected president. He compelled the archbishop to swear allegiance to the constitution, and endeavored to free himself from French influence. His sympathies with the United States induced him to enter into negotiations with a secret diplomatic agent of President Pierce, Gen. Cazneau, and to negotiate with him a treaty (Oct. 5, 1854), the secret stipulations of which provided, it is believed, for the cession to the United States of the bay of Samana. But this treaty was never ratified, nor has the Dominican republic ever been recognized by the United States. It is probable that the failure of Santana to obtain this recognition facilitated the efforts of the French and British agents to render him unpopular and once more elevate Baez, now the recognized leader of the clerical party, to the presidency (Feb. 1857). But his triumph was short-lived. Dissatisfac-

tion with his rule spread so rapidly that Santana was enabled to head a revolutionary movement (Sept. 1857), which eventually led to the expulsion of Baez (1858), and the restoration of the liberal rule. In consequence of the downfall of Soulouque in Hayti (Jan. 1859), Santana offered his hearty congratulations to President Geffrard, and it was generally expected that a close alliance would again be established between the two republics.

DOMINICANS (preaching friars, *fratres prædicatores*), a monastic order of the Roman Catholic church, founded in 1215 by Dominic de Guzman, on the rule of St. Augustine and a part of the statutes of the Premonstratenses. Its main object was to labor by preaching for the advancement of the Catholic church and the extermination of heresies, especially of that of the Albigenses. The order received the papal ratification in 1216. At its first general chapter in Bologna in 1220, it renounced the possession of all property, and decreed that none of its convents should receive lay brothers. The constitution which it adopted is strictly monarchical, like that of all the other mendicant orders. The convent is governed by a prior; a combination of several convents, called a province, by a provincial; the whole order by a general, the last to be elected by the general chapter, which is to meet once every year. The extension of the order was very rapid. At the 2d chapter in 1221, France, Italy, Spain, Germany, Hungary, and England were represented. In 1278 the number of convents amounted to 417. The influence and the reputation of the order increased greatly, when in 1233 the pope placed them at the head of the inquisition, which, in Italy, Spain, and Portugal, became gradually their exclusive domain. Though endowed in 1272 with all the privileges of the mendicant orders, they acquired in 1425 the right of receiving donations, and many of their convents became very rich. A new period in the history of the order commences with the establishment of a Dominican professorship of theology at Paris in 1228, which in 1230 was followed by a second. As the Franciscans soon succeeded in securing theological chairs for their order also, that grand theological emulation sprang up between these 2 orders, the history of which is almost equivalent to that of theological literature in general during the latter part of the middle ages, and in which the Dominicans distinguished themselves as Nominalists, Augustinians, Thomists, and opponents of the immaculate conception of the Virgin Mary. Their missionary activity commenced as early as the 13th century in Asia, and, especially in Armenia, many schismatics were converted by them to the Catholic church. In America they protected the natives from being enslaved, and here as well as in the East Indies they exceeded all other orders in power, number, and wealth. They had a controlling influence over the literature of the Catholic church through their prescriptive possession of the office of master of the sacred palace at Rome, and the supreme censorship of books, which is connected with that office. But great losses were inflicted on them by the reformation. In the countries where Protestantism became predominant they lost more than 400 convents, and at many Catholic courts and universities their influence was supplanted by that of the Jesuits. But they still counted in the 18th century more than 1,000 convents of monks and nuns in 45 provinces, 11 of which were out of Europe. By the French revolution they lost all their convents in France and Belgium, nearly all in Germany, and many in Italy. They have since also been suppressed in Spain, Portugal, and Sardinia, but maintained their ground in Sicily, and to a great extent in Hungary and Switzerland. In France they reappeared during the reign of Louis Philippe. The order early relaxed the strictness of its ancient rule. Several attempts to restore it were made in the 15th and 16th centuries, but with only partial and transitory results. On the other hand, there was never a permanent schism in the Dominican order as in that of the Franciscans. When Pius IX. declared the reformation of the religious orders to be one of the principal cares of his pontificate, the Dominicans were among the first with regard to whom the purpose of the pope was put in execution. The efforts of the pope were effectively seconded by the small number of convents which Father Lacordaire, by far the most distinguished member of the order in the present century, had founded in France. The pope suspended temporarily the right of the general chapter to elect a general, and appointed one of the French disciples of Lacordaire, Father Jeandel, vicar-general of the order. Since then the reformation has been carried through in many convents, in some cases not without a violent opposition. In Austria it was commenced in 1857, with the coöperation of the bishops and the government, in the convent of Vienna. The order has also made preparations to enlarge its missionary territory in Asia Minor. There are at present convents in Italy, Austria, France, Belgium, Holland, Ireland, Poland, Russia, Turkey, Asia Minor, India, China, North and South America. In South America the order is on the decline, but it makes progress in North America, and, though slowly, in France. It has given to the church a large number of bishops and archbishops, 66 cardinals, and 4 popes, Innocent V., Benedict XI., Pius V., and Benedict XIII. Among its most illustrious members were Albertus Magnus, Thomas Aquinas, Master Eckard, John Tauler, Henry Suso, Savonarola, Las Casas, Vincent Ferrier, Vincent of Beauvais, and, at the present day, Lacordaire. The habit of the order consists of a white gown, scapular and calotte, and black cloak and pointed hood.—An order of Dominican nuns was established by St. Dominic, in 1206, at Prouille, near Toulouse. The first members were mostly converts from the Albigenses. This order counted at the time of its greatest prosperity about 400 convents in Europe and America, and abandoned the strictness

of the original discipline even sooner than the monks. They took part in the various reforms of the latter, and split into a number of similar congregations. At present they have convents in Italy, France, Belgium, Austria, Bavaria, Switzerland, Poland, North and South America. East Tonquin, in Further India, had, at the beginning of the present century, 25 convents of native nuns, following the rule of St. Dominic, with about 600 inmates; but a great number of them have been dispersed by a cruel persecution. There was also a third order (tertiarians) of St. Dominic, which was called the militia of Jesus Christ, but it is doubtful if they owe their origin to St. Dominic himself. Later, they appear in history under the name of brothers and sisters of penitence of St. Dominic. St. Catharine of Sienna and St. Rosa of Lima were members of this order.

DOMINIS, Marc' Antonio de, a theologian and natural philosopher, born in Arbe, on the coast of Dalmatia, in 1566, died in Rome in Sept. 1624. He was a relative of Pope Gregory X., studied at Loretto under the direction of the Jesuits, and became a member of their order. He taught mathematics and philosophy with great success in several of the large cities of Italy. After being for 20 years a member of the society of Jesus, he left it in order to become a bishop, and was appointed in 1602 to the archbishopric of Spalato, and to the primacy of Dalmatia and Croatia. He now began to oppose some of the measures of the court of Rome, and his writings were condemned by sentence of the inquisition. This gained for him the sympathies of Protestants, by whom he was induced in 1616 to pass into England, where he became useful to James I. He embraced Protestantism, was made dean of Windsor, and though his avowed aim was to effect a reunion of the 2 great divisions of Christendom, he wrote and preached with vehemence against Roman Catholicism. In his work *De Republica Ecclesiastica*, which he published in England, he maintained that the papacy was a human institution, a temporal monarchy, and was not the divinely appointed Christian church. This book was immediately censured by the theological faculty of Paris, and burned by order of the inquisition. Loaded with tokens of friendship and esteem by the king and clergy of England, he suddenly reverted to his former theological views; and wishing to signalize his return to Catholicism by a brilliant action, he ascended a pulpit in London, and retracted all that he had ever written against the Roman Catholic church. He was immediately banished from England, and repairing to Rome abjured his apostasy before a public consistory. His inconstant humor did not long leave him in repose, and it was soon discovered that he had repented his last conversion, and was meditating a return to Protestantism. He was imprisoned by Pope Urban VIII., and his sudden death soon after caused the report that he was poisoned; being convicted of heresy, his body was disinterred and burned along with his writings. His chief philosophical work is entitled *De Radiis Visus et Lucis*. Newton ascribes the first suggestion of the true explanation of the rainbow to this work.

DOMINO (It.), a hood and cloak enveloping the entire person, and worn at masked balls as a disguise. It originally designated the camail, which was the ordinary robe of ecclesiastics in the winter, and the name was borrowed by the maskers from the resemblance of their disguises to the clerical attire.

DOMINOS. This game has been traced by some authors to the Greeks, Hebrews, and Chinese. Its first appearance in western Europe, however, is not ancient, it having been introduced into France from Italy about the middle of the last century. It is now played in all the *cafés* of France, and less commonly in the taverns of England and America, and is a favorite pastime of small social circles. The domino is a small flat oblong of ivory or bone, divided on one side by a line into 2 compartments. Each of these is marked with a certain number of dots, from 1 to 6, or is left a blank, so that upon each domino there is a different combination of numbers. The game is played with 28 dominos, the reverse sides of which are unmarked and all alike. This side being up, each player takes an equal number of the dominos. The person who has drawn the one which has the highest number of points puts it down; the next domino played has to be one with a number the same as one of the 2 numbers presented by the first, and the 2 similar ends are joined. The third player may match the remaining number of either the first or the second domino, and thus the game continues till one of the players has put down all his pieces. The combinations of this game are neither very varied nor intricate, and yet it requires, though in a less degree than many other games, memory and calculation.

DOMINUS (Lat. lord, master), an ancient title of honor prefixed to the name of the person who bore it, who was usually either a knight or a clergyman. It was, however, sometimes given to gentlemen who were not knights, especially if they were manor lords. The title is applied at the present time in Holland to ministers of the Reformed church.

DOMITIAN, Titus Flavius Augustus, a Roman emperor, born Oct. 24, A. D. 51, murdered Sept. 18, 96. He was the younger son of Vespasian, and narrowly escaped death at Rome by concealing himself when his father was proclaimed emperor by the legions of the East. On the fall of Vitellius he ruled the capital as Cæsar till the return of his father. Having exhibited in that short period a sanguinary and licentious temper, he was excluded both by Vespasian (69–79) and Titus (79–81) from all share in public affairs, and spent his time on an estate near Rome, in effeminate pleasures, as well as in writing and reciting poetical compositions. On the death of Titus, which was ascribed to him by the people, he was hailed emperor by the sol-

diers. At the beginning of his reign he concealed his vices, and even displayed some firmness in the regular management of affairs; but this was of short duration. An outbreak in Germany brought his bloodthirsty disposition into full activity, and from that time the victims of his fear or wounded vanity were numberless. In his wars he was personally unsuccessful against the Chatti and other German tribes, as well as against the Dacians, whose king Decebalus compelled him to purchase peace on humiliating terms. These reverses, however, did not prevent him from triumphing and decorating himself with the names of Germanicus and Dacicus. Government officials, says a historian, were busy in keeping the people of Rome from laughing on such occasions. Games were employed to amuse them. Agricola, the heroic commander in Britain, was recalled because of his victories, and the jealousy of his fame probably caused his subsequent death. War having been terminated by an ignominious peace with Decebalus in 89, Domitian satiated his thirst for blood at home, until, as Tacitus says, silent fear reigned at Rome. This historian, the son-in-law of Agricola, has branded the memory of Domitian in eloquent terms. After many conspiracies which were discovered, one succeeded in ending the reign and life of the tyrant.

DOMRÉMY, or Domrémy la Pucelle, a French village, in the department of Vosges, 7 m. from Neufchâteau, on the Meuse, the birthplace of Joan of Arc. The cottage in which she was born has been repaired at the expense of the government and a free school for girls established in it. A chapel has also been dedicated to her and a monument raised in her honor, to which Louis Philippe contributed a cast of the statue of the maid of Orleans executed by his daughter, Princess Marie.

DON, a title of honor, chiefly used among the Spaniards. The corresponding title among the Portuguese is *dom*, the right to which is considered as an especial privilege which no one can assume without the consent of the sovereign. Dom is also sometimes employed in France as a clerical title. The word is derived from the Latin word *dominus*, lord or master. The old English form of the word is *dan*, frequently occurring in Chaucer.

DON. I. A river of Russia, the Tanais of the ancients, and the Tuna, Doona, or Dana of the Tartars. It is one of the largest rivers of Europe. It rises in a small lake in the government of Toola, flows S. E. and S. W., passes Voronezh, Pavlovsk, Novo Tcherkask, Tcherkask, Nakhitchevan, Rostov, and Azof, and, having separated into 3 branches, enters the sea of Azof through channels so shallow that only flat-bottomed boats can pass through them. Its length in a direct line is 468 m., but including windings it is 995 m. In the summer, navigation on the Don is difficult, but in winter the water is high enough for vessels of great size. The course of the river lies through a low country, covered with vast forests of oak and pine. The current is sluggish, and sand banks, over which there are often only 2 feet of water, are of frequent occurrence. The principal tributaries of the Don are the Sosna and the Donetz on the right, and the Voronezh (or Voronetz), the Khoper, the Medvieditza, the Sal, and the Manitch on the left. II. A river of Aberdeenshire, Scotland, next to the Dee in size, but of little commercial importance. It rises on the declivity of Ben Aven, flows S. E. 62 m., and enters the German ocean near the town of Aberdeen. It is navigable for a very short distance from the sea. Near its mouth stands the celebrated one-arched Gothic bridge of Balgounie, mentioned by Byron in one of his early poems. A handsome new bridge of 5 arches has been built a little below the old structure. The salmon fisheries of the Don were lately rented for £2,000 per annum. III. A river of Yorkshire, England, 55 m. long, rising near the borders of Cheshire, and flowing into the Ouse. It is navigable from Sheffield, 40 m., and communicates by canal with the Trent and the Calder.

DON JUAN, a mythical personage, a type of licentiousness and dissipation, accomplished and wicked, represented with all the graces which win woman's heart, and at the same time with all the snares which beguile woman's virtue. According to tradition, the patrician family Tenorio of Seville was the first to produce a Don Juan of sufficiently remarkable character to become the representative man of the order. His life is placed by some legends in the 14th century under the reign of Pedro the Cruel, and by others in the 16th century in the era of Charles V. He is represented to have been in the act of abducting a daughter of the governor of Seville when caught by her father; a duel ensued, in which the governor was the victim. A statue having been erected to the deceased in the family vault in the convent of San Francisco, Don Juan enters the vault, and invites the statue to join him in his revels. The stony guest appears at the banquet to the great amazement of Don Juan, and terminates the festivity by consigning his godless entertainer to the infernal regions. The story was first dramatized at the beginning of the 17th century by the Spanish poet Gabriel Tellez, commonly called Tirso de Molina, under the title of *El burlador de Sevilla, ó el convivado de piedra*. This drama was soon after its publication adapted for the Italian stage, and thence found its way to Paris, where it became the basis of several French adaptations, of which Molière's *Don Juan, ou le festin de pierre*, and Thomas Corneille's production, modelled after Molière's play, are the most celebrated. In England a play written by Shadwell, called "The Libertine," and treating the same subject, was performed in 1676. The subject was not produced on the Spanish stage in its present form till about 1675, when it was rewritten by Antonio de Zamora. This version of Zamora furnished the groundwork of the modern treatment of the

theme. Goldoni published his *Giovanni Tenorio* in the first half of the 18th century. Gluck followed with a ballet in 1765, Vincenzo Righini with an opera in 1777, and Lorenzo da Ponte with the text to Mozart's opera in 1787, which appeared in the same year. This is the masterpiece of this great composer, and at the same time the most remarkable production to which the legend of Don Juan has given rise. Apart from the opera and the drama, the Don Juan literature has found in the present century a new field in the sphere of romance and poetry in Spain and France; while in England the name of Don Juan was adopted by Byron as a congenial title for his famous poem. The 2 characters of Faust and Don Juan are blended in one and the same personage in a German drama by Grabbe, while a great number of plays, novels, and translations from the Spanish on Don Juan abound among German books of the present day. Scheible's *Kloster* (vol. iii., part 2, Stuttgart, 1846) contains a full account of the tradition and literature of the subject.

DONARIUM, a metal discovered by Dr. Bergman in a mineral from Brerig in Norway, and named for the Scandinavian god Donar. The mineral contained a yellowish red substance giving a light orange powder, of hardness between 4 and 5, and specific gravity 5.397. Heated in a glass tube, it gives off watery vapor, and in the flame of a lamp decrepitates. It does not melt before the blowpipe on charcoal; with borax it gives a bead, yellow while hot, colorless when cold. It is decomposed by acids. By analysis it proves to be a silicate of the oxide of the new metal, containing 71.247 per cent. of the oxide, 17.695 of silicic acid, 69 of water, and 4.042 of carbonate of lime. The metal is obtained as a black powder by treating the oxide with potassium. It takes fire in a flame, burns with a reddish light, and is converted into the red oxide. The specific gravity is nearly 7.35.

DONATELLO, or properly Donato di Betto di Bardi, one of the revivers of sculpture in Italy, born in Florence in 1383, died in 1466. He was of the family of Donato, which has counted many learned men among its members, and which after the middle of the 16th century gave several doges to the republic of Venice. He was educated under the care of a rich relative, and found in Cosmo de' Medici, the chief of the Florentine republic, a patron able to perceive and to reward his merits. The "St. Peter" and "St. Mark" which adorn the church of St. Michael in his native city were his first 2 great works. He afterward studied in Rome, and occupied himself particularly with repairing the injuries that had been wrought upon the ancient productions of sculpture. The natural tendency of his mind led him toward an imitation of the antique; yet his manner was bold and independent, and his success was such that his contemporaries thought that nothing was wanting to the proportion of form and vivacity of expression which he gave to marble. The sudden progress which the art of sculpture made under his labors challenged the utmost exertions, even if it did not excite the jealousy, of the first painters of the age. He particularly excelled in works in *rilievo*, among which were his "Nativity and Burial of Christ," and the "Assumption of the Virgin." His most celebrated statues, the group of "Judith and Holofernes," executed in bronze for the community of Florence, that of "St. George," the finest ornament of the church of St. Michael, and his "Zuccone," his own favorite piece, representing an old man in the costume of a senator, all yet remain, and have met with the uniform approbation of succeeding times. Donatello was buried according to his desire in the church of San Lorenzo, by the side of his friend Cosmo de' Medici. His liberality and disinterestedness were such, that he kept his money in an open basket hung on the wall of his room for the free use of his workmen. Nothing irritated him more than to see his works sold to persons unable to appreciate them; he sometimes broke a finished piece to fragments to save it from such a destiny.

DONATISTS, the name given to a schismatical and afterward heretical party in the African church. Connected with this party were several persons named Donatus, 2 of whom, Donatus of Casæ Nigræ, in Numidia, and Donatus of Carthage, were eminent. From one, or perhaps both of these men, the schism received its designation. Its first outbreak was in the opposition of the Numidian bishops to the confirmation of Cæcilianus as successor to Mensurius (A. D. 311) in the episcopal see of Carthage. It was alleged as an offence both of Mensurius and Cæcilianus that they had received back into the church, and admitted to full fellowship, some of those *traditores* whom the discipline of the church had strictly condemned. *Traditores* was the designation of a class of Christians who, in the recent persecution under Diocletian, had obeyed the imperial order, and had given up their Bibles and their sacred vessels to be destroyed by the pagan officers. A rich lady of Carthage, whose excessive reverence for relics Cæcilianus had rebuked, lent to the discontented the weight of her influence. The Numidian priests, complaining that they had not been summoned to the election of the bishop, as they should have been, met in council at Carthage, and sent for Cæcilianus to appear before them and explain his conduct; and on his failure to do so declared his deposition, on the double ground of heresy in the matter of the *traditores* and of illegality in the election. Majorinus, the domestic chaplain of the noble lady Lucilla, above mentioned, was chosen as bishop in the place of Cæcilianus. An appeal was made by Cæcilianus to Constantine, and the emperor referred the matter to a council, which was held at Rome in 313, and which, under the direction of Miltiades, bishop of Rome, declared Cæcilianus innocent, and reinstated him in his bishopric, while it regretted, rather than condemned, the acts of the schismatic party.

The Donatists did not obey this sentence, and a new and more imposing council held at Arles in 314 was equally barren of result, except to inflame partisan wrath. Appealing to Constantine, the Donatists found no help; the emperor favored the moderate party, and consented to the decision of the council. The death of Majorinus in 316 did not open the way to a reconciliation. The Numidian party chose in his place another Donatus, a man of large scholarship, pure character, singular benevolence, and incorruptible firmness. The new bishop at once devoted himself to the organization of the schism. He encouraged his followers to maintain the position they had taken. He counselled them to a more austere morality, and a more strict observance of the Christian ritual. They were fined, imprisoned, expelled from the churches, driven to the mountains; but they constantly rallied, returned, and drove out their rivals. In a great council at Carthage of 270 bishops, they affirmed that theirs was the only Catholic church, and that the churches of Europe were schismatic. Constantine at last, weary of the fruitless effort to silence them, ceased to molest them. The episcopal life of Donatus of Carthage seems to have continued, in varying fortunes, for more than 30 years, in which time the Donatist party had grown to be the dominant church of Africa, numbering more than 300 bishops. In the towns and cities, the members of the sect confined themselves mostly to the milder measures of preaching and writing to defend their cause. But about the year 347 a fanatical party appeared in the mountains, who delivered themselves to the wildest excesses, going about the country plundering, burning, even murdering, and courting martyrdom as a joy and a privilege. These Circumcelliones (for such was the designation of this party) resorted often to suicide as a substitute for legitimate martyrdom, and sometimes compelled strangers, whom they met on the roads, to murder them. These excesses found, if not a defender, at least an apologist, in Donatus, who would not lend himself as an instrument of the emperor's vengeance, contending that it was an affair of the church and not of the empire. Paul and Macarius, the envoys of the emperor, were forced to employ the army to disperse and destroy these ignorant fanatics. These violent measures only strengthened the hatred of the Donatists against the Catholics. The sympathy of the civil power was drawn to them, and not bishops only, but governors and judges, took the side of the schism. The reign of Julian was still more favorable to their cause. They dared to defend the outrages committed in the name of a pure religion. Parmenian, successor of Donatus in Carthage, wrote an apology for the sect. This was answered by Optatus, and afterward by Augustine, to whom, more than any other writer, the downfall of the schism is due. Half a century longer the contest between the 2 parties continued to rage, the issue gradually turning against the schism. In the beginning of the 5th century the emperor Honorius attempted a new persecution; and in 411, in a conference between the Catholics and Donatists at Carthage, the latter were condemned and severe laws passed against them. A few bishops of the Donatist party succumbed and were received into the church; but most of them resisted, and were driven and hunted into the interior region, and forced to hide themselves in the mountains and the desert. A few ineffectual attempts at union were made by the party under succeeding emperors, but before the close of the century the sect had become virtually extinct, existing only in fragments in parts remote from the coast. The Vandal invasion overwhelmed at once Catholic and heretic, and in its great ruin made the church forget all minor strifes.—The heresy of the Donatists was twofold, a heresy of theory and of practice. The theoretical heresy consisted in asserting that the character of the minister influenced his ministration, and that the sacraments from the hand of one not properly ordained for the work were of no value, whatever the spirit of the recipient. The practical heresy consisted in rebaptizing those who came from the Catholic churches into their communion, and consecrating anew the sacred edifices which they took from their rivals. The ground of their condemnation was that they were exclusive and bigoted, and that they treated the Catholics as no better than Jews or idolaters. Donatus and others of his party, indeed, were accused of denying the Trinity; but from this charge they are expressly absolved by Augustine, who shows that they differ from the Arian party in recognizing but one divine substance. The Arians sought in vain to unite the Donatists to their party.—An account of the Donatists may be found in the works of St. Optatus; in Tillemont, vol. vi.; in the "Dissertation" of Collina (Bologna, 1758); in Ballerini's history; in De Potter's "History of Christian Churches," vol. ii. (Paris, 1836); in Villemain's *Tableau de l'éloquence Chrétienne au V^e^ siècle* (new edition, 1854); and in Ribbeck's *Donatus und Augustinus* (Elberfeld, 1857).

DONCASTER, a parish and handsome market town of England, in the county of York, West Riding; pop. in 1851, 12,052. The town is pleasantly situated on the river Don, here navigable and crossed by 2 stone bridges. It is in the centre of a populous and highly cultivated district, but is indebted for its celebrity to its horse races, which have an almost unrivalled reputation in the sporting world. They were established in 1703, and the list of winners since that time includes the best horses that have been bred in England. The famous St. Leger stakes were founded in 1776. The race course is 2 miles in length, and one of the finest in the kingdom. The expense of improving it since 1777 is said to have amounted to £20,000. The races are held annually in the 3d week of September, and continue for 5 days. Doncaster is the *Danum* mentioned in the itinerary of Antoninus; hence its Saxon name *Dona Castre*, and its pres-

ent name. It was, prior to the reformation, the seat of several convents of Carmelites, and white, black, and gray friars. It is the birthplace of Richard Plantagenet, of Conisburgh, and Sir Martin Frobisher. A new parish church finished in 1858, at a cost of £52,000, is said to be the finest in England. Roman antiquities are frequently found in the city and vicinity.

DONEGAL, a maritime county of Ireland, bounded on the N. and W. by the Atlantic, on the E. by the counties of Londonderry, Tyrone, and Fermanagh, and on the S. by the counties of Fermanagh and Leitrim, and by Donegal bay; area, 1,865 sq. m.; pop. in 1851, 255,160. The shores are deeply indented by bays, the principal of which are Sheephaven, Gliddore, Gnybarra, and Lochrus bays. There are numerous islands off the coast, and several lakes within the limits of the county. The general aspect of the surface is mountainous. Nearly ⅔ of the land consist of bogs or sterile hills, incapable of cultivation. The chief rivers are the Swilly and the Leenan, and the principal towns Ballyshannon, Letterkenny, Ramelton, Donegal, and Killybegs. Oats, barley, flax, and potatoes are the staple agricultural productions. The total extent of land under crops comprised 232,353 acres in 1854, and 228,683 in 1855. The fishery districts employ about 2,000 vessels and 9,000 hands. The linen manufacture is actively carried on in several parts of the county, and there are also many corn mills, but the export trade is chiefly carried on through the port of Londonderry. Capital, Donegal.

DONETZ, or Donets, a river of Russia, principal affluent of the Don, about 400 m. long. It rises in the government of Koorsk, pursues a S. E. course through the government of Kharkhov and the country of the Don Cossacks, and joins the Don on the right. Its banks are generally fertile, and its channel is wide and deep. The Oskol, the Aidar, the Kalitva, and some smaller branches join it on the N.; and it is navigable from its mouth to Zmiev.

DONGOLA, a province of upper Nubia, on the Nile, between lat. 18° and 19° 30′ N.; length, about 150 m.; breadth equal only to the strip of alluvial land lying between the river and the desert, and varying from 2 to 6 m. It contains the towns of New Dongola, or Maraka, Dongola Agous, or Old Dongola, Debbah, and Korti. It was a Christian country until the 14th century, was ravaged and subdued by the Sheygia Arabs in the 18th century, and is now subject to the pasha of Egypt, and governed by a bey who resides at New Dongola. The inhabitants are black, but not negroes, and resemble the people of lower Nubia. The productions are indigo, durra, barley, beans, sheep, goats, cattle, and horses, which rival in beauty and surpass in size the best breeds of Arabia.

DONIPHAN, a N. E. co. of Kansas, bounded N. by Nebraska, and separated from Missouri on the E. by the Missouri river; area, about 312 sq. m.; aggregate pop. of 12 principal towns in 1859, 4,700. It is well watered by the Missouri and several small streams, is well timbered with cottonwood, elm, sycamore, &c., abounds with building stone, and is the 3d co. of the territory in wealth and population. The surface consists in part of rolling prairies, somewhat broken near the streams, but gently undulating in the interior. The river bottoms have a rich soil, generally timbered. The old overland route to California crosses the county, and the Hannibal and St. Joseph railroad terminates at St. Joseph, Mo., opposite Elwood. Five newspapers are published in the county. Capital, Troy.

DONIZETTI, Gaetano, an Italian composer, born in Bergamo, Sept. 25, 1797, died there, April 8, 1848. He was originally destined for the law, but showing an unusual taste for art, he was placed at the musical institute of Bergamo, then under the direction of Simon Mayer, and subsequently studied at Bologna, under Pilotti and Mattei. At the age of 20 he had composed some short pieces of religious and instrumental music, evincing the severity of his studies and the direction of his taste, when the brilliant career of Rossini captivated him, and he determined to write for the stage. His father opposed his plans, and in a fit of pique Donizetti entered the Austrian military service, and while in garrison with his regiment in Venice produced in 1818 his first opera, *Enrico di Borgogna*. Several other works followed, and in 1822 his *Zoraïde di Granata*, produced in Rome, procured him his discharge from the army, with which he had become heartily disgusted. His works now began to succeed each other with great rapidity, and in 1827 he accepted an engagement with Barbaja, the director of the theatres at Naples, to write 4 operas a year, 2 serious and 2 buffo, for 4 years. In 1830, when his *Anna Bolena* was produced at Milan, he had written 31 operas, nearly all of which were successful, but short-lived. At this time Bellini appeared, and Donizetti, who had hitherto been a professed imitator of Rossini, modified his style by borrowing somewhat of the tenderness and pathos of his young contemporary. He even went to Paris in 1835 to compete with him, but without success, his *Marino Faliero* being eclipsed by Bellini's *Puritani*. He returned at once to Naples, and in 6 weeks composed his *Lucia di Lammermoor*, the success of which repaid him for his disappointment. It was produced throughout Europe and even in Paris in the succeeding year with a success which seems undiminished at the present day. In 1840 he returned to Paris, and immediately brought out *Les martyrs*, *La favorita*, and *La fille du régiment*, the last 2 of which are still universal favorites. The reputation acquired by these and other works procured him the appointment of professor of counterpoint at the royal college of music in Naples, and of chapelmaster and composer to the court of Vienna. His last operas were *Don Sébastien* (produced at Paris in 1844, and which he wrote out in 2 months, remarking at the close of his labors: "*Don Sébastien* will be the death of me"), and *Catarina Cornaro*, produced at Naples in

1844. Soon afterward a mental affection, the result of early habits of dissipation and of excessive application, compelled him to abstain from work of every description, and for the last few years of his life he was the inmate of a lunatic asylum. In addition to the works specified, he composed *Lucrezia Borgia* (Milan, 1833), *Linda di Chamounix* (Vienna, 1842), *Don Pasquale* (Paris, 1843), and *Maria di Rohan* (Vienna, 1843), all of which are constantly performed in Europe and America. Donizetti produced upward of 60 operas in the course of his life, most of which, however, in consequence of the haste and carelessness with which he wrote, have sunk into obscurity. In the fulness and variety of his melodies, and in his appreciation of dramatic fitness in single or concerted scenes, he stands almost unrivalled, and some of his works are likely to long retain their hold upon popular favor. His facility was such that he is known to have written out the score of an opera in 2 days. Toward the close of his life his operas showed a marked improvement.—His brother GIUSEPPE officiated for many years as director of the military music of the sultan, and died in Constantinople in Feb. 1856.

DONNE, JOHN, an English poet and theologian, born in London in 1573, died in 1631. He was of a Roman Catholic family, studied both at Oxford and Cambridge, and though designed by his parents for the law, relinquished it in his 19th year for theology, which was the chief interest and passion of the time. He abandoned the Roman Catholic church for the Anglican, and travelled and tarried some time in Spain and Italy. On his return to England he was appointed secretary to Sir Thomas Egerton, keeper of the great seal, which post he held for 5 years; but having secretly married Anne, the daughter of Sir George More, and the niece of Lady Egerton, he was dismissed from his situation and for a time imprisoned in the tower. He was reconciled to Sir George by the mediation of Sir Francis Wooley. He afterward accompanied Sir Robert Drury to Paris, and returning to England was presented to James I., by whose command he wrote the "Pseudo-Martyr" to prove that Roman Catholics might conscientiously take the oath of allegiance. At the age of 42 he entered into orders, and having at once distinguished himself as a preacher he was made by the king his chaplain in ordinary and dean of St. Paul's, and received from the university of Cambridge the degree of doctor of divinity. His failing health obliged him to desist from preaching, but a calumnious whisper having reached him that his sickness was feigned because he chose to be idle, he ascended the pulpit and preached what his biographer has called his own funeral sermon, which was afterward printed with the significant title of "Death's Duel." He died soon after, admired and almost reverenced for his holiness. He left sermons and devotional and controversial works, but he is best known as a poet. His poems consist of satires, elegies, epigrams, and religious and complimentary verses. His subtle and vivid imagination, and his great simplicity and tenderness of character, are manifest amid his vast learning and the abounding vicious conceits of his style. He was the first of the series of English poets characterized by Dr. Johnson as metaphysical. His rugged numbers and laborious faults made him little esteemed during the last century, but lately the scattered gems of poetry and melody in his books have recalled something of his first reputation, and his works have been republished under the editorial care of the Rev. Henry Alford (6 vols. 8vo., London, 1839). His life was written by a contemporary and very congenial spirit, the angler Izaak Walton, whose admiration of him was unbounded.

DONNYBROOK, or ST. MARY'S OF DONNYBROOK, a parish and village of Ireland, co. of Dublin. The parish contains the villages of Irishtown, Donnybrook, Merrion, Ringsend, and Sandymount; area, 1,689 acres; pop. in 1851, 11,177.—The village, 2 miles S. E. of Dublin, of which it is a suburb, is situated on the Dodder, here crossed by a handsome bridge, and contains a fine church, several chapels, a Magdalen asylum, a dispensary, a lunatic asylum, classical and other schools, a hat manufactory, and a number of mills. It is celebrated for its fair, granted by King John, and formerly held during 15 days from Aug. 26, but now lasting only a week, and being merely a pleasure fair. It was originally for the sale of horses and black cattle, but became notorious by frequent scenes of riot, bloodshed, and debauchery. The magistrates have succeeded of late years in repressing such disorders.

DONOSO CORTES, JUAN FRANCISCO MARIA DE LA SALUD, marquis de Valdegamas, a Spanish writer and statesman, born in Valle de la Sarena, in Estremadura, May 6, 1809, died in Paris, May 3, 1853. At the age of 12 he had finished his classical studies, and entered upon a course of law at the university of Salamanca. He was entirely prepared to receive his degree at the age of 16, but the rules not permitting it until the age of 25, he went to Seville, and employed the intervening years in the study of philosophy, history, and literature. He commenced his public career as professor in the college of Caceres. During the divisions which took place in Spain in 1832, with regard to the right of succession to the throne, Donoso presented a memoir to Ferdinand VII., in which he pleaded the liberal cause with great eloquence. The king rewarded him by a distinguished place in the ministry of justice. After the death of Ferdinand he warmly defended the cause of Queen Isabel and her mother. He was elected to the cortes, and afterward appointed secretary to the ministerial council. Differing essentially from Mendizabal, who was at its head, he resigned his post, and devoted himself zealously to the tribune and the press. Defending a middle ground between absolute power and revolutionary government, he was at this period one of the foremost representatives of liberalism. He was for some

time the editor of the *Revista*, and a leading contributor to the *Piloto*, a newspaper founded by himself. At the same time he gave at Madrid a course of lectures on political rights. During the dictatorship of Espartero, Donoso defended the interests of Maria Christina. In this contest he was vanquished, and shared the exile of the queen mother to France as her private secretary, and also accompanied her on her return to Spain in 1843. He was afterward appointed secretary to Queen Isabel, and director of her studies; he was reëstablished as member of the cortes, and the post of minister was offered him, but he declined it. Shortly afterward he was appointed minister plenipotentiary to the court of Berlin. The death of a brother made a great impression on Donoso, and from that time his writings acquired a strong religious tendency. In his speech in the cortes, Jan. 4, 1849, he renounced all liberal ideas, which he designated as sterile and disastrous to human society, whose peace had been disturbed by them for 3 centuries. This discourse made a great sensation in France and Spain. A work of his in French, entitled *Essai sur le Catholicisme, le libéralisme, et le socialisme* (1 vol., Paris, 1851), maintained that theology is the proper basis of politics. It was attacked by both radicals and Gallicans. Its author answered by sending it to Rome, condemning in anticipation whatever Rome should condemn; but hitherto Rome has not spoken, and the congregation of the Index has not interdicted the book. Among his principal writings may be mentioned *Consideracions sobre la diplomacia, y su influencia en el estado politico y social de Europa* (Madrid, 1834); *La ley electoral, considerada en su base y en su relacion con il espiritu de nuestras instituciones* (Madrid, 1835); and a collection of his speeches and early writings (Madrid, 1849–'50). The 3d and last volume of a complete French edition of his works appeared in Paris in 1859.

DONOVAN, Edward, an English popular writer upon subjects of natural history, died Feb. 1, 1837. His first publication was a "Natural History of British Insects" (16 vols. royal 8vo., London, 1792–1813); of a similar character to which were his "Natural History of British Birds" (10 vols. royal 8vo., 1794–1818); "Fishes" (5 vols. royal 8vo., 1802–'8); "Shells" (5 vols. royal 8vo., 1803–'4); and "Quadrupeds" (3 vols. royal 8vo., 1820). In 1798 he published in 4to. an "Epitome of the Natural History of the Insects of China," which was followed by works on the insects of India (1800), and of islands in the Indian and South Pacific oceans (1805). He also published a little book of instructions concerning the collection and preservation of subjects of natural history. His later works were a narrative of "Excursions through South Wales and Monmouthshire" (2 vols. 8vo., London, 1805); a periodical publication, entitled the "Naturalist's Repository;" and an "Essay on the Minute Parts of Plants." The works of Mr. Donovan were not designed for the instruction of men of science, but they have been serviceable in creating a general interest in the subjects of which he wrote.

DOOLY, a S. W. co. of Ga., with a level surface, well watered by many small creeks, bounded W. by Flint river; area, 530 sq. m.; pop. in 1852, 9,321, of whom 3,483 were slaves. Pine forests occupy much of the land, but the soil is fertile, and the cultivated tracts produce excellent crops of grain, cotton, sugar cane, and potatoes. In 1850 the county yielded 5,962 bales of cotton, 289,378 bushels of Indian corn, and 94,645 of sweet potatoes. There were 225 pupils in the public schools. Value of real estate in 1856, $1,205,575. The county, organized in 1821, was named in honor of Col. John Dooly, a revolutionary officer. Capital, Vienna.

DOOLY, John Mitchell, an American lawyer, born in Lincoln co., Ga., about 1772, died May 26, 1827. His father, Col. John Dooly, emigrated from North Carolina at the beginning of the American revolution, and did good service throughout that struggle. In 1802 John M. Dooly was appointed solicitor-general of the western circuit, to fill a vacancy, and in 1804 he was elected to the same office by the legislature. He was elected judge of the western circuit in 1816; and in 1822 was elected the first judge of the newly made northern circuit, to which office he was reëlected in 1825. Though a man of vigorous intellect and one of the most successful lawyers of his day, he is more widely known as a wit and humorist than in any other capacity, and probably a greater number of anecdotes are related of him than of any other man who ever lived in Georgia.

DOON, a lake and river of Scotland, in Ayrshire. Loch Doon is about 8 m. in length, and at no place exceeds ¾ of a mile in breadth. It is enclosed by the Star mountains of Kirkcudbright, from the base of which the river Doon takes its rise, while from their opposite side the river Dee starts. The lake abounds in trout, and has an islet on which stands an old castle, reputed to have once been the residence of Edward, brother of Robert Bruce. The river Doon issues from the lake, and after pouring impetuously for about a mile through a wild and rocky ravine, called Ness Glen, passes into gentle and sylvan scenery, and after a N. W. course of 16 m. falls into the frith of Clyde, 2 m. S. of Ayr. About a mile from the sea, close by the side of the river, stands a monument to Burns, who sang of the "banks and braes o' bonny Doon."

DOOR (Sax. *dor*), a movable shutter, usually of framed timber, placed upon hinges, or sliding in grooves, and employed for closing an opening termed a doorway. Doors are of various materials, sizes, patterns, and forms. Those used by the ancient Egyptians in their domestic architecture were of wood, usually native, though often stained to resemble rare foreign woods. In the mansions of the wealthier classes it was customary to build porches or porticos in front of the outer doors; these were about 12 or 15 feet in height, slightly exceeding that of

the cornices of the doors, and the columns supporting them were often decked with banners or ribbons. Above the door was sometimes inscribed a sentence, as "The good house," or the name of the king under whom the owner had perhaps held office. The doors were either of one or two leaves, turning on pins of metal, and secured within by a bar or bolts; the folding doors had bolts in the centre, sometimes above as well as below, and a bar was placed across from one wall to the other. According to Hamilton, no vestiges of doors have been discovered in the temples of Egypt, though in some cases holes have been observed in the stone lintels and floors, in which they might have turned, as well as those for the bolts and bars, and the recess for receiving the opened leaves; it seems highly probable that doors were employed, and perhaps of bronze, as the Egyptians possessed the art of working in metals much earlier than the time of Herodotus, who describes the door of the temple of Belus at Babylon as made of metal, which is supposed to have been bronze. Wood was used for constructing the doors of Solomon's temple: "And for the entering of the oracle he made doors of olive tree; the lintel and side posts were a fifth part of the wall. The two doors also were of olive tree; and he carved upon them carvings of cherubims and palm trees and open flowers, and overlaid them with gold, and spread gold upon the cherubims and upon the palm trees." (1 Kings, vi. 31, 32.) The doors of the Egyptians, and of the Romans, opened inward in all cases, and the latter were expressly forbidden to make a street door open outward without a special permission; the custom of the Greeks was exactly the reverse, and they were consequently obliged to strike on the inside of the street door before they opened it, in order to warn persons passing by. The Roman and Grecian doors were often elaborately ornamented with ivory and precious metals. Those of the middle ages were frequently constructed with skill, and embellished with ornamented handles, knockers, locks, and tracery; but the existing examples are not numerous, on account of their fragility as compared with the materials of the buildings to which they belonged.—The proportions of doors vary according to the size and intention of the building; as a general rule, for large doors the breadth may be $\frac{1}{2}$ the height, and in small doors $\frac{2}{3}$. In buildings of any magnitude, the principal entrance should be in the centre, both as producing greater symmetry of appearance, and as communicating more readily with all portions of the interior; in the principal rooms the door should be at least 2 feet from the return of the wall, to admit of furniture being placed in the corner if desired.

DOOR, a N. E. co. of Wis., consisting of a narrow peninsula between Green bay and Lake Michigan; area, 625 sq. m.; pop. in 1855, 739. It was formed in 1851 out of a portion of Brown county. Value of real estate in 1855, $120,000. Capital, Gibraltar, or Bailey's Harbor.

DOOSTEE, Dustee, Dusee, Doost, Doust, or Dust, a river of Beloochistan, the position of whose source is unknown. Flowing from the interior, it traverses the province of Mekran, and enters the Indian ocean in lat. 25° 15′ N., long. 61° 50′ E. Its total course under various names is supposed to be about 1,000 m., but it is generally shallow, and is of little commercial importance.

DORAT, Claude Joseph, a French poet, born in Paris, Dec. 31, 1734, died April 29, 1780. He was intended for the bar, but at the age of 20 commenced a literary career by producing an unsuccessful tragedy. He then turned his attention to light poems, tales, and sketches, which he threw off with great rapidity, and by which he acquired considerable reputation, although the extravagant profuseness with which he illustrated his most trifling works involved him in pecuniary ruin. He wrote several more pieces for the stage, which exposed him to ridicule from contemporary wits. He failed to obtain admission to the academy, and but for the charity of Beaumarchais and Mme. de Beauharnais he might have died of starvation. He expired in the act of correcting a proof sheet. His works fill 20 vols., but are not highly esteemed. His tales are humorous but indecent.

DORCHESTER, a S. E. co. of Md., bordering on Delaware and on Chesapeake bay, bounded N. and N. W. by Choptank river, and S. E. by the Nanticoke, both of which are here navigable; area, 640 sq. m.; pop. in 1850, 18,887, of whom 4,282 were slaves. It has a level and partly marshy surface, with a soil sandy in some places and clayey in others. The productions in 1850 were 55,000 bushels of Indian corn, 137,470 of wheat, 8,496 of oats, and 84,816 lbs. of butter. There were 2 coach factories, 1 hat factory, 2 newspaper offices, 26 churches, and 798 pupils attending public schools. Organized in 1669. Capital, Cambridge.

DORCHESTER, a township of Norfolk co., Mass., on Dorchester bay, an arm of Boston harbor, contiguous to South Boston; pop. in 1855, 8,340. It is a fertile, highly cultivated, and diversified part of the county, laid out in numerous villages, and a favorite residence for the business men of Boston. It communicates with that metropolis by the Old Colony and the New York and Boston central railroads, and by a horse railroad. In 1855 it contained 1 iron furnace, 1 forge, 1 manufactory of britannia ware, 1 of starch, 1 of cordage, 3 of railroad cars, carriages, &c., 2 of soap and candles, 3 of tin ware, 1 of refrigerators, 3 of chocolate, 3 paper mills, and 1 gas manufactory. In 1859 it had 2 banks, 1 insurance office, 2 libraries, 11 churches, an industrial school for girls, a literary association, and a historical and antiquarian society in Dorchester village. The township contains 4 post offices, viz.: Dorchester, Neponset, Harrison Square, and Mattapan. It was first settled by a party of English Puritans, headed by the Rev. John White of Dorchester, England, who landed at Nantasket, June 11, 1630, and

established themselves within the limits of the present township on the 17th of the same month. They soon erected a church, but no trace of it now remains, and no one can point out where it stood. The first water mill in America was built here in 1633, and Dorchester has the honor of having originated about the same time the New England cod fishery. In 1804 the N. E. part of Dorchester was annexed to the capital under the name of South Boston. Washington village was incorporated with Boston in May, 1855, and that part of Dorchester called Squantum was added to the town of Quincy at the same time. Edward Everett was born in this town.

DORCHESTER, a decayed village at the head of Ashley river, Colleton district, S. C., 18 m. N. N. W. from Charleston. It was distinguished during the revolutionary war as a military post, both of the Americans and the British, and as the theatre of a variety of interesting incidents. It was settled originally in 1696 by the members of a Congregational church from Dorchester, Mass., under the spiritual charge of the Rev. Joseph Lord, and in its palmy days held a permanent population of 300 or 400 inhabitants. By an act of the assembly in 1723, and while it was yet a frontier post, it was established as a "fair and public market," and was therefore a place of gathering for the people of the borders, white as well as red. It was garrisoned by the Americans and British during the revolution, as each party had possession, and an old fortress still remains, one of the few evidences of the old settlement. Several brisk actions took place in and about the precinct.

DORCHESTER, a municipal and parliamentary borough, market town, and the capital of Dorsetshire, England, near the river Frome, 141 m. S. W. from London by the London and Southwestern railway; pop. in 1851, 6,394. It contains 3 churches, several schools and charitable institutions, a theatre, large cavalry barracks, and a county museum. It has considerable trade in beer, butter, sheep, and lambs. It was fortified by the Romans, who surrounded it with a wall. Athelstan made it the seat of 2 mints, and during the civil war it witnessed many severe battles. In the vicinity are the remains of a Roman ampitheatre and camp, and of a British station called Maiden castle.

DORCHESTER, a river port, and the capital of Westmoreland co., New Brunswick, on the left bank of the Petticodiac river, a little above its mouth in Shepody bay. A valuable, brilliant black inflammable mineral, containing a large quantity of gas of high illuminating power, is found in the vicinity. It is called by some jet coal, and by others is thought to be pure asphaltum.

DORDOGNE, a S. W. department of France, composed of portions of the ancient provinces of Guienne, Agenois, Périgord, Limousin, and Angoumois; area, 3,492 sq. m.; pop. in 1856, 504,651. It is divided into 5 arrondissements, 47 cantons, and 585 communes. Capital, Périgueux. A large part of the land is occupied by marshes; nearly $\frac{2}{3}$ are considered unfit for cultivation, but the department is very rich in minerals. Iron, copper, lead, coal, manganese, lithographic stones, and marble are found in large quantities. The surface is hilly, and covered in many places with extensive forests. Chestnuts are abundant, and are cultivated to a considerable extent. Game is plentiful, but cattle, owing to the poorness of the pasture lands, are raised in very small numbers. Red and white wines of good quality are produced; the crops of grain are fair, and the truffles of Dordogne are esteemed the best in France. The principal manufactures are iron, paper, brandy, and liqueurs. The largest rivers are the Dordogne (from which the department is named) and the Vezère, both of which are navigable.

DORÉ, Paul Gustave, a French artist, born in Strasbourg in Jan. 1833. He received his education at the *lycée Charlemagne* in Paris, and since 1848 has been constantly before the public as a painter of landscape and *genre*, and as a designer for illustrated editions of Balzac, Rabelais, and other authors. His series illustrating the legend of the "Wandering Jew" (1856) possesses a remarkable grotesqueness and power. The vividness of his imagination frequently, however, leads him into exaggeration.

DORIA, a family of Genoa, celebrated in history for the great number of distinguished men which it has produced since the 12th century. The influence which this family and that of the Fieschi, the Grimaldi, and the Spinolas exerted upon the destinies of Genoa was so powerful, that the 4 families were called *Magnæ quatuor Prosapiæ*, the Dorias and the Spinolas siding with the Ghibelline party, and the other two with the Guelphs. As early as the 12th century many high offices in the state were held by members of the Doria family, and 4 of them were distinguished admirals before the 14th century. Their fame, however, was eclipsed by Andrea Doria, the celebrated ruler of Genoa, and admiral, born in Oneglia, Nov. 30, 1468, died in Genoa, Nov. 25, 1560. In early life he was successively employed in the service of Pope Innocent VIII., of the duke of Urbino, of Ferdinand and Alfonso II. of Naples; and having passed some time in the Holy Land, where he became a member of the order of St. John, he distinguished himself after his return to Italy by his exploits against Gonsalvo de Cordova and the Corsicans. At the beginning of the 16th century he was placed at the head of the navy of Genoa, and soon displayed the remarkable naval abilities for which he was distinguished, especially by clearing the waters of Genoa of pirates and corsairs. When the political troubles in Genoa induced him to remove to Monaco, he showed as much public zeal in his retirement as he had while in power, and fitted out at his own expense 12 galleys which he had taken from the corsairs. When the war between Francis I. and Charles V. broke out, he accepted the command of the French galleys. After defeating the imperial

fleet at Marseilles in 1524, and rendering various other signal services to the cause of France, he took umbrage at the attempt of Francis to injure Genoa, by setting up a rival for her in fortifying the city of Savona, and, displeased at the same time with the personal treatment to which he was subjected, he left the French service to join that of Charles V., with whom he stipulated for the freedom of Genoa as the price of his services. By going over to the Spanish Austrian party he paralyzed the progress of the French arms in Italy, and became the deliverer of his country by expelling the French from Genoa. This happened in 1528. After the conclusion of peace on Aug. 5 of the following year, Doria was invested with the supreme power of Genoa, although he declined to accept the official dignity of doge, as this would have prevented him from remaining, as he wished, attached to the service of Charles V. The senate conferred upon him the name of "the father of peace," and ordered a statue to be erected to him and a palace to be placed at his disposal. He inaugurated a new form of government, making the office of doge biennial instead of for life, terminated the fatal dissensions between the Adorni and Fregosi, and recalled the banished members of the Genoese aristocracy, without however granting them on their return any privileges over the other classes of society. While restoring order and governing the affairs of the republic, he continued to render himself useful to Charles V., who appointed him commander-in-chief of his navy, invested him with the order of the golden fleece and the principality of Melfi, and raised the number of his galleys to 22. The favors of the emperor were fully repaid by Doria's achievements in the interests of the empire. In 1532 he took from the Turks the towns of Coron and Patras in Greece, and ravaged the whole coast of that country, compelling the sultan by this diversion to evacuate Austria and Hungary. The conquest of Tunis in 1535 was mainly due to his skill and bravery. In 1536 he took part in the invasion of Provence, captured Toulon, and carried the war to the gulf of Lyons. After the defeat of the imperial army by the French, he accompanied the emperor to Barcelona; and when, under the auspices of Pope Paul III., a truce was concluded between the 2 parties, the interview between Charles V. and Francis I. took place on board of one of Doria's galleys, this opportunity serving at the same time to effect a reconciliation between himself and his former master, the king of France. In Doria's subsequent career in the service of Charles his good fortune seems to have abandoned him. In 1539 he neglected to avail himself of his superior force for the purpose of defeating at Prevesa the Turkish fleet under Khair-ed-Deen of Algiers, brother of the famous Barbarossa; and in 1541, during the fatal expedition of Charles to Algiers, he lost 11 of his galleys. On his return to Genoa he applied himself for the rest of his life to the administration of the affairs of the republic, which however was disturbed by the revolution instigated by the Fieschi family. In the first outbreak of 1547 his nephew Gianettino Doria lost his life (which caused Andrea to punish the conspirators with great severity), and Fiesco himself was drowned accidentally. Doria's death, at the age of 92, was deplored as a national calamity, and as the news of it spread over Genoa, the people exclaimed: "Andrea Doria is dead; the republic is left without a champion." The statue erected to him at Genoa bears an inscription characterizing him as "the father of his country."

DORIANS, the name by which one of the 4 chief branches of the Hellenes, the descendants of Dorus, son of Hellen, were distinguished in the history of ancient Greece. In the remotest period they appear on the classical ground of fabulous antiquity, between Mount Olympus and Ossa; then, by turns conquering and conquered, in Macedon, on the island of Crete, in Doris, where they founded the Tetrapolis, and in the Peloponnesus, which they entered under the returning Heraclidæ, and where they became masters of Sparta, Argos, and Messenia. They distinguished themselves from other Hellenic tribes, particularly from the Ionians, by a character of dignified solidity, of rigid and often rough gravity. This manifested itself not only in their manners, laws, and institutions, so much in contrast with those of the milder Ionians, but also in their dialect, broad and rough, but strong and solemn, and therefore well suited to sacred hymns and choruses; in the light hunting dress of their women, in the strong and unadorned Doric column, in the warlike sounds of their music, and even in the spirit of the Pythagorean philosophy; while every thing Ionian was marked by a character of softness, elegance, and taste. Colonies of the Dorians flourished in Italy, Sicily, and Asia Minor. The best authority on the Dorians is K. O. Müller, *Die Dorier* (2d ed. 3 vols., Breslau, 1844).

DÖRING, Theodor, a German actor, born in Warsaw in 1803, since 1840 connected with the royal theatre of Berlin, celebrated for his admirable personations of Mephistopheles, Shylock, Richelieu, and similar characters.

DORIS, now belonging to the eparchy of Phocis, in N. Greece, a small mountainous region, watered by the Mavropotamo, anciently one of the smallest divisions of Hellas, inhabited by the Dorians, and bounded by Thessaly, Phocis, Locris, and Ætolia. Of its 4 confederate cities, the so-called Tetrapolis, built at the foot of Mount Œta, none was adorned by great names or events of Grecian history. They were soon destroyed by hostile neighbors, and were in ruins in the time of the Romans.—Doris in Asia Minor, a part of the coast of Caria, settled by a colony of Dorians, contained a confederacy of 6 cities, which, though dependent at every period of history on some larger state, had, on the promontory of Triopion, a place of national assembly, where festivals and games were celebrated, and common affairs discussed.

DORKING, or Darking, a market town and parish of Surrey, England, situated in a beautiful valley on the left bank of the Mole, 21 m. S. W. of London; pop. in 1851, 5,996. It is noted for its romantic scenery. The Dorking fowls, celebrated for their excellent qualities, and in such demand for the London market, are supposed to have been introduced here by the Romans. They are usually white or of a partridge color, and have 5 claws on each foot. The neighboring country contains many beautiful residences, among which are Deepdene, the seat of the late Thomas Hope, and the Rookery, where Malthus was born.

DORMOUSE, a small rodent of the jerboa family, belonging to the genus *myoxus* (Gmelin); this genus has since been subdivided, with the addition of the genera *muscardinus* (Ray) and *graphiurus* (F. Cuv.). The genus *myoxus* has 2 incisors above and below, and 4 molars on each side of each jaw divided by numerous transverse bands; the eyes are large and prominent; the ears large; the whiskers long; no cheek pouches; fore feet with 4 toes and the rudiment of a 5th; hind feet 5-toed; tail long and hairy; fur soft; claws sharp. Dormice live principally on trees, eating fruits, and pass the winter in a state of lethargy, having collected a store of food for use in the spring. All are said by Cuvier to be destitute of a cæcum. The best known species are all European. The largest species, the fat dormouse or loir (*M. glis*, Linn.), is about 6 inches long, of an ashy brown above, whitish below, with brown about the eyes; the whiskers are strong; the tail is hairy its whole length, much like that of a squirrel. This animal resembles the squirrel in its manners, though it is less active, climbing trees with facility, and rarely descending to the ground; it makes a nest of moss in hollow trees, couples in the spring, and brings forth 4 or 5 at a birth; it is confined to the south of Europe, and in Italy has from remote times been used as food. As cold weather approaches, the dormouse rolls itself into a ball, and in this state is found in winter in holes of trees and clefts of rocks; if kept in a warm room during winter, it continues active like ordinary animals; when the thermometer descends to about 48° F. it begins to grow torpid, and becomes entirely so at about 42°; according to the experiments of M. Mangili of Pavia, a temperature in the neighborhood of and below 32° revives the animal. When torpid, it appears as if dead, with the eyes closed, the breathing being suspended for a period of from 5 to 20 minutes, and then renewed for from 15 to 30 respirations, with a corresponding retardation of the circulation; the nature of this state will be more fully discussed in the article Hibernation. The garden dormouse, or lerot (*M. quercinus*, Linn.), is smaller, with a thicker body, more pointed muzzle, and more thinly haired tail; the color is reddish gray above and white below, black round the eyes to the shoulders, tail black with a white tuft. As the name indicates, this species lives in gardens, and sometimes enters houses; it often does mischief in orchards, always selecting the choicest fruit; it hibernates, 8 or 10 being sometimes found together rolled up in a magazine of food; the scent is like that of the rat, and the flesh is not used as food; it is confined to temperate Europe. The common dormouse (*muscardinus avellanarius*, Linn.) is not much larger than a mouse, but the head is shorter, the muzzle less pointed, and the eyes larger; the color above is a cinnamon red, and whitish below; the tail, as long as the body and flattened horizontally, is covered with hair, quite short, and arranged on each side like the barbs of a feather. This species inhabits the woods, hibernating in the clefts of trees, and is rarely found in gardens or houses. The name dormouse, or sleeping mouse, is best applied to this species, as it most readily falls into the lethargic state, from which it is roused either by a too high or a too low temperature, becoming active in less than half an hour; when awakened, like the other species, it partakes moderately of food. One of these, exposed in a lethargic state to a cold which killed it in 20 minutes, presented on examination the heart, great vessels, and lungs distended and gorged with blood. It is found in temperate Europe, occasionally in England. The cape dormouse (*graphiurus capensis*, F. Cuv.) is found in South Africa; the length is 7¼ inches, of which the tail is 3½; the color is bluish gray above and whitish below; the muzzle and spots above and behind the ear white, behind the chin rufous; tail bushy and penniform, grayish above and blackish below. —Dormice are kept as pets, and may be fed on all kinds of grain and nuts; the inner part of the cage should be stuffed with fine hay, and the whole kept very clean; in winter they should be kept in a warm room to prevent their going to sleep.

DORN, Johannes Albrecht Bernhard, a German orientalist, born at Scheuerfeld, Saxe-Coburg, May 11, 1805. He was professor of oriental languages at the Russian university of Kharkov from 1829 to 1835, when he removed to St. Petersburg. Since 1843 he has been at the head of the imperial library, and presides over the Asiatic museum, of which he published a description in 1846. He has written several works on the Afghan language and other oriental subjects, and is noted for his knowledge of the history and geography of the Caucasus.

DORPAT, Dörpt, or Derpt, a Russian town, capital of a circle in the N. E. part of the government of Livonia; area of the latter, 4,257 sq. m.; pop. 190,000. The former is situated on the Embach, here crossed by a granite bridge; pop. in 1851, 12,683. It is on the road from Riga to St. Petersburg, and has 2 suburbs bearing the names of those cities. Its distance from the former is 150 m., and from the latter 170. It has a neat and picturesque appearance, being ranged in a semicircle, with clean, well-paved streets, and a spacious market place. The most noteworthy of the public buildings is the univer-

sity, founded in 1632, when the town belonged to Sweden, by Gustavus Adolphus, suppressed by the Russians in 1656, and reëstablished in 1802–'3 by the emperor Alexander. Connected with it are a normal school called the *Professoren-Institut*, founded in 1828, and an observatory which Tycho Brahe rendered famous, and which in modern times has derived additional celebrity from the labors of Struve and other astronomers. The university has a library of about 60,000 volumes, a museum, and a botanical garden. It is held in high repute, and students (numbering from 600 to 700) resort to it from every part of the empire. The rector of the university is now appointed by the emperor; previous to 1851 he was selected by the professors from their own body. Dorpat also contains a college founded in 1589, a number of other schools and academies, handsome law courts, and an ancient cathedral, now partly in ruins. In former times the town was fortified, but the defences have been dismantled and converted into pleasure gardens. It was founded in 1030, and anciently possessed great commercial importance, ranking as one of the Hanse towns. The Teutonic knights took it from the Russians in 1223, and erected it into a bishopric the following year. This rendered it a place of considerable note, and for upward of 3 centuries the bishop exercised almost sovereign power within his diocese. The see was abolished in 1558, when the town passed again into the hands of the Russians. The Poles seized it in 1582, and the Swedes took it from them in 1625. Peter the Great recaptured it in 1704, and it has remained ever since in the possession of Russia. The vernacular language is Esthonian, but the best educated classes speak German.

DORR, Thomas Wilson, an American politician, born in Providence, R. I., in 1805, died there, Dec. 27, 1854. He was the son of Sullivan Dorr, a successful manufacturer, was educated at Phillips academy, Exeter, N. H., and was graduated at Harvard college in 1823. He studied law in New York in the office of Chancellor Kent, was admitted to the bar in 1827, and commenced practice in Providence. Originally a federalist in politics, he became a democrat in 1837. The government of Rhode Island at that time was based upon a charter granted by Charles II. in 1663, and the apportionment of representation in the legislature was greatly at variance with the distribution of population. The elective franchise was limited to the holders of a certain amount of real estate and to their eldest sons. About one third only of the citizens were voters. Mr. Dorr was elected a member of the assembly in 1833–'4–'5–'6–'7, and exerted himself to procure the substitution of a liberal constitution in place of the old charter, but his movement for reform obtained in the legislature only 7 out of 70 votes. He resorted to popular agitation, and organized a suffrage party in opposition to the charter party. The suffrage party, after holding several large mass conventions in 1841, called a delegate state convention to frame a new constitution, which was submitted for ratification to the popular vote. It received 14,000 votes, a clear majority of the citizens of the state. The charter party, however, contended that the whole proceeding was seditious, and that a large proportion of these votes were fraudulent. Mr. Dorr and his party assumed that the new constitution was the fundamental law of the state, and proceeded in accordance with it to hold an election for state officers. Mr. Dorr was chosen governor, and a legislature composed exclusively of his supporters was elected, to meet at Providence on the first Monday of May, 1842. The charter party also held a legal election for state officers, polling 5,700 votes, while the suffrage party claimed to have polled 7,300. On May 3, Mr. Dorr's government attempted to organize at Providence and to seize the reins of power. They were resisted by the legal state government, which organized at Newport on the same day, at the head of which was Gov. Samuel W. King. Both sides appealed to arms. Gov. King proclaimed the state under martial law, called out the militia, and asked and obtained the aid of the United States to suppress the insurrection. A precept was issued for the arrest of Mr. Dorr, charged with treason. On May 18 a portion of the suffrage party assembled at Providence under arms, and attempted to seize the arsenal, but dispersed on the approach of Gov. King with a military force. They assembled again to the number of several hundred, May 25, at Chepachet, 10 m. from Providence, but being attacked by the state forces they dispersed without resistance, and the affair was over on the 28th. Mr. Dorr took refuge in Connecticut, and afterward in New Hampshire. A reward of $4,000 was offered for his apprehension by the authorities of Rhode Island. He soon returned to the state, was arrested, tried, and convicted of high treason, and sentenced to imprisonment for life. He was pardoned in 1847, and in 1853 the legislature restored to him his civil rights, and ordered the record of his sentence to be expunged. He lived to see his state under a liberal constitution, and his party in legal possession of the government.

DORSETSHIRE, a maritime co. of England, on the British channel; greatest length from E. to W. 57 m; greatest breadth, 40 m.; area, 987 sq. m.; pop. in 1851, 184,207. The seacoast is very irregular, running out in several promontories, and broken by Poole harbor and Weymouth or Melcombe Regis bay. The chief rivers are the Stour, Frome, and Piddle. The face of the country is undulating, there being no mountains, and the highest point, Pillerden Pen, being only 934 feet above the sea. A range of chalk downs, entering the county from Wiltshire on the N., passes S. W. and W. to the border of Somersetshire on the W., and is called the North downs; while a similar range, under the name of South downs, runs S. and S. E. from the W. terminus of the other, nearly par-

allel with the coast, to Poole harbor. The soil consists mainly of loose sand or gravel, interspersed with clay and chalk, and in some places mixed with these last, the conglomerate thus produced being the most fertile in the county. Beside the chalk formation, Dorsetshire contains pipe, plastic, and potters' clays, and has famous quarries of Portland stone, so called from the locality in which it is found, and which is exported to various parts of England, Ireland, and France. There are no ores nor coal. The downs are employed chiefly as sheep pastures, and it is estimated that the sheep stock amounts to 632,000, and the annual yield of wool to 10,000 packs. The Dorset sheep are noted as a profitable breed, and "Southdown mutton" has a high reputation. There is another and very small breed in the island of Purbeck, much prized by epicures. A large proportion of land is devoted to the use of the dairy. Excellent butter is made, but the cheese is of poor quality. The principal grain crops are wheat and barley. Potatoes, flax, and hemp are also raised, but husbandry is in a backward state. The manufactures comprise silk, woollens, cottons, blankets, canvas, ducks, fabrics of flax, gloves, parchment, buttons, strong beer, ale, and cider. Herrings, salmon, oysters, and large quantities of mackerel are taken off the coast. The chief towns are Dorchester, the county seat, Bridport, Lyme Regis, Weymouth, Poole, Shaftesbury, Wareham, and Sherbourne. Dorset returns 13 members to parliament, 3 of whom are for the county proper.

DORSEY, John Syng, an American physician, born in Philadelphia, Dec. 23, 1783, died Nov. 12, 1818. He was educated in his native city at a school belonging to the society of Friends, studied medicine with his relative Dr. Physick, and received the degree of M.D. in 1802. He visited France and England, and returning home in Dec. 1804, began the practice of his profession, in which his success was rapid. In 1807 he was elected adjunct professor of surgery in the Philadelphia medical school, was afterward transferred to the chair of materia medica, and having given 2 courses of lectures on that subject, was chosen to succeed Dr. Wistar in the professorship of anatomy. On the evening after delivering his introductory lecture he was attacked by a fever, and died at the end of a week, having gained at the age of 35 the reputation of one of the first surgeons of America. He contributed valuable papers to several periodicals, and published "Elements of Surgery" (2 vols. 8vo., 1813), which was adopted as a text book in the university of Edinburgh.

DORT, or Dordrecht (Lat. *Dordracum*), an ancient town of the Netherlands, in the province of South Holland, situated on an island in the Merwede, a river formed by the junction of the Meuse and the Waal; pop. in 1856, 22,000. The advantages of its position, 10 miles from Rotterdam, near the sea, accessible from the Rhine through the Waal, and having easy communication with an extensive inland district, have rendered it one of the first commercial towns of Holland. From Liége it receives coal, lime, and millstones. The vineyards on the Rhine supply it with wine, and from Switzerland and upper Germany it obtains timber, which drifts down the river in large rafts like floating islands, and is here collected, serving for ship-building and other purposes. The surrounding waters afford plenty of good fish and wild fowl. A flourishing trade is carried on in oil, seeds, grain, flax, and stock fish. There are oil mills, saw mills, salt and sugar refineries, bleaching grounds, and factories of white lead, tobacco, steel pens, and window glass. The port is excellent. There are canals leading to the interior of the town, and a number of quays. The houses have an exceedingly antiquated appearance; the windows are grotesquely ornamented, and the gable ends generally face the street. The public buildings are numerous, and some of them possess considerable historical interest. Three old houses formerly used as *doelens*, or places of rendezvous for armed burghers, are still standing. In one of these, now used as a public house, was held the famous Protestant synod of Dort, in 1618–'19, which condemned the doctrines of Arminius. The provincial synods of South Holland were held regularly in the same place until 1731, after which they convened in the great church. Another of the doelens has been converted into a court house, and a public school is taught in the third. Among the churches, the chief is St. Mary's, an immense building of great antiquity, originally used by the Roman Catholics, and then containing no less than 20 chapels and 40 altars. It has a square tower of considerable height, and a vaulted stone roof. The pulpit is a fine piece of workmanship, of white marble elaborately sculptured. The church is now held by the Protestants, who have beside 2 other places of worship. There are also a new Roman Catholic church, a congregation of Jansenists, numbering about 100, and a Jewish synagogue. The town hall is a very old building, but still in good preservation. Dort also has a corn exchange, a bank, an artillery arsenal, classical, agricultural, and other schools, an orphan asylum, alms houses, an infirmary, and a lunatic asylum. In 1421 it was involved in a terrible inundation, which is said to have swallowed up 70 villages, and to which the island of Dort owes its formation, the city having previously stood on the mainland. A conflagration in 1457 consumed upward of 2,000 houses, including many of the public edifices. At the time of the reformation the new doctrines, which were so well received in many towns of Holland, found few supporters here at first, though they were afterward received with avidity. The spot where the reformers first preached in Dort in 1572, beneath a linden tree which stood in front of one of the old doelens, is still pointed out to strangers. The first meeting of the states-general, at which the independence of the United Provinces was declared, was held here during the same year.

While the disputes about the stadtholdership were raging in 1672, the inhabitants of this town sided with the house of Orange; in 1786, when similar difficulties arose, and Prussia intervened, Dort took a decided stand against that kingdom, and succeeded in obtaining advantageous terms. During the wars of Napoleon the burghers displayed an undaunted spirit in maintaining their national independence.

DORT, Synod of. See Reformed Dutch Church.

DORTMUND, a town of Prussia, province of Westphalia, and capital of a circle of the same name; pop. in 1855, 20,000. It is enclosed by walls, has 5 gates, several churches, 2 hospitals, and some other public buildings, manufactories of woollen, linen, cotton, &c., 4 annual fairs, and a considerable trade. It was important at an early day, and was a member of the Hanseatic league, but its prosperity afterward declined. Formerly a free imperial city, it passed into the possession of the family of Nassau-Diez in 1802, and into the hands of Prussia in 1815.

DORUS-GRAS, Émilie, a French singer, born in Valenciennes in 1813. Her father, an officer under the first empire, was her earliest instructor in music, and at the age of 8 she was sent to the *conservatoire* of Paris. Having completed her education there, she made her début at Brussels in 1830; but returning to France in consequence of the revolution in Belgium, she accepted an engagement at the grand opera in Paris, where she remained upward of 20 years, most of the time in the capacity of leading prima donna. Her chief parts were in *Guillaume Tell*, *La muette de Portici*, *Fernand Cortez*, *Robert le diable*, *Les Huguenots*, and *La Juive*. Her voice has great compass and flexibility, and she is distinguished by brilliancy of execution and dramatic delivery. In 1833 she was married to M. Gras, an eminent violinist, with whom several years ago she retired from professional life.

DORY, the name of a family of scomberoid fishes, distinguished from the others of the group by having protractile mouths. This family of *zeidæ* contains the 6 genera of *zeus* (Linn.), *capros* (Lacép.), *caprophonus* (Müll. and Trosch.), *lampris* (Risso), *equula* (Cuv.), and *mene* (Lacép.) The name of dory is generally restricted to the genus *zeus* (Linn.), characterized by one dorsal fin deeply notched, or 2 contiguous dorsals of which the anterior is spinous, with delicate filaments projecting far beyond the spines; the ventrals, also spiny, are a little in advance of the pectorals; there are 2 anals, or 2 divisions of a single anal, the anterior portion being spinous and the posterior soft, like the dorsals; the caudal is distinct and rounded at the end; there are several bony dermal bifurcated plates or shields along the basis of the dorsal and anal fins; the branchiostegal rays are 7; the teeth numerous, small and feeble; the stomach large and cæcal, with very numerous pyloric cæca; air bladder large, simple, and oval. The best known species is the common or John dory (*Z. faber*, Linn.), a fish attaining a length of over 2 feet, of a grotesque form, and a yellowish tint; the body is oval, much compressed, with a smooth surface; the mouth is capable of such protrusion that the length from the point of the lower jaw to the posterior angle of the operculum may be made as great as from this angle to the base of the tail; the mouth is large, and the teeth are in a single row; the eyes are large, lateral, high up on the head, and with yellow irides; behind and over each eye is a spine. The general color is olive brown tinged with yellow, with blue, white, and golden reflections rapidly varying; on each side, very near the middle of the oval, is a round black spot surrounded by a narrow light ring. This fish was well known to the ancients, who expressed their regard for it by giving it the name of Jupiter. It has received a number of popular names, among others that of "St. Peter's fish;" with the haddock it disputes the honor of having been the species out of whose mouth this apostle took the tribute money, bearing on its sides, according to one popular tradition, the black spots indicating the marks of his finger and thumb; another tradition assigns the origin of these spots to the similar touch of St. Christopher as he bore the Saviour, wading through an arm of the sea. The name of dory has been derived from the French *adorée* (worshipped), and *dorée* (golden); the prefix of John has been derived from the French *jaune* (yellow); others consider John dory a corruption of *il janitore* (the gate-keeper), a name given to this species by the Adriatic fishermen, in allusion to St. Peter, who is often pictured as bearing the keys of the gates of heaven. From the resemblance of the first dorsal fin to a cock's comb, it has been called sea-chicken, *gal*, *gallo*, and in Gascony *jau* (cock), to which also some have traced the epithet of John, the whole name meaning the "gilt cock of the sea." This species is found in the Mediterranean, along the western coast of Europe, at the Canary islands, and on the English and Irish coasts; in England it is most common on the coasts of Devonshire and Cornwall. Its forbidding appearance has prevented it from being so much prized as an article of food as it deserves; it was highly esteemed, however, by the ancient Romans, and is now a favorite fish in many parts of England; it appears that Mr. Quin, equally famous as a comedian and an epicure, in the middle of the 18th century, first in England discovered the excellence of the dory for the table, and it is said that the English name of John dory was first given to the fish by him. It is a deep-water fish, and feeds on the fry of other species, shrimps, and mollusks; the average weight in the London market is 3 or 4 lbs., but some from the bay of Biscay have been seen weighing 12 to 16 lbs.; it often follows the pilchards, and is caught in the same nets with them; it readily takes the hook when baited with a living fish; very voracious, it seizes its prey by means of its protractile jaws, lying concealed among weeds and grasses. The elongation of

the mouth is due principally to the mobility of the intermaxillary and lower jaw bones, especially to the length of the ascending portion of the former. A second species (*Z. pungio*, Val.) is found in the Mediterranean; in this the spines of the 1st dorsal are much larger, the bifurcated spines along the 2d are 5 or 6 instead of 9 or 10, the osseous plates which bear them are stronger and more oval, and the scapular bone terminates in a large, round, pointed spine; the length is about 17 inches, and the color blackish brown. A species 2 feet long (*Z. capensis*, Val.) occurs at the cape of Good Hope; another (*Z. Japonicus*, Val.), of a grayish yellow color, with a deep blue spot, is found in Japan; and still another species in the Australian seas. In June, 1858, Dr. D. H. Storer described the first species of this genus found in American waters, in the "Proceedings of the Boston Society of Natural History" (vol. vi., p. 385); this is the spotted dory (*Z. ocellatus*, Storer), captured at Provincetown, Mass. The color is cupreous, marked with numerous more or less circular dark spots; the base of the 2d dorsal is longer than that of the 1st; along the dorsal fin are 7 bony spinous plates, along the anal 5, along the abdomen 8, and along the throat 4; the length was 6 inches.—The name of dory has been applied in this country to other scomberoid fishes of the genera *blepharis* (Cuv.), *argyreiosus* (Lacép.), and *vomer* (Cuv.), which were included by Linnæus and Bloch in the genus *zeus*, from which they were separated by Cuvier. These American dories have a very compressed body, and very singular forms. In the genus *blepharis* the body is sharp on the edges, with a brilliant smooth skin; the dorsal and anal fins have long filamentous rays from 4 to 12 inches in length, which from their resemblance to wax-ends have obtained for them in the West Indies the name of *cordonniers* (shoemakers). In the genus *argyreiosus* the 2d and 3d rays, or only the 1st, of one or both dorsals are filamentous; the great perpendicularity of the facial line gives a ridiculously solemn expression to this genus; these fishes are occasionally taken in the waters of New York, and are considered excellent articles of food. The genus *vomer* has a similar vertical profile and silvery lustre, but no filaments or prolongations of the fins; it is esteemed for food; the *V. Brownii* (Val.) of the New York coast is from 8 to 12 inches long.

DOSITHEANS, an ancient sect of the Samaritans, so called from their founder Dositheus, who was a contemporary and companion of Simon Magus, and flourished in the 1st century A. D. According to one account Dositheus was a disciple of John the Baptist, and, after the death of the latter, endeavored to place himself at the head of the followers of that prophet. Another account tells us that he tried to persuade the Samaritans to receive him as the Messiah. There were still in the 4th century a few Dositheans who adhered to their master as the true Messiah, but the sect was never of much importance.

DOUAY, or DOUAI, a town of France, capital of an arrondissement of the same name, in the department of Nord, 18 m. S. of Lille; pop. in 1856, 18,777. It is situated on the river Scarpe, and on the northern railway, thus having connection with the principal towns of France and Belgium. It is surrounded by walls, is strongly fortified, and contains several literary and scientific institutions, a public library, school of artillery, an arsenal and cannon foundery belonging to the government, and has manufactories of lace, embroidery, cotton, linen, leather, delft ware, glass, paper, refined sugar, salt, &c., several breweries, distilleries, and oil mills, and an extensive trade. Douay is a very ancient town, and, according to some, existed in the time of the Romans. It was a town of considerable importance when in possession of the counts of Flanders, from whom it came into the power of the king of Spain, and in 1667 passed into the hands of Louis XIV. Though taken by the duke of Marlborough in 1710, it was soon retaken by the French, and its possession was finally confirmed to them by the treaty of Utrecht in 1713. During the religious troubles in England in the 16th and 17th centuries, it acquired considerable celebrity as the seat of a Roman Catholic college and ecclesiastical seminary, founded by Dr. William (afterward Cardinal) Allen, for the education of English youths. Studies were commenced at this institution in 1568, and for about 10 years its prosperity was uninterrupted. But in the course of time the townspeople of Douay, then subjects of the king of Spain, grew jealous of their English neighbors, and in spite of the efforts of the magistrates to preserve peace, disturbances were of frequent occurrence. To prevent further mischief the college was removed to Rheims in 1578, where it was protected by the Guise family. In 1593 it was again established at Douay, and remained there until finally broken up by the French revolution in 1793. A translation of the Bible into English was made at this college by Dr. Gregory Martin, assisted by Dr. Allen, Dr. Richard Bristow, and Dr. John Reynolds. The New Testament was published at Rheims in 1582, and the Old Testament at Douay in 1609 and 1610. This is the translation received in the English Roman Catholic church, and known as the Rhemish or Douay version.

DOUBLEDAY, EDWARD, an English naturalist, born in 1810, died in London in 1849. At an early age he made a tour of the United States, and on his return published a paper on the "Natural History of North America," and was appointed one of the curators of the British museum. The most valuable of his contributions to science are the results of his researches concerning butterflies, published in a work "On the Genera of Diurnal Lepidoptera," which, however, he left unfinished at his death. He was also the author of a variety of papers on ornithology, entomology, and zoology, published in the "Entomological Magazine" and elsewhere.

DOUBLOON (Sp. *doblon*), a well known

gold coin of Spain and Spanish America, originally coined of the same weight and fineness as the Spanish dollar, and valued at $16. Its subdivisions in gold were the half doubloon, the quarter or *pistole*, the eighth or *escudo*, and in Spain the sixteenth or *veintein*. It is still coined in Mexico, Central America, and most of the South American states, but owing to a reduction of fineness is worth only from $15 50 to $15 60 of our money. (See Coins.)

DOUBS, a department on the E. frontier of France, named from the river Doubs, which rises in the Jura, and empties into the Saône; area, 2,020 sq. m.; pop. in 1856, 286,888. Its surface is for the most part mountainous, gradually rising from the more level country in the N. W. of the department to the rugged and sterile mountain peaks on the frontier of Switzerland. The principal rivers are the Doubs and the Oignon, though there is a large number of smaller streams. Agriculture is carried on to some extent, but the grain raised is insufficient for the wants of the inhabitants. Much attention is paid to the raising of horses and cattle, and a considerable portion of the department is devoted to pasturage. There are some iron mines, which are worked, and coal, gypsum, building stone, and salt are also produced. The manufactures comprise clocks, paper, leather, woollen and cotton cloth, iron and steel ware, butter, cheese, &c. The climate is somewhat variable, but is on the whole cold, and in the lower parts of the department much rain falls. The country is nevertheless healthy, and the inhabitants vigorous and sturdy. It is divided into 4 arrondissements. Capital, Besançon.

DOUCE, Francis, an English antiquary, born in 1762, died in London, March 30, 1834. He collected a great number of rare books, prints, medals, coins, &c., the most important of which he bequeathed at his death to the Bodleian library. His papers he gave to the British museum, on condition that the box which contained them should not be opened until the year 1900. Mr. Douce contributed some papers to the "Archæologia," and to the "Gentleman's Magazine," and was the author of "Illustrations of Shakespeare and Ancient Manners" (2 vols. 8vo., London, 1807), and a "Dissertation on the Dance of Death" (London, 1833).

DOUGHTY, Thomas, an American landscape painter, born in Philadelphia, July 19, 1793, died in New York, July 24, 1856. He was apprenticed in his youth to a leather manufacturer, and afterward carried on the business on his own account. A growing taste for art, however, induced him in his 28th year, contrary to the advice of his friends, to become a painter. He had previously attempted a few paintings in oil, which he himself has characterized as "mere daubs," and had received a quarter's tuition in India ink drawing. He practised his profession for many years in the United States, and also in London and Paris. For some years previous to his death his pencil was less active.

DOUGLAS. I. A S. W. co. of Oregon, bounded E. by the Cascade range, and drained by Umpqua river and its branches; pop. in 1858, 2,105. Organized in 1855. Capital, Winchester. II. An E. co. of Nebraska, bounded E. by the Missouri, which separates it from Iowa, and W. by the Platte river. It is drained by Elkhorn, Big Papillon, and Little Papillon rivers. Capital, Omaha City. III. An E. co. of Kansas, bounded N. by Kansas river, and drained by the Waukarusa; area, 500 sq. m.; pop. in 1859, about 12,000. It consists chiefly of rolling uplands, with a black loamy soil, well timbered, and producing Indian corn, wheat, oats, potatoes, sorghum, and hemp. The minerals are coal and carboniferous limestone. The county was settled in 1854, and its name was changed to Lincoln in 1859. Chief towns, Lawrence and Lecompton; the latter is the capital of the territory.

DOUGLAS. I. A seaport town on the E. coast of the isle of Man; pop. in 1851, 9,880. It is the capital of the island, and a watering place of much resort. It has a harbor capable of admitting vessels of 10 or 12 feet draught at high water, and a pier 520 feet in length. Steamers from Liverpool, Glasgow, and various ports of Ireland, often touch here. Ship-building is carried on to some extent, and many of the inhabitants are employed in the coasting trade and the fisheries. II. A village and parish of Lanarkshire, Scotland, on a river of the same name; pop. in 1851, 2,611. The parish is owned almost entirely by the heir-at-law of the Douglas family, who takes from this place his title of baron. The duke of Hamilton is marquis of Douglas. Near the village are the ruins of the ancient church of St. Bride, noted for its numerous family tombs, among which is a monument to "the good Lord James," the friend of Robert Bruce and the hero of Sir Walter Scott's tale, "Castle Dangerous."

DOUGLAS, a Scottish family, once so powerful that it passed into a proverb: "No man may touch a Douglas, nor a Douglas's man, for if he do, he is sure to come by the waur (worse)." The family has been connected with the most distinguished nobles of England, Scotland, France, and Sweden, and has intermarried 11 times with the royal houses of Scotland, once with that of England, and in 1841 with a princess of Baden. It held for a time the earldom of Athol, and one of its members acquired in the 14th century the title of earl of Douglas and Mar. The earls of Angus afterward became the heads of the family, and the 11th of that title was created marquis of Douglas in 1633, while another branch acquired the earldom of Queensberry. The 3d marquis was made a duke, but dying without issue the title of marquis of Douglas fell to the duke of Hamilton, and the chief dignities of the family are now held by the houses of Buccleugh and Queensberry. Baron James Douglas of Douglas was a son of Archibald Stewart, nephew of Archibald, duke of Douglas, whose legitimacy was contested by the duke of Hamilton; it being alleged on Stewart's behalf that he was one of a pair of twins born in Paris,

July 10, 1748, when his mother was in her 51st year; the other twin was said to have died in infancy. The Scotch courts determined in favor of Hamilton, but the house of lords reversed the judgment. This suit, known as the Douglas case, was one of the most extraordinary ever litigated in Great Britain. Mr. Stewart was elevated to the peerage as Baron Douglas in 1790. Baron James, the late peer, died April 6, 1857, when this title became extinct, and the estates devolved on his half sister, Lady Montagu. Among the present representatives of the great Douglas family is Sir Robert Douglas, an officer in the army, born July 19, 1837.

DOUGLAS, David, a British botanist, born in Scone, Scotland, in 1798, killed in the Sandwich islands, July 12, 1834. Having been employed as a laborer in the Glasgow botanic garden, his intelligence attracted the notice of Dr. (afterward Sir William) Hooker, who procured for him an appointment as botanical collector to the horticultural society of London. In this capacity he travelled extensively in America; in 1824 explored the Columbia river and California, and in 1827 traversed the continent from Fort Vancouver to Hudson's bay, where he met Sir John Franklin, and returned with him to England. He made a second visit to the Columbia in 1829, and afterward went to the Sandwich islands. His death was caused by falling into a pit made to entrap wild cattle, where he was killed and mutilated by an animal previously entrapped. Through his agency 217 new species of plants were introduced into England. He collected 800 specimens of the California flora. A gigantic species of pine which he discovered in California is named after him *pinus Douglasii*.

DOUGLAS, Gawin, or Gavin, a Scottish poet, bishop of Dunkeld, youngest son of Archibald, 5th earl of Angus, born in Brechin about 1474, died of the plague in London in 1521 or 1522. He was educated for the church, partly in Scotland and partly at Paris, and when 22 years of age was appointed rector of Hawick. While in this office he translated into verse Ovid's "Remedy of Love." In 1501 he addressed to King James IV. the "Palace of Honor," an allegory which resembles so much in structure the "Pilgrim's Progress," that Bunyan has been thought to have borrowed the idea of his work from that of the Scotch bishop. In 1509 he was appointed provost of St. Giles's, Edinburgh. At the solicitation of Lord Sinclair, who afterward fell at Flodden, he translated the Æneid into Scottish verse. The original issue bears the title page: "The xiii. bukes of Eneados of the famose poet Virgill, translatet out of Latyne verses into Scottish metir, bi the Reuerend Father in God, Mayster Gawin Douglas, Bishop of Dunkel, & vnkil to the Erle of Angus: euery buke hauing hys perticular prologe" (4to., London, 1553). This work was written in 16 months and finished in 1513, though first printed 40 years later. It is praised for its spirit and fidelity. The 13th book was the production of Mapheus Vegius. In Sept. 1513, "the provost of St. Giles," as he was now called, accompanied the king to Flodden field, where his 2 elder brothers, the master of Angus and Sir William Douglas, with 200 gentlemen of their name, were slain. Soon afterward the earl his father died of grief. The chief of Douglas was now the young earl of Angus, nephew of Gawin. This youth married the queen regent, and was the means of Gawin's obtaining the abbacy of Aberbrothwick, and a nomination to the archbishopric of St. Andrew's, which would have made him head of the church in Scotland. The pope would not assent to this appointment, and as the partisans of the various candidates appealed to arms, it ended in Gawin's abbacy being taken from him. Thereupon the queen made him bishop of Dunkeld, in 1515. On taking possession of his see he found it in armed possession of the earl of Athol's brother, Andrew Stewart. Douglas's friends rallied in force and took the cathedral, after which the contention went on for years between the rival families of Angus and Hamilton, and in April, 1520, both families met in Edinburgh to fight it out. Bishop Gawin, foreseeing bloodshed, besought Beaton, archbishop of Glasgow, a partisan of the Hamiltons, to prevent the fray. The archbishop, who was in canonical habit, struck his hand on his breast and declared on his conscience that he knew nothing of any attempted violence. Unfortunately the archbishop had armor under his gown, intending himself to take part in the fight; his gesture of asseveration caused the steel to clash. "Methinks," said Douglas drily, "your conscience clatters." Douglas's intercessions were of no avail; the forces of the rival lords met. Hamilton was defeated, and the bishop had the revenge, later in the day, of saving the life of Beaton, whom the victors were about to slay on the altar of Blackfriars' church. Next year the regent Albany called the Angus party to account, and the earl, with Gawin and the chief men of his name, were forced to fly to England, where Henry VIII. received them well, and allowed Gawin a pension. An allegorical poem of his, entitled "King Hart," was left in manuscript, and published by Pinkerton in his "Ancient Scottish Poems," 1788. According to Hallam, "the character of Douglas's original poetry seems to be that of the middle ages in general—prolix, though sometimes animated, description of sensible objects." Warton thinks, on the contrary, that his metrical prologues are "often highly poetical, and show that Douglas's proper walk was original poetry."

DOUGLAS, Sir Howard, an English general, born in Gosport, Hampshire, July 1, 1776. He entered the army at an early age, served in Walcheren, and in the Spanish and Portuguese campaigns in 1808–'9–'11–'12. He succeeded his brother as 3d baronet, May 24, 1809. In 1823 he was appointed governor of New Brunswick, and held that office until 1829, in which year he received the degree of D.C.L. from the university of Oxford. He was lord high commissioner

of the Ionian islands from 1835 to 1840, and member of parliament for Liverpool from 1842 to 1847. He was raised to the rank of general in 1851. Sir Howard is the author of several valuable works on military science, among which are an essay "On the Construction of Military Bridges," &c. (1817), and "A Treatise on Naval Gunnery" (1819). In a 4th edition of the latter work, published in 1855, he reviewed very severely the military operations in the Crimea.

DOUGLAS, John, D.D., an English prelate, born in Pittenweem, Fifeshire, Scotland, in 1721, died in Salisbury, May 18, 1807. He was chaplain to a regiment of foot guards serving in Flanders, was present at the battle of Fontenoy (1745), and was employed by Gen. Campbell in carrying orders. After having held various ecclesiastical benefices, chiefly through the patronage of the earl of Bath, in 1781 he was chosen president of Sion college; in 1787 was made bishop of Carlisle; in the succeeding year became dean of Windsor; and in 1792 was translated to the see of Salisbury. He was a member of the royal society, and vice-president of the antiquarian society. Beside an early literary effort entitled "A Vindication of Milton from the charge of Plagiarism," Dr. Douglas wrote many religious and political pamphlets. He also superintended in 1762 the publication of the 2d Lord Clarendon's "Diary and Letters;" in 1777, Lord Hardwick's "Miscellaneous Papers," and Capt. Cook's second voyage; and in 1781, Capt. Cook's last voyage. His religious writings were several anniversary sermons; the "Criterion, or Miracles Examined," intended as a vindication of the Christian miracles from the attacks of Hume; with sundry controversial discourses against the Hutchinsonians, Methodists, and other sects. He was a member of the club instituted by Dr. Johnson, and is accordingly mentioned by Boswell and Goldsmith.

DOUGLAS, Stephen Arnold, an American statesman, born at Brandon, Rutland co., Vt., April 23, 1813. His father was a native of the state of New York, and a physician of considerable reputation. He died suddenly of apoplexy when his son Stephen Arnold was but little more than 2 months old. The widow, with her infant and a daughter only 18 months older, retired to a farm which she had inherited conjointly with an unmarried brother. At the age of 15 her son, who had received a good common school education, desired to prepare for college; but his family proving unable to bear the requisite expense, he left the farm, determined to earn his own living, and engaged himself as an apprentice to the trade of cabinet making, at which he worked a year and a half, partly at Middlebury and partly at Brandon, when his health became so impaired by the severity of the labor that he abandoned the occupation altogether. He has often since said that the happiest days of his life were passed in the workshop. He now entered the academy at Brandon as a student, and remained there a year. His mother about this time was married to Mr. Granger, of Ontario co., N. Y., to whose son her daughter had been previously married. Young Douglas removed with his mother to Canandaigua, and entered as a student the academy of that place, in which he continued till 1833. He studied law in the office of the Messrs. Hubbell, at the same time that he pursued his academical course, having finally adopted that as his profession. In the spring of 1833 he went to the West in search of an eligible place in which to establish himself as a lawyer. At Cleveland he was detained the whole summer by severe illness, after his recovery from which he went to Cincinnati, Louisville, St. Louis, and Jacksonville, Ill. At Jacksonville he found his funds reduced to 37½ cents, and accordingly walked to Winchester, a little town 16 miles distant, where he hoped to get employment as a school teacher. He found there a large crowd assembled to attend the auction sale of the stock of a deceased trader. The auctioneer was without a clerk to keep the account of the sale, and perceiving that Mr. Douglas, who stood among the spectators, looked like a man who could write and keep accounts, requested him to serve in that capacity. Mr. Douglas consented, and acted as clerk during the three days of the sale, receiving for his services $6. With this capital in hand he promptly opened a school, and obtained 40 pupils, whom he taught for 3 months at $3 a quarter, devoting his evenings to the study of some law books which he had borrowed in Jacksonville, and on Saturday afternoons practising in petty cases before the justice of peace of the town. In March, 1834, he opened an office and began practice in the higher courts, for which, after examination, he had obtained license from the judges of the supreme court. He was remarkably successful at the bar, as may be inferred from the fact that within a year from his admission, while not yet 22 years of age, he was elected by the legislature attorney-general of the state. This office he resigned in Dec. 1835, in consequence of having been elected to the legislature by the democrats of Morgan co. He took his seat in the house of representatives, the youngest member of that body. In 1837 he was appointed by President Van Buren register of the land office at Springfield, Ill., a post which he resigned in 1839. In Nov. 1837, Mr. Douglas received the democratic nomination for congress, although he was under 25 years of age, and consequently ineligible. He however attained the requisite age before the day of election, which was the 1st Monday in Aug. 1838. His congressional district was then the most populous one in the United States, and the canvass was conducted with extraordinary zeal and energy. Upward of 36,000 votes were cast, and the whig candidate was declared to be elected by a majority of 5 only. A number of ballots sufficient to have changed the result were rejected by the canvassers because the name of Mr. Douglas was incorrectly spelled. After this defeat, which under the circumstances was claimed by his friends as a victory,

Mr. Douglas devoted himself exclusively to his profession until 1840, when he entered into the famous presidential campaign of that year with so much ardor that he traversed the state in all directions for 7 months, and addressed more than 200 political gatherings. To his exertions was ascribed the adherence of Illinois at that election to the democratic party. In Dec. 1840, Mr. Douglas was appointed secretary of state of Illinois. In Feb. 1841, he was elected by the legislature a judge of the supreme court, which office he resigned in 1843 to accept the democratic nomination for congress, which was urged upon him against his known wishes, on the ground that he was the only democrat who could be elected. After a spirited canvass Mr. Douglas was chosen by upward of 400 majority. He was reëlected in 1844 by a majority of 1,900, and again in 1846 by nearly 3,000 majority. He did not, however, take his seat under the last election, having in the mean time been chosen to the senate of the United States for 6 years from March 4, 1847. In the house of representatives Mr. Douglas was prominent among those who, in the Oregon controversy with Great Britain, maintained that our title to the whole of Oregon up to lat. 54° 40′ was "clear and unquestionable." He declared that "he never would, now or hereafter, yield up one inch of Oregon, either to Great Britain or any other government." He advocated the policy of giving notice to terminate the joint occupation; of establishing a territorial government over Oregon, protected by a sufficient military force; and of putting the country at once in a state of preparation, so that if war should result from the assertion of our just rights, we might drive "Great Britain and the last vestiges of royal authority from the continent of North America, and make the United States an ocean-bound republic." He denied the right of the federal government to prosecute a system of internal improvements in the states, though he maintained the constitutionality and expediency of improving rivers, harbors, and navigable waters, and advocated a scheme of tonnage duties for that purpose, to be levied and expended by the local authorities. He was mainly instrumental in securing the passage of the law extending the maritime and admiralty jurisdiction of the federal courts over the great chain of northern lakes, having reported the bill as a member of the judiciary committee, and put it upon its passage, when a member of the house of representatives. He was among the earliest advocates of the annexation of Texas, and after the treaty for that object had failed in the senate, he was one of those who introduced propositions, in the form of joint resolutions, as a substitute for that treaty. As chairman of the committee on territories in 1846 he reported the joint resolution declaring Texas to be one of the United States of America, and he vigorously sustained the administration of President Polk in the measures which it adopted for the prosecution of the war with Mexico, which was the ultimate consequence of that act. As chairman of the territorial committee, first in the house of representatives, and afterward in the senate, he reported and successfully carried through the bills to organize the territories of Minnesota, Oregon, New Mexico, Utah, Washington, Kansas, and Nebraska, and also the bills for the admission into the Union of the states of Iowa, Wisconsin, California, Minnesota, and Oregon. So far as the question of slavery was involved in the organization of territories and the admission of new states, he early took the position that congress should not interfere on the one side or the other, but that the people of each territory and state should be allowed to form and regulate their domestic institutions to suit themselves. In accordance with this principle he opposed the "Wilmot proviso" when first passed in the house of representatives in 1847, as an amendment to the bill appropriating $3,000,000 to enable President Polk to make a treaty of peace with Mexico, and afterward in the senate when offered as an amendment to the bill for the organization of the territory of Oregon. In August, 1848, however, he offered an amendment to the Oregon bill, extending the Missouri compromise line indefinitely westward to the Pacific ocean, in the same sense and with the same understanding with which it was originally adopted in 1820, and extended through Texas in 1845, prohibiting slavery in all the territory north of the parallel of 36° 30′, and by implication recognizing its existence south of that line. This amendment was adopted in the senate by a decided majority, receiving the support of every southern, together with several northern senators, but was defeated in the house of representatives by nearly a sectional vote. The refusal of the senate to adopt the policy of congressional prohibition of slavery in all the territories, and the rejection in the house of representatives of the proposition to extend the Missouri compromise to the Pacific ocean, gave rise to the sectional agitation of 1849–'50, which was temporarily quieted by the legislation known as the compromise measures of 1850. Mr. Douglas supported these measures with zeal and vigor; and on his return to his home in Chicago, finding them assailed with great violence, he defended the whole series in a speech to the people (Oct. 24, 1850) which is regarded by his friends as one of the ablest he has ever made. In this speech he defined the principles on which the compromise acts of 1850 were founded, and upon which he subsequently defended the Kansas-Nebraska bill, in these words: "These measures are predicated on the great fundamental principle that every people ought to possess the right of framing and regulating their own internal concerns and domestic institutions in their own way. . . . . These things are all confided by the constitution to each state to decide for itself, and I know of no reason why the same principle should not be extended to the territories." Mr. Douglas was an unsuccessful candidate before the democratic national convention at Baltimore

in 1852, for the nomination for the presidency. On the 30th ballot he received 92 votes, the highest number given to any candidate on that ballot, out of a total of 288 votes. At the congressional session of 1853–'4, he reported from the committee on territories the celebrated bill to organize the territories of Kansas and Nebraska, which effectually revolutionized political parties in the United States, and formed the issues upon which the democratic and republican parties became arrayed against each other. The passage of this bill caused great excitement in the free states of the Union, and Mr. Douglas as its author was widely and vehemently denounced, and in many places was hanged and burned in effigy. The whole controversy turned on the provision repealing the Missouri compromise, which Mr. Douglas maintained to be inconsistent with the principle of non-intervention by congress with slavery in states and territories. After repealing the Missouri restriction, the bill declared it to be the "true intent and meaning of the act, not to legislate slavery into any state or territory, nor to exclude it therefrom, but to leave the people thereof perfectly free to form and regulate their domestic institutions in their own way, subject only to the constitution of the United States." Whatever diversity of opinion may exist in regard to the correctness of this principle and the propriety of its application to the territories, it must be admitted that Mr. Douglas has proved faithful to it under all circumstances, and defended it whenever assailed or violated. In 1856 Mr. Douglas was again a candidate for the presidential nomination before the democratic national convention at Cincinnati. The highest vote he received was on the 16th ballot, which stood, for Mr. Buchanan 168, for Mr. Douglas 121, for Mr. Cass 6. In the congressional session of 1857–'8, he denounced and opposed with energy and ability the Lecompton constitution, upon the distinct ground that it was not the act and deed of the people of Kansas, and did not embody their will. Before the adjournment of that session of congress he returned home to vindicate his action before the people of Illinois in one of the most exciting and well-contested political canvasses ever known in the United States. He had to encounter the determined hostility of the federal administration and all its patronage, and the powerful opposition of the republican party. But he succeeded in carrying the election of a sufficient number of state senators and representatives to secure his return to the U. S. senate for 6 years from March 4, 1859, by 54 votes for him to 46 for Abraham Lincoln, his able and distinguished opponent. It was manifest, however, by the popular vote for certain state officers who were chosen simultaneously with the members of the legislature, that a majority of the people were opposed to Mr. Douglas. The republican candidate for superintendent of common schools received 124,566 votes; the Douglas candidate for the same office, 122,413; and the Buchanan or administration candidate, 5,173. During the whole of that contest he maintained and defended the doctrine of non-intervention and popular sovereignty, in the same sense in which he had previously proclaimed it in congress. Subsequently, in a debate in the senate (Feb. 23, 1859), he avowed and defended the same doctrine when assailed by several of the ablest senators of the democratic party.—Mr. Douglas has been remarkably successful in promoting the local interests of his own state during his congressional career. To him, more than to any other individual, is Illinois indebted for the magnificent grant of lands which secured the construction of the Illinois central railroad, and contributed so much to restore the credit and develop the resources of the state. He has always been a warm supporter and advocate of a railroad from the Mississippi river to the Pacific ocean, having been a member of the various select committees of congress on that subject, and being the author of several bills reported by those committees. Mr. Douglas's views in regard to our foreign relations have seldom been in accordance with the policy of the administration. He opposed the treaty with England limiting the Oregon territory to the 49th parallel, contending that England had no rights on that coast, and that the United States should never recognize her claim. He opposed the treaty of peace with Mexico on the ground that the boundaries were unnatural and inconvenient, and that the provisions in regard to the Indians could never be executed. The United States have since paid Mexico $10,000,000 to change the boundaries and relinquish the stipulations in regard to the Indians. He opposed the ratification of the Clayton and Bulwer treaty, and endeavored to procure its rejection, upon the ground, among other things, that it pledged the faith of the United States in all time to come never to annex, colonize, or exercise dominion over any portion of Central America. He declared that he did not desire to annex that country at that time, but maintained that the isthmus routes must be kept open as highways to the American possessions on the Pacific, that the time would come when the United States would be compelled to occupy Central America, and that he would never pledge the faith of the republic not to do in the future in respect to this continent what its interests and safety might require. He has also declared himself in favor of the acquisition of Cuba whenever the island can be obtained consistently with the laws of nations and the honor of the United States.—Mr. Douglas was married, April 7, 1847, to Miss Martha D. Martin, daughter of Col. Robert Martin of Rockingham co., N. C., by whom he had 3 children, 2 of whom are living. She died Jan. 19, 1853. He was again married, Nov. 20, 1856, to Miss Adèle Cutts, daughter of James Madison Cutts of Washington, D. C., second controller of the treasury.

DOUGLASS, David Bates, LL.D., an Amer-

ican engineer, born in Pompton, N. J., March 21, 1790, died in Geneva, N. Y., Oct. 19, 1849. He was graduated at Yale college in 1813, entered the army as 2d lieutenant of engineers, and was stationed at West Point. In the summer of 1813 he was ordered to the Niagara frontier, and arrived just in time to take part as a volunteer in the battle of Niagara. In the subsequent defence of Fort Erie, in August and September, he distinguished himself, and was at once promoted to a first lieutenancy, with the brevet rank of captain. He was ordered to West Point, Jan. 1, 1815, and made assistant professor of natural and experimental philosophy. In 1819 he acted during the summer recess as astronomical surveyor of the boundary commission from Niagara to Detroit, and in the summer of 1820 accompanied Gov. Cass in a similar capacity to the northwest. In August of the same year, while on this duty, he was promoted to the professorship of mathematics in the military academy at West Point, vacant by the death of his father-in-law, Prof. Andrew Ellicott, with the rank of major in the army. In 1823 he was transferred at his own desire to the professorship of civil and military engineering. The science of engineering was then new in this country, and few great works had been executed. He devoted himself to it with unsparing energy, and soon acquired a wide reputation. Many advantageous offers were made him, but he chose to remain at West Point. He was however employed by the state of Pennsylvania during the summer recesses from 1826 to 1830 as a consulting engineer, and charged with the surveys of several of the more difficult parts in its system of public works. In 1831 he resigned his professorship, and became chief engineer of the Morris canal, residing in Brooklyn. In 1832 he was appointed professor of civil architecture in the new university of the city of New York, and prepared the designs for its building. In June, 1833, he commenced his surveys for the great work of supplying New York with water, and in November submitted his first report, demonstrating the feasibility of such a supply, and showing how to obtain it from the Croton river. He reviewed his surveys in 1834, and prepared plans and estimates for the city authorities, and the next spring it was determined by a vote of the citizens that the aqueduct should be built. Water commissioners were appointed, and Major Douglass was at once elected chief engineer, and proceeded to lay out minutely the line of the aqueduct and complete his plans. He had accomplished his preliminary work when he was superseded. In 1839 he planned and laid out Greenwood cemetery. In 1840 he was elected president of Kenyon college, Ohio, and removed to Gambier in the spring of 1841. He withdrew from this office in 1844, and returned to the vicinity of New York. In 1845 he delivered a course of lectures at New Haven on the Niagara campaign. They had been originally delivered in New York in 1839, and soon afterward repeated at Albany during the session of the legislature, in the hall of assembly, and at Buffalo. In 1845–'6 he laid out the cemetery at Albany, and in 1847 was employed in developing the landscape features of Staten island. In 1848 he laid out the Protestant cemetery at Quebec, and in the same year he was elected professor of mathematics and natural philosophy in Geneva college. He accepted the office, and entered upon its duties in October, but died the next year. His published writings consist chiefly of reports on the numerous works on which he was employed, and which he projected.

DOUGLASS, Frederick, an American abolitionist, born at Tuckahoe, near Easton, Talbot co., Md., about 1817. His mother was a negro slave and his father a white man. He was reared as a slave on the plantation of Col. Edward Lloyd, until at the age of 10 he was sent to Baltimore to live with a relative of his master. He secretly taught himself to read and write, was employed in a ship yard, and, in accordance with a resolution long entertained to achieve his freedom, at the age of 21 fled from Baltimore and from slavery, Sept. 3, 1838. He made his way to New York and thence to New Bedford, where he married and lived for 2 or 3 years, supporting himself by day labor on the wharves and in various workshops. In the summer of 1841 he attended an anti-slavery convention at Nantucket, and made a speech which was so well received that at the close of the meeting he was offered and accepted the position of agent of the Massachusetts anti-slavery society, to deliver public addresses on slavery. In this capacity he travelled and lectured through Massachusetts and other New England states for 4 years. In 1845 he published an autobiography, entitled the "Life of Frederick Douglass," and soon after its appearance he went to Europe and lectured on slavery to crowded audiences in nearly all the large towns of England, Ireland, Scotland, and Wales. In 1846 his friends in England contributed £150 to buy him from his claimant in Maryland, and have him regularly manumitted in due form of law. He remained 2 years in Great Britain, and on his return to the United States in 1847 he began at Rochester, N. Y., the publication of "Frederick Douglass's Paper," a weekly journal which he still continues to edit. Mr. Douglass, at the beginning of his public career as a lecturer and editor, was a Garrisonian disunionist. Several years ago, however, he renounced disunionism, and now maintains in his paper and in his public addresses that slavery is illegal and unconstitutional. In 1855 he rewrote and enlarged his autobiography, under the title of "My Bondage and my Freedom," of which the 18th thousand was published at New York and Auburn in 1857.

DOURO, or Duero, one of the largest rivers of the Spanish peninsula, rises on the frontiers of the provinces of Soria and Burgos, and flows into the Atlantic at Oporto. Its current is rapid, and its course, for the most part, through nar-

row valleys. For a considerable distance it forms the boundary between Spain and Portugal. It is navigable for small vessels as far as the Spanish frontier, and receives the waters of the Pisuerga, Seco, Esla, Sabor, Tua, Tamega, Adaja, Tormes, Turon, Coa, and Tavora, beside many smaller streams. Navigation is often interrupted by freshets, and the river is but little used for commercial purposes. On its banks are the vineyards which produce the celebrated wines of Oporto. Its length, including windings, is estimated at from 400 to 500 miles.

DOUVILLE, Jean Baptiste, a French traveller and naturalist, born in Hambie, Feb. 15, 1794. The death of a rich relative gave him the means of gratifying a taste for adventure, and he travelled in Europe, South America, and Asia, landing at Genoa on his return in 1824. In 1826 he went to Paris, where he was made member of the geographical society. He sailed from Havre, Aug. 6 of the same year, for Buenos Ayres, where he arrived Oct. 29. The La Plata was at that time under blockade by the Brazilians, and the French vessel was captured while endeavoring to violate it; but Douville was befriended by the Brazilian admiral, and after a short sojourn at Montevideo, was sent to Buenos Ayres, where, finding his resources nearly exhausted, he attempted to replenish them by mercantile operations. Having been accused of some fraudulent transaction in business, of which he was afterward acquitted, he left Buenos Ayres in disgust, and went to Rio Janeiro, Aug. 1827. On Oct. 15 he embarked for Congo, whence he returned to France in 1831. The stories of his discoveries in several kingdoms hitherto almost unknown to Europeans, and of his exploration of the Congo or Zaire and other rivers, aroused great enthusiasm among the Parisians. He received a medal from the geographical society; his researches were published under the title of *Voyage au Congo et dans l'Afrique équinoxiale* (4 vols., with a map, Paris, 1832), and his book and chart were used as the basis of subsequent maps of Africa. But the evident exaggeration of some of his statements soon awakened suspicion. The English "Foreign Quarterly Review" assailed him as an impostor, and a few weeks later his deceptions were more fully exposed in the *Revue des deux mondes*. To cover his shame by real discoveries, he sailed for Brazil in 1833, and penetrated to the interior of South America, by the Amazon. Nothing has since been heard of him. Recent discoveries in Africa prove the truth of the accusations against him, although it is supposed that he reached the interior of that country, or that at least he obtained his information from Portuguese documents before unpublished; and some geographers of repute still credit a portion of his narrative.

DOUW, or Dow, Gerard, a Dutch painter, born in Leyden in 1613, died there in 1680. He had been engaged for some time in painting on glass, when he became a pupil of Rembrandt, under whom he studied for 3 years. He began with portrait painting, but was so extremely slow in finishing that no one would submit to the tediousness of sitting to him. He then devoted himself to painting domestic scenes. He was so exact in the imitation of objects, that a glass is needed to appreciate the skill and delicate finish of his work. His drawing was neither bold nor correct, but his figures are not wanting in life and expression, and his coloring is strong, fresh, and harmonious. He shared none of the poetical taste of his master, for his pictures generally consist of 2 or 3 figures engaged in the most trivial and often disagreeable occupations, as many of their titles indicate. Among the most celebrated are the "Dropsical Woman," the "Village Grocer's Wife," the "Dentist," and the "Violin Player." His works are to be found in all the public galleries of Europe, but private fortunes were hardly sufficient to command them, for it was the rule of Douw to be paid for his pictures according to the time they cost him.

DOVE, a river of England, noted for its picturesque scenery. It rises near Buxton, among the hills of the Peak of Derbyshire, and falls into the Trent, after a southerly course of 39 miles. Near the town of Ashbourne it flows through a remarkable winding chasm 2 miles in length, called Dovedale.

DOVE, Heinrich Wilhelm, a German meteorologist, born in Liegnitz, Prussian Silesia, Oct. 6, 1803. He was educated at Breslau and Berlin, in 1826 became a teacher and subsequently a professor extraordinary in the university of Königsberg, and in 1829 was invited to Berlin, where he has since filled the professorship of physics. For a series of years he has devoted much attention to the investigation of the laws which regulate atmospheric phenomena, and which he has evolved with clearness and precision. His reports and isothermal maps, prepared from an immense number of isolated observations, afforded the first representation of the isothermal lines of the whole globe for every month of the year, beside much kindred information, the importance of which to meteorologists can scarcely be overestimated. His investigations on the thermal influence of the gulf stream and on kindred subjects have also attracted the favorable notice of scientific men. As an experimenter in electricity he was the first to announce the presence of a secondary current in a metallic wire, at the moment that the circuit of the principal current is completed. Of his works, many of which have appeared in the "Transactions" of the Berlin academy of sciences, and in Poggendorf's *Annalen*, the principal are: *Ueber Mass und Messen; Meteorologische Untersuchungen; Ueber die nicht periodischen Aenderungen der Temperaturvertheilung auf der Oberfläche der Erde; Untersuchungen im Gebiete der Inductionselektricität; Temperaturtafeln; Monatsisothermen*, &c. In a more popular style he has written several treatises on meteorological and electrical phenomena, which have found many readers. In the

capacity of director of the Prussian observatories he publishes each year the results of their labors. Among his most recent writings are *Klimatologische Beiträge* (Berlin, 1857).

DOVER. I. A city and capital of Strafford co., N. H., situated 12 m. from the ocean, on both sides of the Cocheco river, 68 m. N. of Boston, and 12 m. N. W. of Portsmouth; pop. in 1775, 1,666; 1820, 2,871; 1830, 5,449; 1840, 6,458; 1850, 8,166; 1859, about 9,200. The Cocheco river runs through the township, and furnishes great motive power, the principal fall being 32½ feet. The supply of water is maintained through the dry season by draining Bow pond in the town of Strafford, which has been converted into an immense reservoir. The falls are situated at the head of tide water, to which point the river is navigable for sloops and schooners. The Cocheco company is one of the oldest incorporated manufacturing companies in the United States, and its operations have been among the most successful. It has 4 large mills for the manufacture of print cloths, also a large printery and machine shop, turning out about 9,000,000 yards per annum, and employing about 2,000 persons, the majority of whom are females. The mills are in the form of a quadrangle, and make an imposing appearance. There is also a mill for the manufacture of woollens, also an iron foundery, several tanneries, and other manufactures. The total capital employed is about $2,500,000. Black river, in the south part of the town, a smaller stream, furnishes water power which is used by establishments for the manufacture of flannels, carriages, and for various other mechanical employments. The town was settled in 1623 by the Laconia company of fishmongers of London, and is the oldest in the state. The first settlement was made on the tongue of land formed by the union of Cocheco and Piscataqua rivers. The settlement at "Strawberry Bank," or Portsmouth, was made about the same time, on the bank of the Piscataqua, a short distance down the river. It is one of the most fertile townships in the state, and the farms are in a high state of cultivation. The city is regularly laid out, and contains many elegant private residences. It is connected with Boston and Portland by the Boston and Maine railroad, and also with Winnepiseogee lake by the Cocheco road; the last named is a favorite route to the White mountains. The 3d Congregational church in the state was organized in this town about 1638. The first church edifice in the state stood on the ridge of land which rises gradually from the Piscataqua river, and was surrounded by palisades as a protection from the Indians. Jeremy Belknap, the first historian of the state, and the author and editor of several important works, was pastor of the church for 20 years from 1767 to 1787. There are 10 churches in the town, and about 70 stores. The city hall is a commodious and substantial brick edifice. The schools are excellent, and the high school building recently erected is one of the finest in the state. A monthly magazine and 3 weekly newspapers are published here. II. A post town, capital of the state of Delaware and of Kent co., on Jones's creek, 5 m. above Delaware river; pop. in 1850, 4,207. It is regularly built, mostly of brick, on high ground, 50 m. S. from Wilmington, and 114 N. E. from Washington. The streets are wide, straight, and cross each other at right angles. The principal public buildings face an open square, the E. side of which is occupied by a handsome state house. In 1850 there were 4 churches, 2 large hotels, a newspaper office, an academy, 9 schools, 3 grist mills, and 2 saw mills. The town contains a monument to the memory of Col. John Haslett, who fell in the battle of Princeton, a telegraph office, and one bank. The line of the Delaware, New Castle and Wilmington, and Wilmington and Frenchtown railroads, from Philadelphia to Seaford, passes through it. The trade is chiefly in flour with Philadelphia. III. A village and township of Tuscarawas co., Ohio, on the right bank of Tuscarawas river, near the mouth of Sugar creek, 98 m. S. from Cleveland; pop. of the township in 1850, 3,248; of the village in 1853, 1,500. It is regularly laid out, on the W. side of the Ohio canal, across which and the river there is a bridge 346 feet long. It is the shipping point for large quantities of wheat and flour; in 1851 the amount was stated at 534,415 bushels of wheat, and 40,495 barrels of flour. The town has great facilities for manufacturing, and in 1854 contained a woollen factory, 2 furnaces, 3 tanneries, a saw mill, 2 grist mills, and churches of 6 denominations. The name of its post office is Canal Dover.

DOVER (Fr. *Douvres;* anc. *Dubris*), a parliamentary and municipal borough, cinque port, and fashionable watering place of Kent, England, situated on the N. W. shore of the strait of Dover; pop. in 1851, 22,244. It is built mainly in a valley, partly encompassed by an amphitheatre of chalk hills, cliffs, and downs, on which stand a castle, a citadel, and several fortresses. The castle, an immense structure, whose walls enclose 35 acres of ground, is supposed to have been founded by the Romans. Other portions, however, are of Norman and Saxon construction, while others again belong to still later epochs. It contains a spacious keep, used as a magazine and considered bomb-proof, and barracks for 2,000 men, beside which extensive barracks for the officers, outside of the castle, were erected in 1857. Within the precincts of the castle stands an octagonal watch tower, interesting not only as the earliest specimen of Roman architecture, but also as one of the most ancient pieces of regular mason-work in Great Britain. In the time of Edward the Confessor Dover castle was considered the key to the whole kingdom. In 1296 the French made a descent upon this place, and committed great depredations in the neighbouring country. It witnessed the landing of Charles II. on his restoration to the British throne, May 27, 1660, and the embarkation of Louis XVIII., April 24, 1814, on the restoration of the Bourbons in France. Dover now

consists of an old and a new town; the former is the seat of most of the trade, and has narrow and irregular streets. The new portion is built with more taste, and contains a number of good houses, chiefly occupied by summer visitors. The importance of the town is principally owing to its position as a channel of communication between England and the continent. It was formerly the chief port of embarkation, but has been partially superseded in that respect by Folkestone. The Southeastern and Dover railway, which enters the town through a tunnel cut in the cliffs, connects it with the cities of Great Britain, and it has continual steamboat intercourse with Calais and Boulogne. Large sums of money have been spent at various times upon its harbor, which consists of 3 basins, the outer one enclosed between 2 piers 150 feet apart, but the entrance is unfortunately obstructed by a movable shingle bar. It has been determined to construct here a harbor of refuge, and the sum of £2,500,000 has been appropriated for the erection of immense jetties to reach far out into the sea. The submarine telegraph between England and the continent extends across the channel from Dover to Calais; it was completed in Oct. 1851. In the vicinity of the town, abutting on the sea, stands the remarkable chalk cliff called Shakespeare's or Hay cliff, described in "King Lear;" it is 350 feet high and almost perpendicular. In May, 1847, a huge mass of this cliff, 254 feet in height, 15 feet thick, and estimated to contain 48,000 tons of chalk, scaled off and fell to the base. Another mass of 10,000 cubic yards fell soon after. There are a number of ship yards on the coast, and many of the inhabitants are employed in sail and rope making. The registered shipping of the port in 1856 was 55 vessels of 3,553 tons; the entrances were 473 sailing vessels, tonnage 43,487, and 21 steam vessels, tonnage 2,679; clearances, 121 sailing vessels, tonnage 5,112, and 5 steam vessels, tonnage 663. The coasting trade of Dover is flourishing, and its fisheries are extensive and profitable. It imports from France large quantities of eggs, fruit, and other rural produce. There are several large paper mills in the neighborhood. The principal buildings in the town are 2 hospitals, 2 parish churches, a number of chapels, a synagogue, the custom house, town hall and gaol, workhouse, assembly rooms, theatre, museum, baths, news rooms, bonding warehouses, and many good hotels. Dover is the seat of government and principal station of the cinque ports, and returns 2 members to the house of commons.

DOVER, Strait of (Fr. *Pas de Calais;* anc. *Fretum Gallicum*), a strait connecting the English channel with the German ocean, and separating England from France. It extends from Dungeness and Cape Gris Nez N. E. to the S. Foreland and Calais; length, 22 m.; breadth at Dover, where it is narrowest, 21 m.

DOVER'S POWDERS, a preparation of ipecacuanha and opium, each a drachm, and of sulphate of potassa an ounce, rubbed together into a very fine powder. Though called by the name of Dr. Dover, it differs from that originally recommended by him, which contained nitrate of potash and licorice in addition to the ingredients named. It is a medicine admirably adapted for promoting perspiration, and possesses at the same time the properties of an anodyne. It is given, after depletion, in cases requiring profuse diaphoresis, and is particularly used in dysentery, diarrhœa, and affections of the liver and of the bowels, sometimes combined with small quantities of calomel.

DOVREFIELD, Dovrefjeld, or Dofrines (Norw. *Daavrefjeld*), a name sometimes given to the whole system of the Scandinavian Alps, which extend from Cape Lindesnaes on the Cattegat, along the dividing line between Sweden and Norway, to Cape Sviatoi, at the W. entrance to the White sea. The Dovrefield mountains, however, properly consist only of the central part of this range, extending in an E. N. E. direction from the valley of Lessöe, where the Langfield range or S. portion terminates, to the Syltfjället, where the chain of Kiölen or Kiöel begins. They are composed mostly of gneiss and micaceous schist. The principal peak is the Skagstols-tind, a snow-capped mountain having an altitude of 8,390 feet. It is the highest summit in the Scandinavian peninsula. There are 4 passes across this range, along which at intervals of 10 m. there are houses for the reception of travellers. The most frequented of these roads leads from Christiania to Trondhjem, and passes along the E. declivity of the peak of Sneehaettan. It reaches in some places an altitude of 4,200 feet. The Dovrefield mountains derive their name from *Daavre*, a small village of Norway, and *field* or *fjeld*, a mountain ridge.

DOW, Lorenzo, an American preacher, born in Coventry, Conn., Oct. 16, 1777, died in Georgetown, D. C., Feb. 2, 1834. When about 14 years of age he began to be agitated by religious speculations, had frequent dreams and visions, and was so troubled by his meditations upon the "doctrine of unconditional reprobation and particular election," that on one occasion he was on the point of putting an end to his life. Finally he adopted the doctrines of the Methodists, and in the spring of 1796, after many mental struggles and against the wishes of his family, became an itinerant preacher of that persuasion. His youth and eccentricity of character for a long time prevented his recognition by the conferences of the Methodist church, and he was at one period even prompted to renounce the name of Methodist. He finally received a regular license to preach, and, in spite of contumely and rebuffs, frequently from members of his own sect, and ceaseless hardships and dangers of all kinds, persevered for nearly 40 years, with an enthusiasm which never relaxed, and often with astonishing effect. In the course of his ministry he travelled over many parts of the United States and Canada, and in 1799 and again in 1805 visited England and Ireland,

where his peculiar eloquence attracted much attention and on several occasions subjected him to persecution. His wife, Peggy Dow, to whom he was married in 1804, was a woman of character and qualities very similar to his own, and accompanied him fearlessly in all his peregrinations. Dow's eccentricity of manner and dress for a long time excited a prejudice against him, and in many parts of the country he was familiarly known as "crazy Dow." In person he was awkward and ungainly, his voice was harsh, and his delivery not such as would impress a cultivated mind. But to the class whom he most frequently addressed, his simple fervor, though coupled with illiterate phraseology, supplied the place of eloquence, and he seldom failed of having attentive and even enthusiastic hearers. Many anecdotes are related of his courageous bearing, when threatened with violence by lawless men. His journal, containing the history of his life to his 40th year, together with some of his miscellaneous writings, and a short autobiography of Peggy Dow, was published in New York in 1856.

DOWER (law Lat. *doarium*, or *douarium;* Fr. *douaire*), the estate which the wife has by operation of law in the property of her deceased husband. Strictly it applies only to what the law gives her independent of any act of the husband, and which, in fact, it is not in his power to bar. A marriage portion, therefore, whether given with the wife or secured to her use, and whether so given or secured by the father or other relative, or by the husband himself, is not dower; and yet the term by which such marriage portion was designated in the Roman law (*dos*) was used by Bracton and other English writers for the right of the widow in the lands of her deceased husband given to her by the common law, as well as the endowment in contemplation of marriage, which last was also called *donatio ante nuptias*. The English word dower expressed the former, and also the donation before marriage, which was in two modes, viz.: *ad ostium ecclesiæ*, and *ex assensu patris*. Both of these were made at the porch of the church, after affiance and before marriage; in the one, the husband endowed the wife of lands of which he was himself seized; in the other, with consent of his father, he endowed her of lands belonging to his father; and it was usual to specify the particular lands intended. Endowment at the church door was the common mode of providing for the wife in the time of Bracton, and no other mode could be substituted, as by will or any other conveyance; the object of which was to prevent fraud: *Non enim valent facta in lecto mortali, nec in camera, aut alibi ubi clandestina fuerunt conjugia*. The feudal restriction against alienation of lands was, however, extended to dower, and the husband was not allowed to endow the wife *ad ostium ecclesiæ* of more than a third part of his lands. This gave rise to the common law rule which has ever since prevailed. In the absence of such dotation, or in case of the omission to specify the particular lands, it was prescribed that the wife should be entitled to one-third of the lands of the husband for life if she survived him, which was called *dos rationabilis*. It was at first limited to the lands which the husband had at the time of the dotation, unless he specially charged his future acquisitions; and in case he had no lands, or not sufficient, he was permitted to endow his wife of personal property, which was held to be a bar against any claim to dower of lands thereafter acquired. But in Magna Charta it was provided that the wife should have for dower the third part of all the lands which the husband had held during his lifetime, unless she had been endowed with less *ad ostium ecclesiæ*. In the reign of Henry IV. it was denied that the wife could be endowed of her husband's goods and chattels; and Littleton, who wrote in the reign of Edward IV., asserted that she could be endowed *ad ostium ecclesiæ* of more than a third part of the lands, and that she had the election after the husband's death to accept it or to take her dower at common law. In consequence of this uncertainty, that mode of endowment fell into disuse, but was never abolished by law until recently by act 3 and 4 William IV., c. 105 (1833). Dower at common law is different from the dotation of other countries, in being limited wholly to lands, and to such only as the husband holds in fee. By the civil law the *donatio ante nuptias* (or, as Justinian called it, *propter nuptias*) was all the provision made for the wife. It might consist of either lands or personal property; but though it went into the possession of the husband, it could not, if it consisted of lands, be alienated by him even with the consent of the wife, for which the reason given is the fragility of the female sex (*ne sexus muliebris fragilitas in perniciem substantiæ earum convertatur*). Upon the death of the husband, or dissolution of the marriage otherwise, the wife only took what had been given with her on the marriage, or of which a donation had been made during the marriage. Of the other property of the husband she could take nothing either as widow or heir.—In France, the two modes of providing for the wife are designated by the discriminative terms *dot* and *douaire;* the former of which is defined to be that which the wife brings in marriage (*ce que la femme apporte en mariage*); the latter is the right which the wife has, by custom or matrimonial contract, to a certain portion of the estate of the husband upon his death (*la jouissance que la coutume ou les conventions matrimoniales accordent d'une certaine portion des immeubles du mari à la femme qui lui survit*). The origin of *douaire* was that in some provinces of France, called *France coutumière*, women were not endowed on marriage (*n'avoient pas de dot de leur parens*); and hence grew up the custom that the husband at his death should leave something for the support of the wife. What was so left was called either *dot* or *douaire*, the wife being said to be *douée* or *dotée*. But as it was intended for her support merely, it was provided that after

her death it should go to the children of the husband if he left any. Philip Augustus fixed the dower of the wife at one-half of the goods which the husband had at the marriage. Henry II. of England established in his French provinces a rule that dower should be one-third, and this difference continued to exist on the opposite sides of the Loire, until the customary law was swept away by the legislation which succeeded the revolution of 1789. By the present law of France married persons may, by stipulation made before marriage, become subject to the law of community, or to the law of dowry. If the former, it brings into common stock all the movables of which the parties are possessed at the time of marriage, and of immovables which shall be acquired during marriage. Dower (*la dot*) is what the wife brings to the husband in marriage, and it may be either by donation from another or by a settlement of the wife upon herself (*tout ce que la femme se constitue ou qui lui est donné en contrat de mariage est dotal*), and it may extend to all the present or future property of the wife, but cannot be constituted or augmented during marriage. The parties may stipulate for a community of future acquisitions only. The husband has the management of dotal property, but is accountable as a usufructuary, and in case it be put in peril, the wife may obtain a separation of goods.—The English law of dower has recently undergone very great changes. By stat. 3 and 4 William IV., c. 105, the widow is not entitled to dower of lands which the husband has disposed of in his lifetime, or by will. All charges by will, and all debts and encumbrances to which the estate of the husband is subject, take priority of dower; and dower is made subject to any restrictions which the husband may impose by will. But on the other hand, the wife is entitled to equitable dower of any beneficial interest of the husband which shall amount to an estate of inheritance in possession, except joint tenancy; and no gift of personal property by the husband can invalidate the right to dower, unless expressly so declared by will. This modification of the law of dower has probably grown out of the general custom prevailing in England among land proprietors of making marriage settlements. In cases where this is omitted, the wife still has some provision under the statute of distribution (29 Charles II.), which gives her one-third of the personal estate of the husband when he dies intestate, not for life merely, but absolutely.—In the United States, the general rule prevails of allowing to the widow an estate for life in one-third of all the lands of which the husband was seized in fee. The rule, however, varies in different states in two particulars. In the state of New York, and most other states, dower is a charge upon all the lands of which the husband was seized at any time during the marriage, except such as she has released by joining in the conveyance thereof by the husband. In some of the states, as Vermont, Connecticut, Tennessee, North Carolina, and Georgia, it is limited to the lands of which the husband was seized at the time of his death; but the husband is not allowed to bar dower by will, nor by a voluntary conveyance, in which any benefit is reserved to himself. Again, in Pennsylvania, Tennessee, and Missouri, dower does not attach to lands sold under judicial process, nor to lands sold under a mortgage executed by the husband alone. The rule is general, perhaps universal, that the wife takes one-third of the personal estate upon the death of the husband, in accordance with the English statute of distribution.

DOWLER, Bennet, an American physician and physiologist, born in Ohio co., Va., April 16, 1797. He was educated at the university of Maryland, where in 1827 he received the degree of doctor of medicine. During the last 23 years he has practised his profession in New Orleans, and since March, 1854, has been the editor of the "New Orleans Medical and Surgical Journal." From an early period in his career experiments upon the human body, immediately or very soon after death, occupied a large share of his attention, and the results of his investigations, comprising some important discoveries with regard to contractility, calorification, capillary circulation, &c., were given to the world in a series of essays in 1843–'4. Since that time these and other original experiments have been extended, generalized, and analyzed by him. With one exception he has found in the course of his experiments no fact invalidating the fundamental laws which he announced in his first publications relative to *post mortem* contractility of the muscular system. He had prematurely assumed, early in his researches, in accordance with the prevailing theory, that the death rigidity, or *rigor mortis*, is antagonistic to, or incompatible with, the coexistence of muscular contraction; but he soon found instances which led him to maintain that the contractile function exists in all bodies immediately after death, although in some it is scarcely appreciable, while in others it is absent or feeble at first, but gradually increases. In all it is intermittent, and may be economized by proper management, or overtasked and exhausted, or even destroyed by a severe blow. He was consequently led to the conclusion that this force is inherent in the muscular tissue, and in every portion of it, being wholly independent of the brain, spinal cord, and nerves. During the last 18 years Dr. Dowler has shown by experiments on hundreds of human bodies that the capillary circulation is often active for some minutes, and even for hours, after the respiration and the action of the heart have ceased, and occasionally after the removal of this organ; and that in the same cadaver a high degree of calorification, together with active capillary and chylous circulations, may continue simultaneously for several hours. His researches on animal heat, in health, in disease, and after death, which have from time to time been published

in medical journals, have led to important discoveries, particularly with reference to *post mortem* calorification, which his experiments have shown will, after death from fever, cholera, or sun-stroke, &c., rise in some cases much higher than its antecedent maximum during the progress of the disease. From these experimental researches, as well as from a rational interpretation of the respiratory action of the lungs, either in their natural, diseased, obstructed, or disorganized conditions, Dr. Dowler has been led to reject the long received theory which ascribes animal heat to the lungs, as the sole heating apparatus of the animal economy. He maintains that the chemical history of respiration may be interpreted either as a refrigeratory or heat equalizing process, and that while the absorption of oxygen during respiration may generate heat, on the other hand the parting of carbonic acid gas and aqueous vaporization from the lungs, together with the incessant respiration of the air, almost always much cooler than the body, must refrigerate the animal economy; that for all that has been proved to the contrary, oxidation and deoxidation, repair and waste, composition and decomposition, inhalation and exhalation, are mutually compensating or equiponderant in the regulation of animal heat; and that, while it may be plausibly assumed that nearly the whole series of organs and organic functions, especially those of nutrition, contribute directly or indirectly to the origin and distribution of animal heat during life, *post mortem* calorification might to some extent be accounted for by assuming that respiration is not a heating, but a refrigeratory process, which, ceasing with apparent death, ceases to liberate the free caloric of the economy; whence the calorifacient function, not being in many instances extinguished with the respiration, persists, and for a long time accumulates faster than it can be radiated into the surrounding media. He has not, however, been able to trace a necessary connection, antecedence, or parallelism between *post mortem* calorification and muscular contractility, the development, degree, and duration of which may or may not coincide. In March, 1845, Dr. Dowler commenced a series of experiments in comparative physiology on the great saurian or alligator of Louisiana, which he regarded as much better for the purpose than any of the cold-blooded animals usually selected for vivisection. From these experiments, which embrace a period of 10 years, he has ascertained that after decapitation the head, and more especially the trunk, afford unequivocal evidences of possessing the faculties of sensation and volition for hours after a complete division of the animal. The headless trunk, deprived of all the senses but that of touch, perceived, felt, willed, and acted with unerring intelligence in removing or avoiding an irritant, such as an ignited match or bit of paper; when even a simple touch or a positive irritant was applied laterally, the body curved or receded in a contrary direction, while the most convenient limb was also directed to the exact place where the foreign body impinged, in order to remove it, if possible. After as well as before decapitation, after complete evisceration, and after the subdivision of the spine and its cord in 2 or 3 places, each section mutually and simultaneously perceived or felt in common the presence or contact of a pain-producing agent. In some instances Dr. Dowler observed that the separated head could see a body, like the finger, purposely directed close to the eye, as was shown by the violent opening of the mouth, as if to bite, and by the head jumping several feet from the operating table to the floor. The vivisection of the spinal cord satisfied him also that neither root of the spinal marrow is the exclusive seat of sensation or of motion, and that motion as well as sensory phenomena may be excited by irritation of either root; a result directly opposed to the celebrated theory of Sir Charles Bell on the functions of these roots. The vivisection of the inferior animals (hitherto the basis of experimental physiology), as well as the pathological, anatomical, and experimental phenomena observed in man, has therefore led Dr. Dowler to the following conclusions: that the functions and structures of the nervous system constitute a unity altogether inconsistent with the anatomical assumption of 4 distinct and separate sets of nerves, and a corresponding fourfold set of functions; that there is no anatomical or other proof that one set of nerves transmits impressions to, and a separate set from, a sensorial spot somewhere in the brain, nor that the nerves themselves are simple conductors and wholly insensible; that the 2 separate sets of nerves usually assigned to what is called the excito-motory action of the spinal cord are wholly hypothetical; that instead of 4 travelling impressions there is but one, the primary or sensiferous impression, which is simultaneously cognized upon the periphery as well as in the centre, and not solely by an unknown spot in the brain through the intermedium of a secondarily transmitted impression, being intuitively felt where it really is; and that sensuous cognition or sensation is immediate, intuitive, and not representative, nor the result of transmitted secondary impressions, but a directly felt relation, *ab initio*, between an object and a sentient subject, and not one between a mere secondary representation, idea, or transmitted impression of an object.—The assiduous devotion of Dr. Dowler to researches connected with medical and physiological science has won for him a wide reputation as an experimenter, an anatomist, and a pathologist.

DOWLETABAD, Dowlatabad, Dowlutabad, Douletabad, or Deoghir (the fortunate city), a town and fortress of Hyderabad, in the Nizam's territory, Hindostan, about 10 m. N. W. from Aurungabad. The fortress is situated on a hill about 500 feet in height, about 150 feet of which rises nearly perpendicularly, like a wall. The entrance is by a passage cut

through the rock. Notwithstanding its natural strength, the fortress has been several times taken, and has fallen under the dominion of various masters. Near the town are the remarkable cave temples of Ellora.

DOWN, a maritime co. in the N. E. part of Ireland, province of Ulster; greatest length, N. E. to S. W., 51 m.; greatest breadth, 38 m.; area, 956 sq. m.; pop. in 1851, 328,883. Near the middle of the county is a group of hills, and in its S. W. part are the Mourne mountains, some of whose summits are among the highest peaks in Ireland; but with these exceptions the surface of the county is for the most part tolerably even. There are several rivers and numerous lakes, both abounding in fish, but insignificant in size. Lough Strangford in the E. part of the county, though almost surrounded by land, is yet only a large inlet of the sea, with which it communicates by a channel navigable for large vessels. The county contains many mineral springs, and is one of the best cultivated of all the counties of Ireland, producing large crops of grain, peas, beans, potatoes, turnips, &c. The total extent of land under crops in 1855 was 310,424 acres. The raising of cattle is carried on mostly for dairy purposes, large quantities of butter being annually made and exported; and hogs are reared in great numbers. There are extensive quarries of limestone, sandstone, and slate; and granite, coal, and chalk also occur. The most important manufacture is that of linen, though there are also cotton and woollen mills. The climate is healthy and somewhat cold, and the people generally are in a better condition than those of most Irish counties. The fishery occupies many of the inhabitants, though not to an extent commensurate with the facilities for it. Some interesting remains of antiquity are found, and there are also ruins of abbeys and castles of the middle ages. Four members are returned to the house of commons, two for the county, and one each for the towns of Downpatrick and Newry.

DOWNES, John, a commodore in the U. S. navy, born in Canton, Norfolk co., Mass., in 1786, died in Charlestown, Mass., Aug. 11, 1855. He entered the navy as a midshipman in June, 1802, and his first service was in the frigate New York during the war with Tripoli. In May, 1803, he distinguished himself in a boat attack upon some Tripolitan feluccas, which had been chased into the port of Old Tripoli. In March, 1807, Downes was promoted to a lieutenancy, and during the war of 1812 served as executive officer of the frigate Essex, Capt. Porter, during her celebrated cruise in the Pacific ocean. Among the numerous prizes of the Essex was the whale ship Georgiana, which Capt. Porter fitted as a cruiser, with 16 guns, named the Essex Junior, and placed under the command of Lieut. Downes with a crew of 41 men. Finally, after the capture of the Essex at Valparaiso by the British frigate Phœbe and sloop Cherub, the Essex Junior was converted into a cartel for the purpose of carrying Capt. Porter and his surviving officers and men to the United States. In June, 1813, Lieut. Downes was promoted to the rank of master commandant, and in March, 1815, he commanded the brig Epervier of 18 guns in the squadron employed against Algiers in that year, under Commodore Stephen Decatur. On June 17, 1815, the Epervier assisted in the capture of the Algerine frigate Mashouda off Cape de Gatt. Two days afterward the Epervier and 3 of the smaller vessels of the squadron captured the Algerine brig of war Estido, 22 guns and 180 men, which had been chased into shoal water off Cape Palos. After the conclusion of the treaty of peace with Algiers, Commodore Decatur transferred Downes to his own ship, the Guerriere, while the Epervier, which was sent to the United States with the treaty, was never afterward heard from; it was supposed that she foundered in a heavy gale near the Western islands. In March, 1817, he was promoted to a captaincy, and from 1819 to 1821 commanded the Macedonian frigate of 50 guns in the Pacific. In 1828–'9 he commanded the frigate Java in the Mediterranean, and from 1832 to 1834 the squadron in the Pacific ocean. On his way to his station he anchored, Feb. 5, 1832, off Quallah Batoo, on the coast of Sumatra, where an outrage had been committed on an American vessel. His ship, the Potomac of 50 guns, was disguised as a merchantman. The town was supposed to contain not less than 500 fighting men, and was defended by 5 forts, owned and commanded by different rajahs or chiefs. The commodore had obtained tolerably correct information of their positions, as well as of the general topography of the place, but nevertheless deemed it advisable to make an actual reconnoissance if possible. An attempt was made to land a party of officers for this purpose, in citizens' dress, but as the boat (rowed by officers disguised as seamen) approached the landing, such hostile demonstrations were made by the natives that she was recalled. Preparations for an attack were now made, and about 2 o'clock in the morning of Feb. 6, about 150 officers, seamen, and marines were landed under the command of Lieut. Irvine Shubrick, the 1st lieutenant of the ship. This force was organized in divisions, the marines under Lieuts. Edson and Terrett, the seamen in 4 divisions commanded by Lieuts. Pinkham, Hoff, Ingersoll, and Sailing-master Totten. To each division a particular duty was assigned, and although the surprise was not quite perfect, the result was entirely successful. After 2½ hours of severe fighting, the town was nearly reduced to ashes, many of the natives were killed, and 4 of the forts were captured and blown up. This being accomplished, the expedition reëmbarked in perfect order, and returned to the ship with a loss of 13 killed and wounded. A flag of truce was immediately sent off from the town, and peace sued for, which was granted. Several of the rajahs from the towns in the vicinity sent deputations, declaring their friendly disposition to the Americans, to which the commander gave corresponding as-

surances, and soon after sailed for the Pacific. Our commerce at Quallah Batoo has never since been molested. The sea service of Com. Downes terminated with this cruise. From 1837 to 1842, and from 1850 to 1852, he commanded the navy yard at Boston.

DOWNING, Andrew Jackson, an American landscape gardener, born in Newburg, N. Y., Oct. 30, 1815, drowned in the Hudson river, near Yonkers, July 28, 1852. From an early age his tastes were directed to horticulture, botany, and the natural sciences, which the occupation of his father, who carried on business as a nurseryman in the vicinity of Newburg, gave him many opportunities to cultivate. His school education was acquired chiefly at an academy in the neighboring town of Montgomery, from which he returned home at the age of 16 to assist an elder brother who had succeeded his father in the management of the nursery. At school he was a thoughtful, reserved boy, made few friendships, and seldom joined in boyish pastimes; but he was always a diligent reader and a close observer, and now endeavored to compensate for what he considered a premature removal from his studies by a course of self-instruction in his favorite sciences. In the intervals of his labors in the garden he read treatises on landscape gardening, botany, the culture of fruits and flowers, and in general every thing pertaining to the economy of rural life; and found time also to make himself familiar with poetry, art, and elegant literature. At 20 years of age he determined to become a rural architect, and with a mind richly stored with knowledge suitable to his vocation, he began to visit the neighboring estates on the Hudson river, to enlarge his experience and confirm his theories of art in landscape gardening. Three years later he was married to Miss Caroline De Wint, and almost immediately afterward commenced the erection on his little paternal estate of an elegant mansion, which, with its tastefully arranged grounds, afforded the first practical illustration of the builder's conception of an American rural home. He had previously written a few fugitive pieces for the newspapers, but his career as an author properly commences with the publication in 1841 of his "Treatise on the Theory and Practice of Landscape Gardening." As a pioneer work of its class in this country, it necessarily attracted attention, and the author's extensive information, correct ideas of taste, and appreciation of the conditions of rural architecture in America, gave it immediate popularity and a position as a standard authority. In England it was highly commended by such competent judges as Loudon and Dr. Lindley, the latter of whom said that he "knew of no work in which the fundamental principles of this profession were so well or so concisely expressed." The "Cottage Residences," which followed in the succeeding year, was received with equal favor; and until his death Downing continued to be the chief American authority in rural art. The appreciation in which he was regarded abroad was evinced by his election as corresponding member of many of the chief horticultural societies of Europe. In 1845 appeared simultaneously in London and New York his "Fruits and Fruit Trees of America," of which more than 14 editions have been published; and in 1846 he became the editor of the "Horticulturist," a monthly magazine published in Albany, for which he wrote an essay every month until the close of his life. In 1849 he wrote "Additional Notes and Hints to persons about building in this country" for an American reprint of Wightwick's "Hints to Young Architects," and in 1850 published his "Architecture for Country Houses." His remaining work was an edition of Mrs. Loudon's "Gardening for Ladies." The summer of 1850 he passed in England, chiefly among the great country seats, of which he wrote some genial descriptions. On his return to America, having determined to devote himself exclusively to architecture and building, he received many private commissions, and was intrusted by President Fillmore in 1851 with the laying out of the public grounds in the city of Washington, in the vicinity of the capitol, the president's house, and the Smithsonian institution. In the midst of these labors he took passage at Newburg on July 28, 1852, in the steamboat Henry Clay, for New York. When near Yonkers, about 20 miles above New York, the Henry Clay, which had been racing with a rival steamboat, was discovered to be on fire, and was immediately steered for the shore. In the confusion of the moment Mr. Downing was separated from his wife, and when the heat of the conflagration had compelled him with many others to jump overboard, he was seen for the last time struggling in the water, with several persons clinging to him. His body was subsequently recovered and sent to Newburg for interment. A memoir of him by George W. Curtis, and a "Letter to his Friends," by Miss Bremer, who had been his guest during her visit to America, were prefixed to a collection of his contributions to the "Horticulturist," published in 1854, under the title of "Rural Essays." The labors of Mr. Downing gave a great impulse to the dissemination of correct taste in rural architecture among the American people, and of a love for rural life.

DOWNS, a term applied in England to hills of shifting sand along the coast; also called Dunes, which see. Barren tracts of hilly land used for sheep pasture are also called downs. A portion of the English channel, affording excellent anchorage, and much used by the British navy, bears the same name.

DOWSE, Thomas, an American mechanic, who has obtained considerable celebrity as a lover of books and the collector of a valuable library, born in Charlestown, Mass., Dec. 28, 1772, died in Cambridgeport, Nov. 4, 1856. He has sometimes been called "the literary leather dresser." His father, Eleazer Dowse, was a leather dresser, and was driven with his

family from Charlestown on June 17, 1775, his house being one of those destroyed by the conflagration of that day. After a short time passed at Holliston, he established himself at Sherborn, a small town in Middlesex co., the original seat of the family, and there resumed his occupation as a leather dresser. At the age of 6, Thomas was severely injured by a fall from a tree; and a rheumatic fever setting in before he had recovered from the effects of this accident, a lameness resulted which continued, with frequent attacks of severe pain, through life. At the proper age, Thomas began to work with his father, at his trade and on the farm; forming at the same time a taste for reading, which he indulged with so much eagerness that, by the age of 18, he had read all the books he could procure in Sherborn. All his little earnings were expended in the purchase of books. He had no education but what could be obtained at the town school. He continued to live at home as an apprentice to his father till he had attained his majority. He was then seized with a desire to visit foreign countries. A neighbor of his father's, who commanded a vessel that traded from Norfolk in Virginia to London, offered him a free passage; he was, however, to reach Norfolk at his own expense. Too poor to accompany the captain by land, he engaged a passage in a coasting vessel from Boston. Head winds prevented the departure of the coaster till the vessel had sailed from Norfolk, and thus Thomas Dowse lost the opportunity of visiting foreign countries. Another never presented itself. He immediately sought employment in the business in which he had been brought up, and entered the service of Mr. Wait, a leather dresser and wool puller at Roxbury, Mass, at $12 a month wages. His pay was afterward raised to $25. He remained in this employ 10 years. He once informed a friend that at the age of 28 his highest income was $25 a month; that he had never paid $5 for conveyance from one place to another, never owned a pair of boots, and was then the possessor of several hundred volumes of good books well bound. In 1803 he set up in business at Cambridgeport, with the assistance of Mr. Wait, who advanced the capital and shared the profits. This partnership was dissolved at the end of the year; after which Mr. Dowse carried on the business of a leather dresser, wool puller, and glover, at first with a succession of partners, and afterward alone, till he was far advanced in life. His business was successful, and the articles manufactured by him enjoyed the reputation of being the best of their kind in the market. In 1814 he erected a large and commodious dwelling-house and shop in Cambridgeport, and laid out 2 or 3 acres as a garden; and here he lived unmarried the rest of his days. From the earliest period he devoted a large part of his income to the purchase of books. The working hours of the day were devoted to his shop or business connected with it; but the early morning and the evening hours were employed in reading. He thus acquired an intelligent knowledge of the contents of his steadily increasing library. Having formed a taste, not only for good books but for handsome editions, in which the American press was then greatly deficient, he was accustomed to import them directly from London. About the year 1820 his agent in England sent him the prospectus of a lottery for the disposal of the sets of a costly collection of engravings of the most famous works of the old masters, and of the water-color copies made from the originals, for the purposes of this publication. Mr. Dowse bought 3 tickets in this lottery, and drew 2 prizes, one prize consisting of 2 sets of the engravings, colored and uncolored; the other prize being ⅓ of the water-color copies framed, 52 in number. He thus became possessed of a large collection of admirable copies of some of the most celebrated paintings in England. In the judgment of Mr. Washington Allston, it afforded ampler means for the study of art than were elsewhere to be found at that time in the United States. The paintings were advantageously arranged in rooms adjoining Mr. Dowse's library, and formed with it an attraction of steadily increasing interest to men of letters and taste resident in the neighborhood, and to strangers. Mr. Dowse's bodily infirmity unfitted him for much active intercourse with society, and his disposition naturally inclined him to retirement and solitary occupation. He abstained from public life in all its forms, and though a diligent reader, committed nothing to writing. He continued to work at his trade till after he was 70 years of age; but for the last 10 years of his life, though his shop remained open in the lower story of his dwelling, the business was conducted by persons in his employ. Of the eminent men whom the country has produced, Franklin was one of the special objects of Mr. Dowse's admiration. Toward the close of his life he expressed this sentiment by the erection, at his own expense, of a substantial granite obelisk at Mount Auburn, by the side of his own tomb. With the exception of the statue of Franklin presented by Mr. Bingham to the public library at Philadelphia, and the urn in Franklin place, Boston, which is rather an ornamental than a commemorative work, the obelisk erected by Mr. Dowse is believed to have been the first monument dedicated to the memory of Franklin in the United States. As Mr. Dowse was childless, the destination of his library after his decease was a matter of some curiosity among those acquainted with its value. A few months before his death he formed the resolution to present it to the Massachusetts historical society; and on July 30, 1856, the formal transfer was made. The library, however, was left by the society in the possession of M. Dowse during the brief remainder of his life. It consisted of about 5,000 volumes of a miscellaneous character, generally in good, often in elegant bindings, and of the best editions. It is almost exclusively an English library, though contain-

ing translations of the principal authors in the ancient languages, and the cultivated languages of modern Europe. It is estimated to have cost Mr. Dowse $40,000 without interest. After his death the library was deposited in the historical society's building, in an inner room fitted up for the purpose, and arranged in tasteful cabinets at a cost of $3,000 advanced by his executors, in addition to a sum of $10,000 also given by them as a permanent fund for the conservation and care of the library. Mr. Dowse in his will made provision for his relatives to the extent of $25,000. The residue of his property, amounting to about $40,000, was placed at the disposal of his executors, to be by them appropriated to literary, scientific, or charitable purposes. The collection of water-colors was given by them to the Boston Athenæum, where it is displayed in an apartment exclusively devoted to that purpose. Handsome donations have been made by the executors to the botanic garden of the university at Cambridge, and to other meritorious public objects in Cambridge and Boston. The Dowse high school has been founded by them at Sherborn, where he passed his youth and learned his trade; and the Dowse institute established at Cambridgeport, in the immediate vicinity of his residence. A commemorative discourse was delivered by Mr. Edward Everett, at the opening of the Dowse institute, Dec. 7, 1858, and before the Massachusetts historical society on Dec. 9. A fine portrait of Mr. Dowse was painted a short time before his decease by Wight of Boston, at the request of the society, and now adorns the room in which his library is deposited.

DOXOLOGY (Gr. δοξα, glory, and λεγω, to ascribe), in general, a prayer to celebrate the grandeur and majesty of God. In the Roman Catholic church it is applied particularly to the angelic hymn or canticle of praise which is sung in celebrating the mass, and is otherwise called the *Gloria in excelsis*. This is also styled the greater doxology, to distinguish it from the lesser, or *Gloria Patri*, which is usually sung after the chanting or recitation of a psalm. Both doxologies are traced to the earliest periods of the church, and though slightly and temporarily modified during the prevalence of some heresies, have not been permanently changed. They both have a place in the liturgy of the Anglican church, and are of common use in the service of other branches of Protestantism.

DOYLE, Richard, an English humorous artist, born in London in 1826. From his father, Mr. John Doyle, an able political caricaturist, he inherited a taste for humorous illustration, and a few years after the establishment of "Punch" became known to the public by his designs published in that paper. His political caricatures are singularly free from direct personalities or the appearance of malice, but his humorous illustrations of London life afford the best examples of his harmless wit and graceful fancy. The series entitled "Manners and Customs of y^e^ Englyshe," though ostensibly caricatures, are in fact sketches of the every-day life of the people, and for liveliness of invention and various technical merits may be regarded as unique performances. The "Continental Tour of Messrs. Brown, Jones, and Robinson," perhaps the most popular of his works, is in like manner a somewhat exaggerated view of the lights and shadows of travel on the continent. In 1850 Mr. Doyle, taking umbrage at the severe attacks of "Punch" upon the Roman Catholic hierarchy, severed his connection with that paper, since which time he has employed his pencil chiefly in illustrating books of fairy tales, and similar publications, including the "Fairy Ring," "Fairy Tales from all Nations," Leigh Hunt's "Jar of Honey," Ruskin's "King of the Golden River," &c. He fails in attempting to depict the merely pleasaic or the sentimental, and his illustrations to Thackeray's "Newcomes" are comparatively feeble.

DRACHENFELS (Dragon's Rock), the most celebrated of the Siebengebirge range, or "seven hills" (though their number is really more than 7), on the right bank of the Rhine, near Bonn. The ascent of the mountain, which is 1,056 feet high, is fatiguing from its steepness, but amply rewards the traveller by the majestic beauty of the scenery of the river and valley beneath, and of the adjoining panorama of ruin-clad mountains. Upon the summit of the Drachenfels are the ruins of a castle of the 12th century, a monument erected in 1814 by the Siebengebirge militia to their gallant leader Genger, who died on the battle field, and another in August, 1858, in commemoration of the German war of independence. Here also is a famous quarry which furnished stone for the cathedral of Cologne, and hence called *Dombruch* (dome or cathedral quarry). The beauty of this far-famed mountain has been a fruitful theme with poets of every land, but to English readers it is familiar chiefly from the well-known verses of Byron. Its name is explained by a tradition of a dragon which inhabited a cavern in its sides, and was slain by Siegfried, the hero of the Nibelungen lay.

DRACHMA, a measure both of weight and value among the ancient Greeks. In either case it was composed of 6 *oboli*, and was the $\frac{1}{100}$ part of the *mina*, and the $\frac{6}{10000}$ part of the Attic talent. The drachma was the principal silver coin of the Greeks, and its value was from 15.20 to 17.05 cents. The drachma or drachm mentioned by Jewish writers was the Greek coin which became current among the Jews in the latest period of their national existence.

DRACO, the author of the first written code of laws at Athens, which he is supposed to have published in the 4th year of the 39th Olympiad, 621 B. C. He was of distinguished birth and virtue, honored for his severe manners and his large experience in public affairs; and the people of Athens, a prey to anarchy, besought him to give them a code of laws. Like all the other legislative systems of antiquity, the system which he proposed linked together civil and

moral duties. He took the citizen at the moment of his birth, prescribed the manner in which he should be nourished and educated, followed him with directions through the different epochs of life, and flattered himself that he should make men free and virtuous. The penalty of death was to be inflicted for almost every crime, for homicide and idleness, for sacrilege and the stealing of garden herbs. The slightest offence, he said, deserved death, and he knew no punishment more severe for the greatest. He even carried his severity to a fantastic extreme, ordering punishment to be inflicted upon inanimate things, as for instance on a statue whose fall had injured a man. So violent a code could not last, and within 30 years Athens was again in anarchy. Recourse was then had to Solon, whose wisdom and moderation gave to the Athenians, not, as he himself said, the best laws, but the best that they were able to support. Draco died at the culmination of his glory upon the isle of Ægina. As he entered the theatre he received the acclamations of the people, and was stifled amid the mass of caps, robes, and cloaks, which they in accordance with their custom threw upon him as a mark of honor.

DRACUT, a post village and township of Middlesex co., Mass., on the N. bank of Merrimack river, opposite Lowell, with which it is connected by 2 bridges, 28 m. N. W. from Boston, and 16 N. E. from Concord; pop. of the township in 1850, 3,450; in 1855, 1,966, a portion of it having been annexed to Lowell in 1851. It borders on New Hampshire, and is traversed by Beaver river, which supplies it with water power. It is mainly an agricultural town, but in 1855 had 1 cotton mill manufacturing $62,000 worth of goods per annum, 1 woollen mill producing 475,000 yards of stuff, and 2 paper mills producing $10,500 worth of paper. In 1858 it contained 4 churches.

DRAFT, a word used indiscriminately with the synonymous term DRAUGHT, from which, according to Dr. Webster, it is corrupted. Although no less than 17 definitions are given in his dictionary, no mention is made in this or in Worcester's of the common use of the word to express a current of air; as the draft of a chimney—to sit in a draft of air. In the former application it is also used to express quality, as a chimney of strong draft; so the word is used in the example given by Dr. Webster of a cart of easy draft, expressing "the quality of being drawn."

DRAGOMAN, an oriental word signifying interpreter. It is applied, in the Ottoman empire and the courts of the further East and of Barbary, to men who know several languages, and make it their business to act as interpreters between foreigners and the natives. What was formerly a necessity for commercial relations, has since become so for purposes of diplomacy. At Constantinople the office of prime dragoman, through whom the sultan receives the communications of Christian ambassadors, is one of the most important of the Sublime Porte, and is usually held by a Greek, belonging to one of the most illustrious families of his nation. Most foreign ambassadors and consuls in the ports of the Levant, and many travellers, keep private dragomans at their own expense.

DRAGON (*draco*, Linn.), an iguanian lizard, of the subfamily of acrodonts, or those having the teeth implanted in the bony substance of the jaws, to which they firmly adhere by the base of the roots. The head of these reptiles is triangular, flattened, and covered with small irregular scales, sometimes ridged; the small circular and tubular nostrils open at the end of the obtuse snout; the tongue is thick and spongy, with a round single extremity; the anterior teeth are 3 or 4, and resemble incisors; behind these the median ones are conical, like canines, and there are generally 2 pairs in each jaw; the posterior teeth, or molars, are tricuspid and compressed; under the neck is a long crest or dewlap, and on each side a triangular cutaneous fold placed horizontally, all 3 having in their thickness a process from the hyoid bone; there is generally a small cervical crest. While some species have no external ear, in others there is a small circular membranous tympanum. The neck is slightly compressed; the body has a central dorsal depression, and is covered above and below with small imbricated ridged scales. Dragons are at once distinguished from all other reptiles of this order by the horizontal expansion of the skin of the sides into a kind of wing, supported chiefly by the first 6 false ribs, which are extended horizontally outward instead of surrounding the abdomen. This flying membrane, of a semicircular form, is about as wide as the arm is long, free in front, but attached behind to the anterior part of the thigh; in a state of rest the animal keeps it folded like a fan along the body, and spreads it like a parachute to sustain it when leaping from branch to branch; it cannot be moved as an active organ of flight like the wing of a bird or the membrane of the bat, but serves only as a passive supporting instrument like the parachute membrane of the flying squirrel; both surfaces of this membrane are furnished with very small smooth scales. The fore and hind limbs, each with 5 toes, are of about the same length, the latter being flattened, with the posterior border fringed with serrated scales; there are no femoral pores; the tail is very long, slender, wide and flat at the base, round at the end, with rhomboidal imbricated scales, strongly ridged beneath. Among the species with a visible tympanum, and the nasal openings directed laterally, are: 1, the fringed dragon (*D. fimbriatus*, Kuhl), with the thighs fringed behind with triangular scales, and with longitudinal white lines on the wings; the general color above is an olive gray with shades of brown in transverse bands, and whitish below; this is the largest species described by Duméril and Bibron, the total length being about 11 inches, of which the body is only 3; it is peculiar to Java: 2,

the flying dragon (*D. Daudinii*, Dum.), from Java, of a grayish color above with black spots, and the wings marbled with the same; total length about 9 inches: 3, the Timor dragon (*D. Timorensis*, Peron.), with wings spotted with brown on a reddish ground, and a row of ridged scales larger than the rest on each side of the median line of the back; length about 8 inches; probably a variety of the last: 4, the banded dragon (*D. quinquefasciatus*, Gray), with 5 brown bands traversing the upper surface of wings and back; from the East Indies; about 10 inches long. The dragon of Dussumier (*D. Dussumieri*, Dum.) has the nostrils opening vertically, the wings spotted with brown near the body and widely marbled with the same on their upper free edge, and a black band across the lower surface of the neck; length about 8 inches; it is a native of the continent of India. The red-bearded dragon (*D. hæmatopogon*, Boie), from Java, has vertical nostrils, and a large black spot on each side of the red gular pouch; length about 9 inches. There are 2 species which have the tympanum concealed under the skin, constituting the genus *draconculus* of Wiegmann; these are the lined dragon (*D. lineatus*, Daudin) of Amboyna and Celebes, about 6½ inches long, with the back ash-colored, and the wings grayish brown with longitudinal white lines; the Philippine dragon (*D. spilopterus*, Wiegm.), from the neighborhood of Manila, about 8½ inches long, with red wings spotted with black or brown, and throat yellow with black dots. Dragons live almost entirely in trees, and feed upon insects, which they catch with dexterity.

DRAGON, an animal often alluded to in the Bible, supposed by some to be the crocodile, and by others to refer, in some passages, to a species of giant serpent, or to a wild beast like the jackal or wolf. According to Robinson's Calmet, it is not improbable that St. John had in mind the enormous boa of Africa and the East when he described the symbolic great red dragon.—In mythology, the dragon is a fantastic animal, variously represented as of immense size, with wings, thorny crests, powerful claws, and a snaky tail and motion. He figured in the ancient conceptions of the Orient and of the classical nations, was a familiar subject in the middle ages, is still an emblem of universal use among the Chinese, and seems to have existed almost everywhere except in nature.

DRAGON-FLY (*libellula*, Linn.), an insect of the family *subulicornes* of Latreille, and the order *neuroptera*. The insects of this genus, in this country commonly called "devil's needles," in the perfect form are light and graceful fliers, of the most brilliant and beautiful colors, with 4 large, shining, delicate wings of nearly equal size; the mouth is arranged for crushing insect prey, provided with strong horny mandibles and spiny maxillæ; the eyes are lateral, large, and brilliant, with 3 stemmata upon the top of the head; the antennæ consist of from 3 to 6 joints; the legs are short, 6 in number, directed forward, arising from a firm thorax formed of 3 united segments; the abdomen is very long, a flattened cylinder, soft, without sting or piercer, and in the males terminated by 2 lamellar appendages. In some genera the male sexual organs are placed in the 2d abdominal ring, and those of the female in the last ring, which requires an unusual position in the act of reproduction; the female deposits her eggs on aquatic plants beneath the surface of the water. From their lightness and beauty the French call them *demoiselles*. Kirby speaks of their "dress" as "silky, brilliant, and variegated, and trimmed with the finest lace;" Mouffet says they "set forth nature's elegancy beyond the expression of art;" yet with all their gay coloring they are among the most voracious and cruel of insects, darting with hawk-like swiftness and ferocity upon gnats, mosquitoes, butterflies, and almost any soft-bodied winged insect, eating even their own species. They are not only in no way injurious to man, attacking neither his person, cattle, nor crops, but are directly beneficial in destroying many noxious insects. They hover over pools in search of prey, or dart from a post or fence upon insects coming near; having caught one, they alight to devour it, first pulling off the wings; in their habits they resemble the fly-catchers among birds. They are equally carnivorous in the larva state, which they pass in the water. The larvæ are without wings; they have 6 feet, and a very complicated arrangement of the parts forming the under lip, which covers the face like a mask, concealing the mouth, and serving by the unfolding of its plates for seizing and conveying food to the mouth; they crawl stealthily along the bottom, like a cat, and when within reach spring their jointed mask upon insects and even small fishes with great precision. By a valvular apparatus at the end of the tail, these larvæ draw in and expel water, using the jet against the surrounding stationary fluid as a means of locomotion; the currents thus produced also bring insects within reach of the jaws, and doubtless serve some of the purposes of respiration, though respiratory tracheæ also exist on the sides of the body. They remain several months in the water, and change their skins several times. The nymphs have rudimentary wings, and when they are ready to assume their final change, the brilliant eyes of the future fly may be seen through the envelope, which becomes more transparent; they crawl out of the water upon some bank or aquatic plant, where the pupa skin becomes dry and crisp and bursts open on the back; the head and legs of the perfect insect are slowly thrust and drawn out, the wings gradually expand themselves and become smooth, and the body and limbs assume their just proportions. During the drying of the wings the insect bends the body into a crescentic form, that their delicate tissue may not be disturbed by contact with any foreign substance. The anterior nervures of the wings must be very strong, though light, to enable the rapid vibrations of these organs to be performed; their sec-

tion, as in the butterfly, would probably present the form found by engineers to be that of the beam of greatest strength and lightness, viz.: the greatest amount of material thrown into the oval flanges, connected by the thinnest possible median support. According to Drury, these insects are 2 years in reaching the perfect form from the egg; after flying about a few weeks, and having performed the act of reproduction, the wings become ragged, the strength fails, and they soon die. They are sometimes seen in immense swarms; M. Poey says that at certain seasons of the year the north winds sweep hosts of them into the neighborhood of Havana; in Belgium in 1854 a swarm was seen extending ¾ of a mile, and requiring nearly an hour to pass a given spot, the lowest individuals flying at a height of about 6 feet. The restricted genus *libellula*, of which nearly 20 species inhabit New England, has a flattened, moderately long body, an almost globular head, the eyes contiguous or approximate, and the wings horizontal when at rest. The larvæ are short and thick, of a rough appearance, and a dirty color; they have 5 appendages to the tail. The genus *æshna* (Fab.) includes the large species, with long slender bodies, which keep the wings expanded when at rest; the larvæ are larger, long and slender, with the abdomen flat below and rounded above; this includes the *L. grandis* (Linn.), the largest and most predaceous of the British genera; there are about a dozen species in Massachusetts. In the genus *agrion* (Fab.) the wings are perpendicular during repose, the head transversal, and the eyes far apart; this includes the species with the slender and filiform abdomen, sometimes of extraordinary length; the larvæ are small, with round slender bodies terminating in 3 feathery appendages; there are about 10 northern species well known, many of them delicate and beautiful; among the foreign species are some of the most brilliant of insects. Many of the finest American species of this family are described and figured by Drury.

DRAGON'S BLOOD. See Balsams.

DRAGOONS (Fr. *dragons*, from Lat. *draconarius*, a standard bearer), a species of cavalry first introduced by Marshal de Brissac in France in the 16th century, when they were armed with muskets and trained to fight according to circumstances either as cavalry or infantry. They manœuvred either in or out of the line, extended themselves as skirmishers on the wings, fired upon the enemy, and then deployed behind a column of infantry to reload their pieces, promptly returning again upon their adversaries. They were subsequently of especial service in passing rivers and defiles, and as an escort for the baggage and convoys of artillery. In the 18th century they lost their hybrid character, were generally used as cavalry, and now form in most of the European armies a grade between cuirassiers and hussars, mounted on horses too heavy for the latter and too light for the former. Nicholas of Russia created a dragoon corps of 8 regiments designed to act either as cavalry or infantry, but they were reduced to simple cavalry by his successor. The first corps of dragoons in England, called the royal regiment of dragoons of North Britain, was raised in 1681, and is now the Scots greys. There are two regiments of dragoons in the U. S. army. (See also Cavalry.)

DRAGUIGNAN, a town of France, capital of the department of Var, 41 m. N. E. from Toulon; pop. in 1856, 9,900. It rises in the midst of a fertile valley, surrounded by high hills covered with rich vineyards. It is well built, with several elegant edifices, and numerous fountains. It contains a library of 15,000 volumes, among which are a few very valuable works, a cabinet of medals and of natural history, law courts, a parish church, and a fine clock tower. The inhabitants are employed chiefly in the silk mills and soap works of the environs, and in preparing and selling olive oil. Draguignan is an ancient town; was last fortified in 1615; and its possession was a matter of contention in many of the wars of France.

DRAINAGE, the art of freeing land from superfluous water by causing it to flow off in channels or through porous substances. The system of drainage adopted for cities and towns is commonly described as Sewerage, and will be noticed under this head, as that of mines in the article devoted to that subject. (See also Pump.) The art is of especial interest in its application to the reclaiming of wet lands, and the improvement of those through which the water that falls upon them in rain, or is brought by subterranean channels, does not find a ready exit. The importance of this branch of the art appears to have been appreciated by the ancient Romans, who are known to have constructed open drains for conveying away the superficial water from their lands, and to have laid underground water pipes of earthenware, which some suppose were for the same purpose, but which are with more probability referred by others to the purposes of aqueducts for supplying water to their houses. In England public attention was directed to the injurious effects of water retained in cultivated lands by the treatise of Capt. Walter Blyth in 1652. In this work the tendency of wet lands to produce the flag and rush instead of useful crops was forcibly portrayed, and the remedy of deep drainage as strongly urged. The author condemned the shallow open drains in common use, and recommended straight trenches reaching below the spring of "cold, spewing, moyst water," which he regarded as the source of the "corruption that feeds and nourisheth the rush or flagg," even to the depth of 3 or 4 feet, and the filling in of the trenches with stones, or with faggots covered over with turf. It was long, however, after his time before the excellence of this system was generally recognized, and little attention appears to have been directed to the subject until the latter part of the next century. About the year 1764 a shrewd farmer of Warwickshire, Mr. Elkington, undertook to investigate the peculiar qualities

of one of his fields in which the sheep were badly affected by the rot. He discovered that when an impervious stratum beneath the soil was perforated with an iron bar, the water confined below welled up and flowed away; and he hence inferred that the water in wet lands came chiefly from subterranean sources, and might be removed by tapping the stratum that confined it, and thus letting off the superfluous quantity. On this theory he established an original system of drainage, and was himself remarkably successful in seeking out the sources of the water, the supplies of which, after reaching by an auger, he drew off in a single deep channel dug for the purpose. This system came into extensive practice in England and Scotland, and its imperfections were not fully appreciated till after the introduction of the system of Mr. James Smith of Deanston, first brought forward in 1823. This, which its inventor called frequent or thorough drainage, and others named the Deanston system, was contrived with reference to the removal of the water collected by rains upon the surface, as well as that lying beneath the soil, and was in fact the practice recommended nearly 200 years before by Capt. Blyth. A series of parallel drains were sunk in the direction of most rapid descent, and being partially filled with stones small enough to pass through a 3-inch ring, were covered over with soil. At the bottom a main drain was constructed, of sufficient capacity to convey away all the water from the smaller drains, and this he directed should be made in stone work or with tiles. The new practice met with great opposition from the advocates of the method of Elkington, but finally came to be regarded as the only complete system applicable in all cases. In some instances the other plan may no doubt be economically adopted. The drains came at last to be made chiefly of tiles, for the manufacture of which the first machine was invented by the marquis of Tweeddale. The practice has been successfully introduced into the United States; and in Albany and New York draining tiles are already a considerable branch of manufacture. They are also made in New Jersey, Pennsylvania, and Ohio. Their forms and the manner in which they are used will be described after a few remarks upon the necessity and effects of drainage.—Wet lands are well known to be unfavorable to the production of large crops; it is also true that grains, potatoes, grass, &c., are of sounder and better quality when grown upon lands not subject to excess of moisture. The soils that retain it are correctly described as cold, while the more porous soils of a sandy nature are called warm. The former are chilled by the evaporation continually going on, while the latter are warmed below by the rain water which percolates through from the surface, and are heated by the direct action of the sun's rays. By the experiments of Mr. Parkes in a bog in Lancashire, it appears that by giving free passage to the water through a cold soil by thorough drainage, its temperature at the depth of 7 inches may be raised 10° above that of undrained adjoining land of the same quality. Thus drainage produces the effect of a warmer climate, and may add in fact many days to the length of the season; and this not merely by reason of the warmth extended for a longer period, but in the spring the soil is sooner prepared for cultivation, and may be in condition for ploughing and planting even two weeks before neighboring land of similar quality in other respects would admit of the passage of oxen and horses for working. An instance of such a gain in time was reported in 1856 by the secretary of the board of agriculture of the state of Maine. In the late spring of the northern states, where the snow often lies in April, and the ground is saturated with moisture in May, the advantage thus secured is of great importance. While frequent accession of water is a great benefit to lands through which it finds a ready passage, its retention impairs in various ways the fertility of the soil. It prevents the pulverization of the earth by the plough and harrow, and the circulation of air to the roots of the plants. It nourishes a growth of noxious plants, and in woodlands its injurious effect is seen in the production of many lichens, fungi, and other parasites upon the trees. Even the cattle and sheep pastured upon wet lands are subject to diseases from which those in dry fields are comparatively free, and are moreover pestered by swarms of flies and mosquitoes, which disappear as the same lands are drained. Man himself is often the greatest sufferer from undrained lands, which tend to engender fevers and agues; and these are known to prevail long after the forests have been removed, showing that the cause is not so much the decay of large bodies of vegetable matter, as the cold dampness produced by the saturation of the earth with moisture. By the recent researches of Dr. H. I. Bowditch of Boston, it appears that consumption also is more prevalent in those localities in Massachusetts which are badly drained, 50 out of 55 districts in the state of decidedly consumptive character being found wet by contiguity to ponds or marshes, or by reason of low and springy lands. In the vicinity of the wet and unhealthy localities are often found others which appear to be as free from any tendency to induce or aggravate the disease as the distant regions to which patients are sent for recovery. It is a singular fact, fully established by experience, that undrained lands are more liable to suffer from drought than those thoroughly drained. The former in a dry time become baked and compact, and do not readily absorb moisture from the atmosphere; but a well pulverized and open soil receives into its pores and absorbs like a sponge the dew and aqueous vapor in the air. The moisture finds its way to the lower portions of the soil, and is there taken up by the rootlets, which penetrate deep into the loosened materials. Deep or subsoil ploughing is thus seen to be most advantageously employed in connection with underdraining. The same cause which prevents the

penetration of the water also keeps near the surface the fertilizing substances applied as manure; and these exposed to the heat of the sun are in great part dissipated, their richest ammoniacal portions going off in exhalations to be precipitated by the rains upon other lands. Undrained soils in cold climates suffer from another cause. They are liable to freeze when saturated with moisture; and as they thaw, or, in popular language, as the frost comes out of the ground, they are so heaved and broken up, that the roots of the grasses and winter grains are thrown out, and the plants are destroyed; this is what is called winter-killed. By draining and subsoiling, a way is opened for the moisture to sink beyond the reach of frost, and the soil is left too dry to be disturbed by the thaws of spring.—From these remarks may be inferred the inutility of mere surface draining. Open trenches may convey away the surface water, but do not reach the cold stagnating repositories beneath the soil, which check that free circulation of fluids which is as essential to the health of vegetable bodies as that of the air to animals. Such ditches should be used only as brooks in the lowest grounds to convey away the water discharged into them by the underground drains coming down the slopes. Deep ditches partially filled with small stones or with brush, or laid at bottom with flat stones, are found by long experience to be not so well adapted to accomplish the object sought for as drains laid with tiles. These are short pipes moulded and baked of brick clay. Some are of cylindrical shape; and in others, called the horse-shoe tile, the section is an incomplete circle, and when laid the tiles are placed upon the 2 edges, either directly upon the ground, or separated from it by the intervention of flat pieces of the same material, placed so as to break joints with the tiles. In another form which is very generally used, called the sole tile, the flat bottom piece, instead of being separate, is a part of the tile itself, and is the foot upon which it stands. This and the pipe tile are considered far superior to the horse-shoe. Tiles are made of various sizes from 2 to 8 inches diameter, moulded by machines in lengths of about a foot, and baked as thoroughly as common hard-burned bricks. They are carefully set in the ground end to end; but the cylindrical pipes are often furnished with a collar which slips over and holds 2 adjoining ends. The bottom of the trench is dug with excavating tools, made for the purpose, just wide enough to admit the tiles. The water filtering through the soil passes into the pipes by the numerous joints, entering chiefly at the bottom, and the multiplication of these joints is the chief object of the short lengths. Tiles should always be imbedded in compact soil, and at a depth somewhat dependent upon the contour of the ground as well as other circumstances. A sufficient slope must be secured for the water to flow readily through the drains. There should be no interruptions to the descent, causing depressions in which sediment might accumulate to obstruct the drainage. The least fall admitted by most authorities in the usual sized drains is not less than 1 in 600 or 700; but so gentle a slope is rarely advisable; indeed, not less than 1 in 200. The depth generally agreed upon as the best is at least 4 feet. The tiles are at this depth rarely reached by a hard frost, and are not disturbed by the pressure of the subsoil plough, which penetrates a few inches over 2 feet below the surface. This depth is also lower than the roots of most of the crops are likely to extend; but the tiles cannot be placed beyond the possibility of injury from the roots of willows, poplars, and other trees which strike down in an open soil to uncertain depths. Their distance apart should depend upon the nature of the soil. In compact clays they have been set within 15 feet of each other; but this is unnecessarily close. If the subsoil be clayey, it is not well to exceed 30 feet; for if the drains once laid are found to be ineffectual, as they have in many instances proved, the only expedient is to make an additional one between each 2 of the original set. If the subsoil is very porous, the tiles may be placed 40 feet apart; but if trials at a greater distance than this are ever found effectual, it is believed their success should be referred to the principle of Elkington, the drains tapping a porous stratum containing water which was kept from flowing by an impervious overlying stratum. The effect of drains is not always perceived immediately after heavy rains. Some time is required for a dry soil to become saturated, and the moisture is then gradually given off below. The plants thus have sufficient opportunity to obtain the benefit of the water which passes through, and no danger is incurred of overdrainage, especially as the lands are left in better condition, as already stated, for absorbing atmospheric vapor. In stiff clayey soils the operation, though it would at first appear impracticable, is greatly facilitated by the property of the clays to shrink and open in cracks in passing from a wet to a dry state. This process commences near the drains, and the cracks extend back, serving as they open as minor channels for leading the water down to the tile beds. They have been traced stretching across through the clay with innumerable ramifications nearly from one drain to the next; and though they close again when very wet, they still let water pass along their lines.—The most extensive agricultural drainage operations in the United States are on the farm of Mr. John Johnston, near Geneva, N. Y. By steadily pursuing the practice for about 20 years, he has accomplished the laying of 210,000 tiles, or over 47 m. An instance of their beneficial effect was observed a few years since, when by the destructive action of the midge the crop of wheat upon 6 adjoining farms was reduced to 7 bushels per acre, while he obtained 29 bushels. The system of drainage adopted in the central park of New York city, under the direction of George E. Waring, Esq., is very complete, and

exhibits some peculiar features. The soil is chiefly a clay loam, and in this the drains are dug mostly from 4 to 5 feet deep, at distances apart of 40 feet, and directed down the line of steepest descent. The depths of the excavations are regulated by grade stakes set at the intersections of the drains, and at various points on their lines, the levels of which are taken, as in railroad excavations, and from these points the whole plan is prepared. In this no fall is admitted less than 1 in 200, and no diminishing slope toward the outlet if this can be avoided. The small drains discharge into the tops of the main drains. Where a diminishing slope toward the discharge cannot be avoided, a "silt basin" or catch-pool, formed of brick or of a large tile set on end, is placed on the line of the drain to retain the sediment. A silt basin of about 3 cubic feet capacity receives the drain of every 20 acres. It is built up to the surface, and furnished with an iron cover, secured by lock. This affords an opportunity of examining at any time the condition of the drainage, and of removing the sediment which is deposited. By reference to the plans of the work kept in the office, changes and additions may at any time be introduced in accordance with the general system.—The expense of underground drainage seriously checks the extension of the practice. The 2-inch sole tile, or 2½-inch horse-shoe tile, costs $12 per 1,000 feet length, and the prices rapidly increase up to $80 for 1,000 feet of 6-inch sole tile, and $60 for the same length of 6½-inch horse-shoe tile. The least expense per acre in nearly all arable soils for proper drains properly constructed may be estimated at from $35 to $50.—In Europe the largest draining operations have been those designed for reclaiming immense tracts of submerged or boggy lands, some of which were altogether below the level of natural drainage. As early as 1436 attention was directed to the possibility of reclaiming the fens bordering the river Ouse and its tributary brooks. These covered an area of some 400,000 acres of land, which in ancient times appears to have been in a condition for cultivation. The tract is partly in Cambridgeshire and Huntingdonshire, extending into the adjoining counties, by the high ridges of which it is bounded. It receives the waters of 9 counties, and presents but very limited natural channels for conveying these into the sea on the N. E. The attempts to embank and deepen these in the 15th century were unsuccessful, and the undertaking was abandoned till 1634, when it was renewed by the earl of Bedford. In 3 years he expended £100,000 in embankments for keeping out the waters of the rivers, and removing those within by pumping machinery and discharging them over the dikes. This attempt also failed; but in 1649 his son recommenced operations, and finally succeeded after the expenditure of £300,000 more. From that time the lands reclaimed—now known as the Bedford Level—have been kept free from water by means of efficient machinery, worked by windmills. The great difficulty appears to have been in securing main channels of sufficient capacity to discharge the waters in time of freshets; and through want of these the banks were often overflowed, and the former works washed away. Among the numerous drainage channels cut through these lands are 2 nearly parallel, of more than 20 m. in length, and both navigable, serving to cut off a long circuitous route of the river Ouse. By other direct channels made during the present century above the outlet of the same river, and also of the neighboring river Nene, many thousand acres more of land have been reclaimed. The steam engine has been advantageously substituted in many instances for the windmills; and it has been found practicable to estimate closely the power and expense required to keep an area of given extent thoroughly drained, the drainage from neighboring high lands being cut off by catch drains, and the height to which the water must be raised being known. The annual fall of rain averaging 26 inches, there would be, with a very moderate allowance for evaporation, 2 inches per month of water to be raised, or 1⅓ cubic feet of water as a maximum on every square yard of surface. The amount upon an acre, or 7,260 cubic feet, may be raised to the height of 10 feet and discharged in about 2 hours and 10 minutes by the power of one horse. A steam engine of 10 horse power could then each month raise to the same height and discharge the water from 1,000 acres in 232 hours. Similar calculations may be made for the drainage of submerged lands in the United States, proper allowance being made for the difference in the annual fall of rain in the district from that which occurs in England.—The drainage of the Haarlem lake in Holland, undertaken in 1839, was a gigantic operation of this class. From an area of 70 sq. m. of average depth of water of 12¾ feet, situated below the level of any sluices that could be constructed, it was required to raise the water an average height of 16 feet, and to an estimated possible amount of 35,000,000 tons in a single month. An enormous steam engine was constructed in London for working 11 pumps of 63 inches diameter each, and 10 feet stroke, the maximum capacity of all which was to raise 112 tons of water 10 feet at each stroke. These were set around the circular tower which contained the engine, and from the upper portion of which the balance beams radiated—one for each pump. They raised in actual work 66 tons per stroke, discharging the water in a large canal 38 miles in length, and from 115 to 130 feet in width, which had previously been constructed around the area. Two other similar engines were applied to the same work, and the pumping was continued from May, 1848, to July 1, 1852. Then the area was thoroughly drained, and the lands were ready to be divided out for sale. The entire expenses from the commencement of operations in 1839 to the close of 1855 were estimated at £748,445, which would be more than

paid by the proceeds of the sale of the lands, the greater part of which had then been disposed of. The swamp lands and salt water marshes of the United States present vast and almost untouched fields for this system of operations. The accumulations of vegetable matters they contain give fertility to the soil, when the stagnating waters are removed; and the success that has attended small operations undertaken to bring them into cultivation, gives encouragement to expect great results from operations undertaken upon a larger scale.—The subject of drainage may be further studied in the number of Weale's "Rudimentary Series," by G. D. Dempsy, "On the Drainage of Districts and Lands." It is also treated in an article in the U. S. patent office "Agricultural Report" for 1856; and by H. Colman in his reports of European agriculture. The very complete treatise of James Donald has been recently republished in New York; and William McCammon, civil engineer of the "Albany tile works," has presented in an advertising pamphlet a summary of the principles and advantages of drainage, with exact descriptions of the tools and methods employed and estimates of cost.

DRAKE, Daniel, an American physician, born in Plainfield, N. J., Oct. 20, 1785, died in Cincinnati, O., Nov. 5, 1852. His father, a farmer in indigent circumstances, emigrated from New Jersey to Mason co., Ky., in 1788, where Daniel's childhood and youth, up to his 16th year, were passed on a small farm, amid the labors and privations of a frontier life. In Dec. 1800, with only such education as he had received in the course of some 6 months' desultory attendance at different times upon country schools, taught by wandering and ignorant schoolmasters, he was placed under the care of Dr. William Goforth, of Cincinnati, as a student of medicine, and in 1804 he commenced the practice of that profession. In 1816 he was graduated at the university of Pennsylvania, and in 1817 he was invited to a professorship in the Transylvania medical school at Lexington, Ky., in which he lectured one session. In Dec. 1818, on his personal application, the legislature of Ohio granted a charter for the medical college of Ohio, at Cincinnati, and also established there the commercial hospital. In the autumn of 1820 the former institution was opened for students, and for 2 sessions Dr. Drake was connected with it. In 1823 he again accepted a chair in the Transylvania school; and thenceforth, till the close of his career, was with brief intermissions connected with medical schools, holding professorships in that institution, and in the Jefferson medical college, Philadelphia, in the Cincinnati medical college, in the university of Louisville, and finally, again, in the medical college of Ohio, with which he was connected at the time of his death. As a professor of the theory and practice of medicine he held an eminent position, and as a practitioner his reputation was coextensive with the Mississippi valley. His writings were voluminous, but principally of a character not calculated or intended for permanent use. His first book, the "Picture of Cincinnati" (1815), attained in its day a wide reputation, and drew from Thomas Jefferson a highly complimentary letter. His last work, upon which his fame as an author must principally rest, was "A Systematic Treatise, historical, etiological, and practical, on the Principal Diseases of the Interior Valley of North America, as they appear in the Caucasian, African, Indian, and Esquimaux Varieties of its Population," vol. i. of which was published in 1850, and vol. ii., posthumously edited, in 1854. A memoir of his life and services, by Edward D. Mansfield, LL.D., was published in Cincinnati in 1855.

DRAKE, Sir Francis, an English navigator, born near Tavistock, in Devonshire, according to some authorities in 1539, and to others in 1545 or 1546, died Dec. 27, 1595. His father, a poor yeoman, and a recent convert to the Protestant faith, obtained from Queen Elizabeth an appointment as naval chaplain. He had 12 sons, of whom Francis, the eldest, received a scanty education through the liberality of his kinsman John, afterward Admiral Sir John Hawkins, and as soon as he was old enough to serve as a cabin boy, was apprenticed to the master of a bark. By his industry and frank and decided character he so gained the affections of his master, that the latter at his death bequeathed his vessel to his young apprentice. Being thus at the age of 18 years a good sailor and the proprietor of a ship, he quickly completed his education by learning how to command, and made a commercial voyage to the bay of Biscay and afterward to the coast of Guinea. Inspired by the adventures and successes which the new world then offered, he sold his vessel and invested the proceeds with all his savings in the expedition of Capt. Hawkins to Mexico in 1567, receiving the command of the Judith. The fleet was attacked by the Spaniards, and only 2 of the 6 ships escaped. Drake, barely succeeding in saving his own vessel, returned to England, with a loss of his entire property, and fruitlessly petitioned the court of Spain to restore what its subjects had taken from him. Then with an oath he declared that he would obtain by force the rights which he could not get otherwise, and began to sail with the avowed object of pillaging the Spaniards. In 1570 he obtained a commission from Queen Elizabeth. In 1572 he armed 2 ships at Plymouth, with which, joined by a third at Port Pheasant, on the coast of South America, he made a descent upon New Granada, captured and plundered various Spanish settlements, and made at the expense of his enemies a fortune vastly larger than they had taken from him. He returned to England in 1573, and was welcomed as a hero. While at Darien he had seen from a mountain top the waves of the Pacific, and had there conceived the purpose of an expedition into those waters, yet unexplored by English vessels, which he now prepared to execute. His eloquence was sufficent to gain the patronage

of Elizabeth, to whom he exposed the feebleness of Spain in her colonies and promised treasures and conquests. He set sail from Plymouth, Dec. 13, 1577, with 5 vessels and 164 gentlemen and sailors, to follow the route which had been traced by Magellan. While in Port San Julian on the coast of Patagonia, he put to death Captain Doughtie, a good sailor and brave officer, and a gentleman of birth and education, who was charged with having conspired against the life of the admiral. Directing his course to the N., Drake pillaged the Spanish settlements of Peru and Chili, captured a royal galleon richly laden with plate, and took possession of California in the name of the queen of England, and then, burdened with gold, sated with vengeance, and fearing to meet the Spaniards in superior force if he returned upon his steps, he sought to find by the N. E. a passage back to the Atlantic. Being repelled by the severe cold, he changed his purpose, and determined to make the circuit of the globe. He traversed the Pacific ocean, the archipelago of the Spice islands, the Indian ocean, doubled the cape of Good Hope, and arrived at Plymouth, Sept 26, 1579. Elizabeth received him with favor, and 4 months afterward knighted him, and partook of a banquet on board of his ship. The rupture which followed between Elizabeth and Philip II. gave Drake a new opportunity to gratify his animosity against Spain, and within one year he captured and plundered Carthagena and several other towns, burned the forts of San Antonio and Saint Augustine, and visited and brought away with him the remains of the colony which Raleigh had planted in Virginia. In 1587 he was placed in command of a fleet of about 30 sail designed to attack the Spanish ports. He destroyed 100 ships in the harbor of Cadiz, an exploit which he spoke of as singeing the king of Spain's beard, and soon after captured an immense carrack, from papers in which the English first learned the value of the East India traffic, and the mode of carrying it on. In 1588, as vice-admiral, he commanded one squadron of the fleet by which, with the assistance of the elements, the "invincible armada" was annihilated. In 1589 he ravaged the coasts of the Spanish peninsula, leaving fearful traces of his passage, and in 1592 and 1593 was a member of parliament for Plymouth. In 1594, a report having reached England that Spain was preparing against that country a fleet more numerous and powerful than the armada, he again entered the service against his old enemy. Convinced that the West Indies was the point where Spain could be best attacked, he sailed for America in 1595 with 26 vessels, in company with Admiral Hawkins. A divided command produced its usual bad results, and their first attempts were unharmonious and fruitless. At Porto Rico Admiral Hawkins died, either of a wound or of chagrin, and Drake then in the region where his first anger against Spain had been kindled gained new triumphs. He burned Santa Marta, Rancheria, Nombre de Dios, and Rio Hacha; but a fatal malady broke out among his sailors, and as he heard of the defeat of a division of his forces which he had sent to operate by land, he himself fell sick, and died from the combined effects of fever and of mental agitation on account of the reverses of the expedition. His body received a sailor's funeral in sight of Puerto Bello, and was buried in the sea. Admiral Drake was one of the founders of the naval greatness of England; and though in his spirit and conduct there was something of the buccaneer, he was yet one of the most daring and efficient of naval commanders.

DRAKE, Joseph Rodman, an American poet, born in New York, Aug. 7, 1795, died Sept. 21, 1820. He lost his father in early life, and with 3 sisters struggled against adversity. He studied medicine, and his marriage in 1816, shortly after taking his degree, placed him in affluence. He travelled in Europe, and after his return in 1819 contributed under the signature of "Croaker" many pleasant and effective verses to the columns of the "New York Evening Post." His friend Fitz-Greene Halleck joined him in this series, signing his own pieces at first "Croaker jr.," but soon they both adopted the signature of "Croaker and co." The novelist Cooper was also one of the intimate associates of Drake, and a conversation between them as to the poetical uses of American rivers, in the absence of historical associations such as belong to the streams of the old world, was the occasion of Drake's longest and most imaginative poem, the "Culprit Fay." It was his aim to conjure up in this fanciful production all the associations of natural life and beauty which gather around a sylvan scene, and to show how the earth, the air, the sea, the field, the wave, the moonlight, are in themselves vital with poetical images and meaning. Though Drake had written verses from his boyhood, yet the poems which gave him his wide reputation as a writer of genius and taste were all the productions of a single season. His health failing, he passed the winter of 1819 in New Orleans, hoping to be benefited by the milder climate. But the progress of the consumption which had smitten him could not be arrested, and he lived but a short time after his return to New York in the spring. His death called forth a beautiful poetical tribute from his friend Halleck.

DRAKE, Nathan, an English physician and miscellaneous writer, born in York in 1766, died in Hadleigh, June 7, 1836. He was educated at the university of Edinburgh, and practised his profession in Hadleigh from 1792 till his death, during which time he was a frequent contributor to literary and medical periodicals. His works are numerous; they include "Shakespeare and his Times" (2 vols. 4to., London, 1817), and various criticisms and illustrations of the writings of the age of Queen Anne.

DRAKE, Samuel Gardner, an American author, born at Pittsfield, N. H., Oct. 11, 1798. He was educated at the common schools of the neighborhood, and between the ages of 20 and

27 was a district school teacher. Subsequently he removed to Boston, and in 1828 established an antiquarian book store, one of the first of its class in the United States. In 1825 his literary and antiquarian labors commenced with the republication with notes of Church's "Entertaining History of King Philip's War," of which several editions have since appeared. In 1833 he reprinted 5 old tracts, which, with the preceding work, comprise, in his opinion, all that can be recovered in relation to King Philip's war. In 1832 appeared his "Indian Biography," and in 1833 the "Book of the Indians, or History and Biography of the Indians of North America," a work of high authority for facts, and of which the 11th edition, much enlarged, appeared in 1851. His remaining publications on Indian history are "Old Indian Chronicles" (Boston, 1836), "Indian Captivities" (Boston 1839), and "Tragedies of the Wilderness" (Boston, 1841). Since 1847 he has edited the "New England Historical and Genealogical Register," which, under the direction of a historical and genealogical society in Boston of which he is president, has contained many valuable contributions to local and family history. His latest work is an elaborate history of Boston in 1 vol. royal 8vo.

DRAKENBERG, Christian Jacobsen, a Norwegian, remarkable for his long life, born in Blomsholm, Nov. 18, 1626, died in Aarhuus, Oct. 9, 1772, at the age of 145 years and more than 10 months. The son of a sea captain, he himself led a seafaring life till 1717, when he abandoned it on account of the dimness of his eyesight, though his strength and vigor were undiminished. In 1732 he was residing in Copenhagen, and his advanced age having been disputed by persons who judged from his looks that he was younger, he indignantly set off to procure his baptismal certificate, and having for that purpose performed a long journey through Sweden chiefly on foot, reappeared with his documentary proof at Copenhagen. He was married in 1737, and in 1759 still continued to exercise much in walking, and retained extraordinary strength. He died after a gentle sickness of 13 days. He was of medium stature, passionate, but rather temperate, with a good appearance and address.

DRAMA (Gr. δραμα, from δραω, to make), a story represented by action. The principle of imitation is inherent in human nature; painting, sculpture, and the drama must be coeval with society, and have been practised in some form by almost every nation. Among the South sea islanders a rude kind of drama was discovered. In China the drama dates its origin to remote ages. The war dance of the Indian and the African, intermingled with pantomimic descriptions of the preparations for battle, the stealthy advance upon the foe, the combat, and the death of the enemy, greeted with applause from the excited spectators, is essentially a dramatic exhibition, although wordless. But that form of the drama accepted and followed in Europe, divided chiefly into tragedy and comedy, was the creation of the Greeks about 700 B. C. The religious festivals of Bacchus were believed to have been introduced into Greece by Melampus. In the Bacchic ritual an ode in honor of the god was recited; and to produce the best ode, the one which should be selected by the priests to be inserted into their ceremony, became a favorite contest among the poets of the time. A goat was either the principal sacrifice at the altar, or the prize awarded to the successful competitor; thus from the two words τραγος and ωδη, the ode for the goat, came the Greek word τραγωδια, tragedy. In like manner, at the rustic festivals or harvest homes of the Greeks, semi-religious ceremonies, composed of odes and dances in honor of Bacchus, were enacted. These odes, being of a more genial and comic character, consistent with the occasion of an agricultural triumph, were called κωμωδια, comedy, from κωμη, village, and ωδη, song, the song of the village. Some writers are of opinion that the word comedy originally signified drama, and had not the distinctive sense in which we apply it, but included tragedies and theatrical representations of every kind.—The earliest known form of drama is the dithyrambus, a hymn in honor of Bacchus, sung by a chorus of voices, accompanied by music, expressive gesture, and dances. In 562 B. C., Susarion, a native of Megara, appeared at Athens, where he, as a single speaker, recited an ode. In 536 B. C., Thespis, a native of Icaria, recited an ode with responses made to him by a dithyrambic chorus; in this we faintly perceive the first germ of dialogue. Such were the rude elements found by Æschylus in 499 B. C., and out of them he alone and unaided created and perfected the drama as we now behold it. Nothing essential has since been added to its structure; he seems to have forestalled future ages of invention, and to have left nothing undone. He removed the chorus into the background, and used them only as an auxiliary. He brought a second actor upon the scene, and introduced dialogue; thus the drama became an action instead of a narrative. He invented scenery, costume, and machinery, of a grandeur unknown to our stage. Banishing the lewd and Bacchanalian character from the dithyrambic hymn, he supplied its place with pure tragedy, simple and grand in its form, noble and dignified in its object. From his works were gathered those rules called the unities, referred to by Aristotle; indeed, he may be truly said to have found the drama chaos, and left it a world. These changes were wrought within the space of 30 years, and so rapidly were they accomplished, that they were at the time regarded as the work of inspiration. The expansion he gave to the drama caused the Athenians to build the great theatre of Bacchus, the Lenaion, the former theatre having broken down under the pressure of the people gathered into it to witness a representation in which Æschylus and Pratinas were rivals. Thirty years later, Sophocles introduced a third actor, and thus diffused the dialogue and

fertilized the action. As a dramatic poet he surpassed Æschylus by a noble grace and a sweet majesty, which were wanting to the Titanic father of the drama. Fifteen years afterward Euripides enabled Greece to behold as contemporaries the three greatest purely tragic poets the world has produced. In reviewing their works we must remember that Æschylus was the creator of that fanciful world which Sophocles and Euripides so wonderfully cultivated. The dramas of Æschylus are dark, gloomy, and terrible; thunder and lightning are their atmosphere, and demigods their *dramatis personæ;* his human beings are gigantic in moral stature, and removed above our sympathies. Sophocles, more human but not less divine, drew human nature as it ought to be. Euripides, descending still further, depicted men and women as they were.—The origin of the drama is popularly but erroneously ascribed to Thespis. This improvisatore did no more than improve upon the dithyrambus; he first organized a regular chorus, and invented dances of peculiar energy and grace; but his performances were a kind of ballet farce. Of tragedy he had no idea.—The tragedy of the Greeks was a fable or a series of events begotten of each other in a natural sequence. It began with a simple position, so selected that the auditor required no explanation to understand the present condition of matters or persons; it was a simple beginning. The development of the characters was required to be simultaneous with the action, the one being involved in the other. The action should not stray from the one place beyond such a limit as the time employed in the performance might naturally permit; nor should a lapse of time take place during the piece beyond the limit of one day. These unities of action, place, and time, however, so strenuously insisted upon by the French dramatists, were not strictly observed by the Greeks, nor were they considered essential, for Æschylus himself did not always observe them. Aristotle refers indistinctly to the unity of action; he says in reference to the unity of time: "Tragedy endeavors as much as possible to restrict itself to a single revolution of the sun." Of the unity of place he says nothing. The Greek tragedy was composed in trilogies, or 3 distinct plays, continuations of each other; such, for example, was the trilogy of Æschylus, formed of the *Agamemnon*, the *Choëphoroi*, and the "Furies." In the 1st, Agamemnon, returning from the siege of Troy, is murdered by his wife Clytemnestra; in the 2d, Orestes, Agamemnon's son, avenges his father by the slaughter of his mother; in the 3d, Orestes is pursued by the Furies for this unnatural deed; the gods cannot agree upon his case until Minerva decides in his favor, and releases him from the torture of the avenging divinities. These 3 subjects conjoined formed a complete action, divided into a thesis, an antithesis, and a synthesis.—The early history of comedy is more obscure than that of tragedy. The earliest comic poet of whom we have remains is Aristophanes, who flourished a century after Æschylus. He was the last of what was called the old school. Comedy was divided into 3 forms, the old, the middle, and the new. In the first or old comedy, the characters were real living personages, who, under their real names, were freely satirized. This license was soon so abused that a law was passed forbidding the names of real personages to be used in comedy. This impediment produced the second or middle comedy, where the prohibition was evaded by giving fictitious names to real characters, and distinguishing the individual intended to be satirized by a mask or by some unmistakable inference. The middle comedy lasted about 50 years, when it was superseded by the 3d or new comedy; in this form the characters and the subject were fictitious, and as the old satirized and ridiculed statesmen, orators, and generals under their real names, so the new was aimed at abstract vice, and not at the individual offender. As tragedy descended from the contemplation of divine matters to depict and sympathize with human woes, it gradually lost its grandeur and depreciated. So, also, as comedy divested itself of its direct influence upon men and things, and from a statesman became a philosopher, it lost its pith and power.—The list of dithyrambic poets preceding Æschylus from 700 to 525 B. C. includes Archilochus, Simonides, Lasus, Arion, Stesichorus, Solon, Susarion, Hipponax, Theognis, Thespis (birth of Æschylus). Afterward came Chœrilus, Phrynichus, Epicharmus, *Æschylus* (invents the drama, and first exhibits 499 B. C.), Chionides, *Sophocles* (first victory 468 B. C.), *Euripides* (first exhibits 455 B. C.), Cratinus, Aristarchus, Ion, Crates, Achæus, Melanippides, Pherecrates, Phrynichus the comic poet, Lysippus, Eupolis, *Aristophanes* (427 B. C.), Agathon, Xenocles, Ameipsias, Sannyrion, Astydamas, Antiphanes, Theopompus, Eubulus, Alexis, Heraclides, *Menander* (first exhibits 321 B. C.), after whom the Greek drama died obscurely.—The Romans derived their drama from the Greeks. Terence, Plautus, and Seneca are the only Latin dramatists worthy of mention, and these are but translators and imitators of the Greek. The only element introduced by the Romans into the drama was farce, an invention of the Tuscans; buffoonery became more popular than wit. In truth the Roman people took little pleasure in pure intellectual amusement, and what the poet was to the Greek the gladiator was to the Roman. The coarser Roman preferred to watch the agonies of the body suffered in the circus, rather than sympathize with the woes of the soul simulated in the theatre.—Thus ended the first or classic age of the drama. The second, or romantic age, gave its first indication of existence in the 12th century, when dramatic performances called *entremets* were introduced, as the word implies, between the services at royal banquets and carousals. These entremets soon became pageants, masks, and mummeries, and lasted as distinct dramatic entertainments up to the period of Shakespeare. Simultaneously

a dramatic composition called a Mystery, usually founded on passages of Scripture, was introduced and became a popular exhibition on saints' days. Subjects from the Bible, rudely treated in the form of a dialogue between the holy personages, were represented on a stage erected in the church or church yard, the priests and acolytes being the actors. These performances were carried to an abuse, and they became so blasphemous a scandal that they were suppressed. The next form of drama was the Morality, bearing a relation to the mystery similar to that between the new and old comedy of the Greeks. The morality was aimed at abstract vice, its action was a fable, its characters typical.—In the 15th and 16th centuries Histories began to be written—long, rambling pieces of action without form or object, but introducing rudely the design of that romantic drama destined to so wondrous a perfection under the minds of Shakespeare and his colleagues. As the classic drama was derived from the dithyramb, a pure poetic germ, subsequently developed into action, the romantic drama was derived from the pageant, mask, or mummery, a pantomimic germ, subsequently developed into poetry. In the first the action is subservient to the passion; in the second the passion is subservient to the action. Thus we find Shakespeare borrows his plots from Boccaccio, and makes his passions fit under these forms, where his characters rather encumber than assist the intrigue. In the Elizabethan age the romantic drama sprang at once into existence; and as in the single life of Æschylus the classical or Greek drama passed from infancy to maturity, so Shakespeare and his colleagues raised the romantic or Gothic drama from rudeness to the highest perfection it has ever achieved. In the romantic drama the unities of time, place, and action are not observed. The poet is allowed unbridled license; prose and poetry may be mingled without rule or reason, beyond the aptitude of each to the moment and the character. In the Greek mind the sense of form was very acute; we see it in their architecture, sculpture, and poetry; we have it in their social and political institutions. The Greek taste demanded grace of outline, proportion of parts to the whole, and was so extremely sensitive to this element in art, that we find it in all things Greek which remain to us. The Gothic mind is eminently defective in this sense. The only ideas of form we have are derived from study of the ancient models, and are not inherent in us. Reckless of form, therefore, Shakespeare depicted characters and developed passions, flung them into groups, hurried them through the action, over the possible and the impossible, and landed them on a catastrophe not prepared by design, but which suited his convenience. His works present a glorious intellectual anarchy in which he has had no follower, for the reason that no mind of less power than his own could contend with the confusion he so marvellously controls. The romantic dramatists greatly excelled their classic rivals in the rich coloring of their characters; they drew men more like imperfect human beings and less like inspired statuary; and if less noble in contour, they were more truly flesh and blood. The Shakespearean characters are constructed piecemeal out of the small imperfections and humors that make up human nature; the Greek heroes are made of one piece, one passion. The English dramatists of this age gave originality at least to the form of the romantic drama, and, whatever its faults, it was new. The French and Italian poets clung to the Greek models; Corneille and Racine were but faint and poor imitators of Euripides; Alfieri affected the same ancient simplicity. As students of the Greek, their individual merit is great; but having had no share in the progress of the drama, they have no prominent place in its history. The Italians and Spaniards at this period contrived a species of performance, part pantomime, part farce, part comedy of intrigue. It was derived from those Italian narrators of whom Boccaccio is the best type, and represented dramatically those short and pithy tales in which Margaret of Navarre was wont to take such delight. Lope de Vega was the first to inaugurate this comedy of intrigue; it was quickly imitated and greatly improved by the French, who by admitting more Italian elements gave it variety and scope. Hardy, Rotrou, and Corneille, Scarron and Quinault, prepared the public taste for Molière, who truly founded and made the second or middle age of comedy, as Shakespeare and his colleagues made the first or old. Comedy at this time mainly occupied the stage. In England the four great masters, Wycherly, Congreve, Vanbrugh, and Farquhar, brought forth the prose drama. If inferior to Molière, they were less tainted with that leaning toward Greek classicality which has always retarded the true progress of the drama in France. The most original of Molière's works is the *Bourgeois gentilhomme*, because in its form and treatment he has exhibited more freedom from scholastic trammel. In the beginning of the 18th century the sentimental drama, a mixture of comedy and tragedy, a weak solution, obtained great popularity, but cannot be considered a forward movement in the art. In Germany this drama obtained great popularity under Kotzebue, and at the same time a wild, mythic, philosophical dramatic form of poem was created by Goethe and Schiller. These poets have rather embellished dramatic literature than added to the development or progress of the drama as an art. Lessing, who preceded them, may be said to have founded the German drama, but he attempted no reform.—The next and last great step which the drama has made, and one that has become prominent in the present age, is the invention of opera, or a drama in which music takes the place of poetry, and the dramatic action is subservient to a new musical development. It is a mistake to presume that an opera is a musical drama. The musical form of an opera and its dramatic treatment are essentially different from

the form and treatment of a drama based on the same fable. There is also in the form of the music, apart from the libretto, a plan and proportion to which the drama must be subservient.—Among the various minor forms of the modern drama are melodrama, farce, vaudeville, and pantomime. Melodrama owes its invention to the laws which restricted the performance of tragedies and comedies to certain privileged theatres. Booths were erected in which were performed serious pantomimes, or dramas without words, accompanied throughout with expressive music. By degrees the actors ventured a few extempore phrases or jests. This license was gradually extended, until dialogue was regularly introduced, and the music was only used to accompany the movement of the actors. Melodrama is now understood to be a drama wherein the passion and development of character are subservient to the action and plot; whereas tragedy is a drama where the action and plot are subservient to the passion and development of character. Farce is a humorous piece of buffoonery, in which probability may be outraged both in the incidents and character, and stands in relation to comedy as melodrama does to tragedy. Vaudeville is an invention of the French stage. Schlegel states that "vaudeville is only a variation of comic opera;" but it is essentially a different thing, and was in no manner derived from it, nor has it ever been connected with it. It has its name from *vau de Vire*, which was originally a satirical song containing a keen, witty thought, and applicable to some popular person or event. It was a lyric epigram invented in that part of Normandy called Vire, and carried thence to Paris, where these musical satires became the vogue. Presently the writers of small comedies threw their keenest epigrams into verse, by which they gave them more point and drew to them more attention; these verses might be sung to any air that would happily suit them, and were called vaudevilles. The comic pieces through which they were scattered eventually received the name. When the work is but slightly speckled with these musical epigrams,' it is distinguished as a *comédie vaudeville*, or a *drame vaudeville*. Pantomime is a drama without language, composed of gesture accompanied with music. It is probably the most ancient form of drama, and has changed less in its essential form than any other. The most perfect and most elegant kind of pantomime is the ballet, where graceful dances are interspersed amid the pantomimic action.—No work of the mind possesses such charms for the author as the drama; the combination of poetry, music, oratory, sculpture, and painting, represents an army of muses which almost every literary aspirant desires to command; but few are found adequate to the task. The first difficulty consists in the selection of a subject fit for dramatic treatment. Many fables read well, that lose the appearance of life when deprived of the peculiar charms of narrative, and given in dialogue. In the dramatist's language, "they will not act." Having secured a fit theme, it should be examined to see if it be agreeable. Thus in tragic subjects horror should be distinguished from terror. Horror has in it something repulsive; it has the ingredients of disgust to distinguish it from terror, which possesses a charm most attractive, having the ingredient of pity mingled in its sentiment. Provided with an appropriate subject, the dramatist must proceed to select a good beginning. If in his first act he has to employ his characters in long explanations of that part of his story which precedes the rising of the curtain, then has he made a beginning in the middle, as it were, and his drama is taking place off the stage, instead of upon it; for the mind of the auditor is fixed upon a scene described, and the action of the play ceases to give place to narrative; if he can find no means of avoiding these explanations, then he must consider that his subject is not susceptible of a good dramatic form. Having begun well, the action must never pause, and it must be continuous, for in this continuity is the secret of interest; it betrays an object which, though kept out of sight, is palpably ahead. As the plot proceeds, it should embrace nothing but what is essential to its support; whatever may be the beauty of an episode, it is a distraction, and has always more charms for the author than the auditor. Shakespeare triumphed over this fault so often that he has done great damage to the English dramatist by his example. At a certain proportionate distance from the end of the work comes the climax or catastrophe, toward which achievement all the action conspires. This event generally occupies the latter half of the 4th act in a 5 act play. The 5th is used to bring the fable in all its parts to a simple and clear conclusion, leaving a sense of completeness in the mind, where nothing remains to be desired or told.—A further account of the dramatic literature of each nation will be found under the titles of the respective countries. See also ÆSCHYLUS, ALFIERI, CALDERON DE LA BARCA, CORNEILLE, GOETHE, GOLDONI, LESSING, LOPE DE VEGA, MOLIÈRE, RACINE, SCHILLER, and SHAKESPEARE.

DRAMMEN, a commercial town of Norway, situated on the southern coast, in the province of Aggershuus, 20 m. S. W. from Christiania; pop. in 1855, 9,916. It lies on both sides of the river Drammen, and is composed of 3 small villages, separated from each other by natural limits. The commerce of which Drammen is the centre gives it the third rank among the cities of Norway, but in respect to its timber trade it stands first. It manufactures tobacco, earthenware, sail cloth, rope, carriages, leather, &c.; and beside timber, which is exported chiefly to Great Britain, France, and Holland, has a commerce in iron ware and agricultural produce. About 40,000 tons of shipping are annually employed in its port. It suffered considerably in 1850 and 1857 from conflagrations.

DRAPER, JOHN WILLIAM, an American chemist and physiologist, born near Liverpool,

England, May 5, 1811. He received his early education at the Wesleyan Methodist school at Woodhouse Grove, an institution for the sons of clergymen of that denomination, of which his father was one. Having here acquired the rudiments of knowledge, his maturer education was intrusted to private instructors; and while thus employed, he devoted much attention to chemistry and natural philosophy, a partiality for which he imbibed from his father, who made these pursuits a relaxation from his clerical duties. The higher mathematics were also a part of his early training, and his writings denote their successful cultivation. He subsequently went to the university of London, where he had the opportunity of prosecuting his chemical studies under the late Dr. Turner. Some of Dr. Draper's ancestors had been attracted to America before the revolution, and a greater part of his family connections followed at later periods, and in 1833 he came over to join them. He then continued his chemical and medical studies at the university of Pennsylvania, where he took the degree of M.D. in 1836, and with the rare distinction that his thesis was announced at commencement as having been selected for publication by the medical faculty. A few weeks after, he received the appointment of professor of chemistry, natural philosophy, and physiology in Hampden-Sidney college, Virginia, in which institution he remained until 1839. During his residence there his time was occupied in original chemical and physiological investigations, many of the latter appearing in the "American Journal of Medical Sciences." From Hampden-Sidney college Dr. Draper was called to the chair of chemistry and natural history in the academic department of the university of the city of New York, where, beside instruction in those branches, he has delivered lectures to the advanced undergraduates upon physiology. In 1841 he was appointed professor of chemistry in the university medical college, which forms the medical department of the city university, having coöperated with 5 others (Drs. Valentine Mott, Granville S. Pattison, John W. Revere, Gunning S. Bedford, and Martyn Paine, who were simultaneously elected professors) in establishing that very flourishing school of medicine; and in 1850 physiology was added to the chair of chemistry. These relations to the academic and medical departments of the university have been continued without interruption to the present time; and it is also worthy of remark, as illustrating his industry, that he has acted throughout as the medical faculty's secretary, and since 1850 as their presiding officer. As an instructor, Dr. Draper stands in the very first rank, and to his rich variety of attainments unites all the important elements of a public speaker. Although his researches have been mostly experimental, involving therefore great labor and cost, he has written voluminously and with high reputation. Beside contributions to various other scientific journals, he furnished to the "Edinburgh Philosophical Journal" between the years 1837 and 1857 about 40 treatises, principally on topics previously little understood. He is the author of many literary works, reviews, &c., but for the most part published anonymously; of a "Treatise on the Forces which produce the Organization of Plants" (4to., New York, 1844); of a popular "Text Book on Chemistry" (12mo., New York, 1846), and another on "Natural Philosphy" (8vo., New York, 1847), which consist of excerpts from his courses of lectures. His last and most elaborate work is a treatise on "Human Physiology, Statical and Dynamical; or the Conditions and Course of the Life of Man" (8vo., New York, 1856, and a new edition, 1858).

DRAPER, Sir William, an English officer, born in Bristol in 1721, died in Bath, Jan. 8, 1787. He was educated at Eton and Cambridge, entered the army, won distinction in the East Indies, obtained a colonelcy in 1760, acted as brigadier at the capture of Belle Isle in 1761, and led the land forces at the taking of Manila in 1763. The Spaniards ransomed the latter place by the promise of £1,000,000, which was never paid, and Sir William corresponded long but unprofitably on the subject with his own and the Spanish governments. For his services, however, he was made knight of the bath. When the first of the "Junius" letters appeared in Jan. 1769, he came forward under his own name in defence of his friend the marquis of Granby. Junius replied with marvellous skill and sharpness; two more letters passed on each side, and Sir William then retired from a contest which had endangered his good name, damaged the cause of his friend, and heightened his opponent's reputation. Six months afterward, when he saw these letters republished, he appeared twice again in print to complain of their injustice, and was again worsted by his anonymous antagonist. During the same year he visited America, where he was married to Miss De Lancey of New York. In 1779 he was appointed lieutenant-governor of Minorca, and on the surrender of that island brought 29 charges against the governor, Murray, for all but 2 of which he was obliged to offer an apology.

DRAUGHTS, a game played by 2 persons, on a checkered board like the chess-board, with 12 or 20 pieces on each side, which capture each other by angular movements governed by certain rules, until the game ends by one player losing all his pieces, or by both players getting their pieces into positions from which they cannot be taken. In America the game is commonly called checkers. In France it is known as *le jeu de dames*, in Italy as *dama*, in Germany as *Damen;* all which terms are commonly supposed to have their origin in some fancied adaptation of the game as a pastime for women. But as it has been played in Egypt for more than 4,000 years, and made its appearance in Europe only 3 or 4 centuries ago when there was much intercourse between southern Europe and Alexandria and other Egyptian ports, before the passage to India round the cape of Good

Hope replaced that through the isthmus of Suez, it is probable that the Egyptian-Arabic name of the game, *dameh*, is the source of its appellations in French, Italian, and German. In Polish, the game has, beside that of *dama*, a foreign designation, *arcaby* or *warcaby*, supposed to be of oriental origin. In Spanish, the word *ajedrez*, applied to both chess and draughts, is also of eastern derivation, and appears to be nearly equivalent to the American term checkers.—The origin of the game is uncertain. It is supposed to have preceded chess, and is certainly of very high antiquity, for in Egypt, as appears from the monumental paintings, it was a common amusement in the reigns of the Osirtasens, 2000 B. C. It was played as now with pieces, all of which on the same board were alike in size and form, though on different boards they varied in shape, some being small, others large and rounded at the top or carved into human heads. The kind used by King Rhamses, 1311 B. C., who is represented on the walls of his palace at Thebes playing at draughts with the ladies of his household, resembled small ninepins, and seem to have been about 1½ inches high, standing on a circular base of half an inch in diameter. Some have been found of ivory, 1¾ inches high and 1⅛ in diameter, with a small knob at the top. The opposite sets of pieces were distinguished sometimes by their color and sometimes by their form, one set being black, the other white or red, or one set having round, the other flat tops. It is uncertain how the Egyptians played the game, though from the position of some of the pieces in the paintings it would seem that they did not take backward, as is done in the Polish game of draughts. The modern Egyptians, who use pieces similar to those used by their predecessors, play the game as it is generally played in Europe and America. By the Greeks the invention of draughts, as well as of dice and many other things, was poetically ascribed to Palamedes, one of the heroes of the expedition against Troy, 1193 B. C. Plato, however, attributes the invention to the Egyptian Theuth. Homer, in the 1st book of the Odyssey, describing Minerva's arrival at the palace of Ulysses in Ithaca, says: "There she found the haughty suitors; some of them were amusing themselves before the gates with draughts, sitting upon the hides of oxen which they themselves had slain." There is reason to believe, however, that the game mentioned by the Greek writers was a species of backgammon.—In playing draughts, the board is placed with an upper white corner on the right hand. Each player places his pieces on the 3 lines of squares nearest to him. In England the white squares are played upon; in Scotland and America the black squares are generally selected. The game is begun by each player moving alternately one of his men along the diagonal on which they are first placed, one square at a time to the right or the left. When 2 hostile pieces encounter each other, the one that has the move may take the other, if there be a vacant square of the color played upon behind it, by leaping over the other into that square. The piece leaped over is removed from the board. If several pieces on forward diagonals should be exposed by having alternate open squares behind them, they may all be taken at once, and the taking piece placed on the square behind the last piece captured. When a piece has reached one of the 4 squares of the extreme opposite row, it becomes a king, and is crowned by placing one of the captured pieces upon it. Kings can move backward as well as forward, though only one square at a time. The principal laws of the game are these: if a piece is touched, it must be moved, if a move be possible; the player who has the move must take a piece which is exposed to capture; if he neglects to take it, his adversary may remove from the board the piece with which the capture should have been made; but a player has no right to decline to take under any circumstances. The first move of each game is to be taken by the players in turn; if lots are drawn for the move, he who gains the choice may move first or require his adversary to move. In Polish draughts, a variety of the game played not only in Poland, but in other parts of the continent of Europe, and sometimes in England and America, the pieces are moved forward as in the English form of the game, but in taking they move like the kings of the English game, either backward or forward. The kings in the Polish game have the privilege of passing over several squares at one time, and even over the whole length of the diagonal when no pieces obstruct the move. Polish draughts is sometimes played with 40 pieces on a board divided into 100 squares.—M. Mallet, a celebrated professor of mathematics, published a treatise on draughts at Paris in 1668. Another teacher of mathematics, William Paine, published at London in 1756 an "Introduction to the Game of Draughts." The best work on the subject is the "Guide to the Game of Draughts," by Joshua Sturges (London, 1800), of which an improved edition appeared in 1835, the whole of which, with additions, is comprised in the "Handbook of Games" which forms one of the volumes of "Bohn's Scientific Library" (London, 1850).

DRAVE (Ger. *Drau;* Hung. *Dráva;* anc. *Dravus*), one of the principal tributaries of the Danube, rises from 2 sources situated in the E. portion of the Tyrol. In its upper part it is a small and extremely rapid river, with craggy and overhanging banks, but it becomes navigable at Villach, and flows with a slow current through a low and marshy country, through S. Styria, where it washes the walls of Marburg and Friedau, then along the S. border of Hungary, which it separates from Croatia and Slavonia, till it enters the Danube 14 m. E. from Eszek, as a large and powerful stream, after a course of 360 m. Its navigation above Völkermarkt is obstructed by various falls and cataracts. The most important of its numerous affluents is the Mur, the largest river in Styria. Lienz in Tyrol, Villach, Pettau, Warasdin, and Eszek, are among

the chief towns situated on its banks. One of the most interesting uses of the Drave is that to which the Hungarian peasants put it, who descend it on rafts of empty barrels after having disposed of their wine in the mountains of Carinthia.

DRAWING, the representation or delineation of objects, either as they appear to the eye, or as projected on assumed planes, or as designated by conventional signs having a certain similarity to the appearance of the objects themselves. The painter, with free hand, draws or sketches objects in their visible and natural forms; the mechanical or architectural draughtsman projects, according to certain established rules and principles, objects existing or designed; while from the notes of the surveyor the topographical draughtsman plots the surface of a field or locality, with its natural and artificial objects represented somewhat as they would appear projected on a transparent plane above them, but with certain conventionalities to express more definitely certain features. Architectural and mechanical drawing is in general the delineation of objects by geometric or orthographic projection. Since the surfaces of all bodies may be considered to be composed of points, the first step is to represent the position of a point in space, by referring it to planes whose position is established. In general these planes are assumed at right angles to each other, and the points projected upon them to make up the drawings of the plan, end and side elevation. Let a brick be held flatwise in the corner of a rectangular box, with its sides parallel to the various sides of the box; if now from the several corners of the brick perpendiculars be let fall upon the adjacent sides, the points thus found will be the orthographic projections of the corners; and if these points be connected by corresponding lines, there will be outlines of the brick under 3 views or projections: upon the bottom of the box a rectangle 8 by 4 inches, being the plan of the brick; upon one side a rectangle 8 by $2\frac{1}{2}$ inches, the side elevation; on the other side a rectangle 4 by $2\frac{1}{2}$ inches, the end elevation. If the brick be inclined to either or all of the sides of the box, the projected outlines will be varied; but the same rule for determining the position of points obtains, viz.: by letting fall perpendiculars on the planes to which they are referred. The orthographic projection of any object in outline is the shadow it would cast on a plane perpendicular to the rays of the sun, if held between it and the sun. Simple objects in general may be defined by 2 views, a plan and elevation; but often, to illustrate the construction of the interior, sections are necessary, that is, the appearances that might be presented were the objects cut by planes; all portions that would be thus absolutely cut, are designated by filling up the outline with a quantity of inclined parallel straight lines, at equal intervals from each other; should there be distinct parts in section, in contact with each other, to prevent confusion the different sections are expressed by lines inclined in opposite directions. In most architectural and mechanical constructions it would be obviously impossible that they could be drawn full size. Scales are therefore made use of in which fractional parts represent wholes. The scale in most common use in architectural drawings is that of $\frac{1}{4}$ of an inch to the foot, or $\frac{1}{48}$ of the lineal dimensions; in mechanical drawings, $\frac{1}{4}$ or $\frac{1}{8}$ full size, that is, as usually understood, $\frac{1}{4}$ or $\frac{1}{8}$ of the lineal dimensions. Beside these scales, the divisions of one inch or foot are very numerous, according to the purposes for which the drawing is designed. Working drawings of machines, or those intended to be used in construction, are generally laid off to as large a scale as possible; they are mostly outline drawings, consisting of lines to indicate the form of the object represented. The roundness, fulness, or obliquity of the individual surfaces is not indicated by the lines, although it may be generally inferred from the relation of the different views of the same part. The direct significance of an outline drawing is often considerably increased by strengthening those lines which indicate the contours of surfaces resting in the shadow. That all parts may be shade-lined according to one uniform rule, the light is supposed to fall upon the object obliquely at an angle of 45°, that the horizontal and vertical lines may be relieved equally. In general the light is supposed to fall, as it were, from the upper left hand corner of the paper diagonally, and the same rule is followed in the more finished drawings where both shade and shadow are introduced. As a means of avoiding the indefiniteness presented by mere outline, recourse is had frequently to the mere shading of the parts of a machine or edifice, usually done with color and a brush. In architectural drawings, a complete picture is often attempted with all the appliances of shade and shadow, intended to show the artistic effect of the construction. Color is introduced not unfrequently in both mechanical and architectural drawings, to show the material of which the construction is composed; in these cases it is usual to imitate somewhat the natural color of the substances—wood with burnt sienna, brick with Indian red, wrought iron with Prussian or indigo blue, cast iron with a dark blue tint, shading off to a green. —Beside orthographic projection, architects, for the representation both of exterior and interior of edifices, frequently make use of perspective, and mechanical draughtsmen, for the better understanding of the parts of a machine than by separate plans and elevations, unite them by the rules of isometrical drawing. The science of perspective is the representation by geometrical rules, on a plane surface, of objects as they appear to the eye from an assumed point of view. All the points of the surface of a body are visible by means of luminous rays proceeding from these points to the eye, forming a cone of rays. The intersection of these rays by an intervening transparent plane is the perspective projection

of these points, the rules for the projection of which mechanically are simple and well established. The supposed transparent plane is called the plane of projection or plane of the picture. The horizon of the picture is the horizontal line resulting from the intersection of the plane of the picture by a horizontal plane passing through the eye. Point of view or point of sight is the point where the eye is supposed to be placed. Vanishing points are points in a picture to which all lines converge that are in the object parallel to each other. An object is said to be in parallel perspective when one of its sides is parallel to the plane of the picture—in angular perspective when none of its sides are so. Isometrical drawing implies that the measures of the representations of the lines forming the sides of each face are equal. The principle of isometrical projection consists in selecting for the plane of the projection one equally inclined to 3 principal axes at right angles to each other, so that all straight lines coincident or parallel to these axes are drawn in projection to the same scale. To draw a cube in isometrical projection, with a radius equal to one side of the cube, describe a circle, inscribe a regular hexagon, and connect alternate angles by lines to the centre; the hexagon will be divided into 4 quadrilaterals, each of which will represent a face of the cube; all the lines will be equal, and equal to the side of the cube. On these lines can be set off distances as in orthographic projection, but only upon these lines, or those parallel thereto. Curved or inclined lines are therefore to be established by reference to these lines, and not by direct measure of the lines themselves. Isometrical drawing is especially valuable to the mechanical draughtsman, embracing as it does the applicability of a scale with pictorial representation. In drawings for the patent office it is of very general application.—Topographical drawing is the delineation of the surface of a locality, with the natural and artificial objects, as houses, roads, rivers, hills, &c., upon it, in their relative dimensions and positions; giving as it were in miniature a copy of the field, farm, district, &c., as it would be seen by the eye moving over it. Many of the objects thus to be represented can be defined by regular and mathematical lines, but many other objects, from their irregularity of outline and their insignificance in extent, would be very difficult to distinguish. Certain signs have therefore been adopted into general use among draughtsmen, some of which resemble in some degree the objects for which they stand, while others are purely conventional. Sand is represented by fine dots, gravel by coarser dots; meadow or grass line is represented by tufts of little perpendicular lines; trees, although not consonant with the other parts of the plan, are represented often in elevation, at other times by clumps of foliage in plan, sometimes distinctive in their foliage; dwellings and edifices usually in plan, made distinctive by some small prefix, as a pair of scales for a court house, a sign post for a tavern, a horse shoe for a smithy, a church with a cross or steeple, &c. The localities of mines are represented by the signs of the planets which were anciently associated with various metals, and a black circle or dot for coal. Hills are represented by 2 methods, the vertical and the horizontal. In the first the strokes of the pen follow the course the water would take in running down the slopes, the strokes being made heavier the steeper the inclination; and systems have been proposed and used by which the inclination is defined by the comparative thickness of the line and the intervening spaces. In the system proposed for the U. S. coast survey, slopes of 75° are represented by a proportion of black to white of 9 to 2, and so down by 9 grades to a slope of 2½°, in which the proportion is 1 black to 10 white. By the horizontal method, or by contours, hills are represented by horizontal lines traced round them, such as would be shown on the ground by water rising by equal vertical stages. The choice of a scale for a plot depends in a great measure on the purpose for which the plan is intended. Plans of house lots are usually named as being so many feet to the inch, plots of surveys so many chains to the inch, maps or surveys of states so many miles to the inch, and maps of railway surveys as so many feet to the inch, or so many inches to the mile. In the U. S. coast survey all the scales are expressed fractionally and decimally. The scales of small harbor charts vary from 1 : 5,000 to 1 : 60,000; that of charts of bays and sounds is usually 1 to 80,000, of general coast charts 1 to 400,000. In the U. S. engineer service the following scales are prescribed: general plans of building, 1 : 120; maps of ground with horizontal curves, 1 : 600; topographical maps comprising 1½ miles square, 1 m. to 2 ft., or 1 : 2,640; 3 miles square, 1 : 5,280; between 4 and 8 miles, 1 : 10,560; 9 miles square, 1 : 15,840; not exceeding 24 miles square, 1 : 31,680; 50 miles square, 1 : 63,360; 100 miles square, 1 : 126,720; surveys of roads and canals, 1 : 600. In the plotting of sections, as of railway cuttings, a horizontal or base line is drawn, on which are laid off the stations or distances at which levels have been taken; at these points perpendiculars or ordinates are erected, and upon them are marked the heights of ground above base, and the marks are joined by straight lines. To express rock in a cut, it is generally represented by parallel inclined lines; rivers by horizontal lines, or better colored in blue; the depth of sounding in a mud bottom by a mass of dots. Since it would be in general impossible to express the variations of the surface of the ground in the same scale as that adopted for the plan, it is usual to make the vertical scale larger than that of the horizontal lines in the proportion of 10 or 20 to 1.—Topographical features are represented as effectively by the brush and water colors as by the pen. Colors are used conventionally. Thus in the practice of the French military engineers, woods are represented by yellow, gamboge with a very little

indigo; grass land green, gamboge and indigo; cultivated land brown, lake, gamboge, and a little India ink or burnt sienna; adjoining fields are slightly varied in tint; gardens, by patches of green and brown; uncultivated land, marbled green and light brown; brush, brambles, &c., marbled green and yellow; vineyards, purple; sands, a light brown; lakes and rivers, a light blue; seas, a dark blue, with a little yellow added; roads, brown; hills, greenish brown. In addition to the conventional colors, a sort of imitation of the conventional signs already explained is introduced with the brush, and shadows are almost invariably introduced. Topographical drawings receive the light, the same as architectural and mechanical drawings, from the upper left hand corner. Hills are shaded, not as they would appear in nature, but on the conventional system of making the slopes darker in proportion to their steepness, the summit of the highest ranges being left white. Topographical drawings embrace but a small portion of surface, and are therefore plotted directly from measures; but in geographical maps, embracing at times a great extent of country, various projections are made use of to express as nearly as possible a spherical surface upon a plane. These species of projection are generally included under the head of mapping, and belong to the province of geography.

DRAYTON, Michael, an English poet, born in Hartshill, or Harshull, in the parish of Atherston, Warwickshire, in 1563, died in 1631. His life is involved in obscurity. It is said that he was the son of a butcher, was a page to a person of rank, was maintained for some time at Oxford by Sir Henry Goodere, held a commission in the army, and witnessed the defeat of the Spanish armada; but none of these statements are well supported. In 1626 he was poet laureate. He found patrons in Sir Walter Aston and the earl of Dorset, but he never became wealthy or powerful, though respected for his virtues and talent. It is not easy to discover the order of his various poems, some of which were published without date. The best known is his "Poly-olbion," a descriptive poem on England, her legends, antiquities, and productions, the first 18 books of which were published in 1613, and the whole 30 in 1622. Among his other works are "Harmony of the Church, containing the spiritual Songs and holy Hymns of godly Men, Patriarchs, and Prophets" (4to., 1591, only one copy of which edition is known to exist; and 8vo., London, 1843, edited by Dyce); "Idea, the Shepherd's Garland, and Roland's Sacrifice to the Nine Muses" (4to., 1593), the second of which was reissued under the title of "Pastorals;" "Mortimeriados" (4to., 1596), reprinted under the title of the "Barons' Wars;" "England's Heroical Epistles" (8vo., 1598); the "Legend of Great Cromwell" (4to., 1607); "Battle of Agincourt" (folio, 1627); "Muses' Elysium" (4to., 1630); numerous legends, sonnets, &c., mostly printed in collections; and "Nymphidia, the Court of Fairy," edited by Sir E. Brydges (Kent, 1814). The last is one of his most admirable productions. His historical poems are dignified, full of fine descriptions, and rich in true poetic spirit, and his "Poly-olbion" is moreover so accurate as to be quoted as authority by antiquaries. Notes to the first portion of it were written by Selden. He was buried in Westminster abbey, where a monument was erected to his memory. An edition of his works, with a historical essay on his life and writings, was published in 1752–'3 (4 vols. 8vo., London).

DRAYTON, William, LL.D., an American judge, born in the province of South Carolina in 1733, died in June, 1790. He was educated for the bar in the Middle Temple, London, where he studied 4 years. He returned to America in 1754, and was appointed chief justice in the province of East Florida in 1768. During the war of the revolution he was suspended from his office and reinstated in it, and went with his family for a time to England. After the peace he became successively judge of the admiralty court of South Carolina, associate justice of the state, and a judge under the federal government.

DRAYTON, William, an American politician, a native of South Carolina, died in Philadelphia, May 24, 1846. Though a federalist in 1812, he held a commission in the army after the declaration of war. He was a representative in congress from South Carolina from 1825 to 1833, and in 1830 was a leader of the union party in opposition to that of nullification. He resided in Philadelphia many years prior to his death, and in 1839 succeeded Nicholas Biddle as president of the U. S. bank, the affairs of which he found it impossible to retrieve.

DRAYTON, William Henry, an American statesman of the period of the revolution, born at Drayton hall, on Ashley river, S. C., in Sept. 1742, died in Philadelphia in Sept. 1779. He belonged to an influential family of South Carolina, and was educated in England at Westminster school, and at Baliol college, Oxford. Returning to America in 1764, he became an active writer on political affairs. In 1769 he published letters on the side of the government, which brought him into controversy with Christopher Gadsden and other patriotic leaders. In 1771, after revisiting England, he was appointed privy councillor for the province of South Carolina; but as the revolutionary crisis approached he espoused the popular cause, and protested against the proceedings of his colleagues. In 1774 he was appointed judge of the province, and when the continental congress was about to sit he published a pamphlet under the signature of "A Freeman," which substantially marked out the line of conduct pursued by the congress. Suspended from his offices under the crown, he was made a member of the popular committee of safety, and was prominent in advising the seizure of the provincial arsenals and British mails. In 1775 he was president of the provincial congress, and in 1776 was elected chief justice of South Carolina. He soon after de-

livered an energetic charge to the grand jury on the question of independence, which was published throughout the colonies and had great influence. He had produced several other political charges and pamphlets, when in 1778 he was elected a delegate to the continental congress, of which he was a prominent member till his death. He left a minute narrative of the preliminary and current events of the revolution, which was prepared for the press and published by his son, Gov. John Drayton (2 vols. 8vo., Charleston, 1821).

DREAM, the series of thoughts which occupy the mind during sleep. The whole animal kingdom is characterized in its sensuous relations with the external world by two distinct, and, so far as the organs involving these relations are concerned, opposite conditions, the one of wakefulness, and the other of sleep. Within certain limits this alternation of action and repose presents itself as a general law of animal organization, more or less varied, according to the simpleness or complexity of the functions involved; and hence it is found that the quantity and regularity of sleep bear a close relation to the degree of development of animal life. To those vertebrata in which the muscular and nervous tissues exist in their most complete conditions, sleep is much more important than to those types of organic existence which, while endowed with some of the functions of animal organization, are for the most part devoted to the simple process of assimilation. Indeed, a point is at last reached where no evidence of the phenomenon of sleep is presented. In man, in whom the voluntary and involuntary functions exist in their most complete development, and in whom their operations are complicated by the addition of those of the intellect, the periods of waking and repose are most fully marked, and their presence most important to the welfare of the individual. In sleep, the organs of sense, the power of voluntary motion, and the active powers of the mind suspend in a great degree their operation, in order to collect by rest new strength. The approach of sleep is announced by diminished activity of mind and loss of the power of attention. The senses become blunted to external impressions, and we feel an unconquerable desire for stillness and repose. Our ideas grow confused, our sensations obscure, our sight fails, hearing grows dull and uncertain, the eyelids close, the joints relax, and the body instinctively assumes an easy position. The vital activity, however, is in full vigor; the functions of the heart and the lungs, breathing and the circulation of the blood, continue, but are more calm and equable than during the waking season; the nutrition of the system, the secretion and absorption of the juices, are also carried on undisturbedly and perfectly. Hence sleep is not really a state of total inactivity, and only bears a very partial resemblance to death. A person awaking from profound sleep finds himself refreshed, and his bodily and intellectual functions restored to their usual vigor. If the sleep, however, be partial and disturbed, these results do not follow, but the waking state is accompanied by a sense of lassitude and fatigue. It is in this latter condition that dreams take place, and hence Dugald Stewart has properly defined dreaming to be that condition of sleep in which we have nearly or quite lost all volition over the bodily organs, but in which those mental powers necessary for volition retain a partial degree of activity. M. Perquin observed in the hospital of Montpellier in 1821 a case which throws considerable light upon the actual condition of the brain in profound sleep, and in that in which dreams occur. A female aged 26 had lost a portion of her scalp, skull bone, and dura mater, under an attack of malignant disease, by means of which a portion of the brain was exposed in such a manner as admitted of inspection. When this patient was in a dreamless state, or in profound sleep, her brain was motionless, and lay within the cranium. When the sleep was imperfect, and the mind was agitated by dreams, her brain moved and protruded from the cranium, forming a cerebral hernia. This protrusion was still greater whenever the dreams, as reported by herself, were most active, and when she was perfectly awake, especially if engaged in active or sprightly conversation, it attained its fullest development; nor did this protrusion occur in jerks, alternating with recessions, as if caused by arterial blood, but remained permanent while the conversation continued. It is clearly shown by this case, so far as the appearance of the brain is concerned, that during profound sleep the active state of the mental faculty ceases, but that, in that condition in which dreams occur, some of the mental powers are sufficiently active to excite a motion in the cerebral organs, less in degree than in a state of full wakefulness, but more than in a condition of profound sleep. Though the power of volition does not seem to be altogether absent in sleep, the will appears to lose its influence over those faculties of the mind and members of the body which during our waking hours are subject to its authority. Hence it may be inferred that all our mental operations which are independent of the will continue during sleep. The senses may be considered as the media by means of which the spirit within is brought in contact with the external world, and comes to have a knowledge of actual existence. Although the predisposing causes of dreams may be diverse, yet they are generally referable to some peculiar condition of the body, and are often called into action through the agency of the external senses. Dr. Gregory relates that, having occasion to apply a bottle of hot water to his feet upon retiring for the night, he dreamed that he was making a journey to Mount Etna, and found the heat insufferable. Dr. Reid, having had a blister applied to his head, dreamed that he was scalped by a party of Indians. M. Giron de Buzereingues made a series of experiments to test how far he could determine his

dreams at will by operating upon the mind through the medium of the senses. With this view he left his knees uncovered on falling asleep, and dreamed that he was travelling at night in a diligence with a vivid impression of cold knees produced by the rigor of the weather. Waller relates the case of a gentleman who was ever after a victim to terror on account of a dream, which he could never look upon except as a real occurrence. He was lying in bed, and as he imagined quite awake, when he felt the distinct impression of a hand placed upon his shoulder, which produced such a state of alarm that he durst not move in bed. The shoulder which had experienced the impression had been uncovered, and the cold to which it was exposed produced the sensation. Persons in whom one of the senses is defective frequently have their dreams modified by this circumstance. Darwin relates the case of a deaf gentleman who in his dreams always appeared to converse by means of the fingers or in writing. He never had the impression of hearing speech, and for the same reason one who has been blind from his birth never dreams of visible objects. Sensations produced by the condition of the digestive apparatus have a very marked influence on the phenomena of dreams. When the functions of the digestive organs are properly performed, the dreams, if affected at all from this cause, are pleasant in their character; if however there exists any disturbance in this part of the system, the dreams are apt to assume a painful character, usually proportioned in intensity to the amount of disturbance of the alimentary canal. To this class of sensations may be referred those dreams produced by the use of opium and intoxicating drinks, which in part at least act by the impression made upon the digestive organs. Dreams induced by this latter cause are remarkable for the extravagance of the phantasmagoria they exhibit, frequently presenting shapes of the most fugitive and fanciful character. The dreamer often seems endowed with such elasticity that it appears as if he could easily mount to and float upon the clouds above him. De Quincey, in the "Confessions of an Opium Eater," has portrayed in the most vivid manner the effect of that narcotic in the production of dreams. "Under the connecting feeling of tropical heat and vertical sunlights I brought together all creatures, birds, beasts, reptiles, all trees and plants, usages and appearances, that are found in all tropical regions, and assembled them together in China and Hindostan. From kindred feelings I soon brought Egypt and all her gods under the same law. I was stared at, hooted at, grinned at, chattered at by monkeys, by parroquets, by cockatoos. I ran into pagodas, and was fixed for centuries at the summit or in the secret rooms. I was the idol, I was the priest. I was worshipped, I was sacrificed. I fled from the wrath of Brahma through all the forests of Asia. Vishnu hated me, Seeva lay in wait for me. I came suddenly upon Isis and Osiris. I had done a deed, they said, at which the ibis and the crocodile trembled. I was buried for 1,000 years in stone coffins with mummies and sphinxes, in narrow chambers at the heart of eternal pyramids. I was kissed with cancerous kisses by crocodiles, and lay confounded with unutterable slimy things among reeds and Nilotic mud." In these hallucinations it will be observed how completely all ordinary ideas of time and space are annihilated. Indeed, De Quincey, in noticing this curious psychological phenomenon, says: "The sense of space, and in the end the sense of time, were both powerfully affected. Buildings, landscapes, &c., were exhibited in proportions so vast as the bodily eye is not fitted to receive. Space swelled and was amplified to an extent of unutterable infinity. This, however, did not disturb me so much as the expansion of time. I sometimes seemed to have lived for 70 or 100 years in a single night." Nor does it require the aid of a narcotic as powerful as opium, or indeed any thing beyond what ordinarily occurs in a state of dreaming, to create ideas of time and space apparently as incongruous as those narrated by the opium eater. The sleeper who is suddenly awakened by a loud rap does not begin and terminate his dream with this simple occurrence, but experiences a long train of events requiring hours and even days for their fulfilment, and which are all evidently occasioned by the sound which awakens him, and concentrated within the brief space of time it occupies. A person who was suddenly aroused from sleep by a few drops of water sprinkled in his face, dreamed of the events of an entire life in which happiness and sorrow were mingled, and which finally terminated with an altercation upon the borders of an extensive lake, into which his exasperated companion, after a considerable struggle, succeeded in plunging him. It is evident that the association of ideas in this case which produced the lake, the altercation, and the sudden plunge, was occasioned by the water sprinkled upon the face, and the presumption is probable that the whole machinery of an entire life was due to the same cause. Dr. Abercrombie relates a similar case of a gentleman who dreamed that he had enlisted as a soldier, joined his regiment, deserted, was apprehended, carried back, tried, condemned to be shot, and was at last led out to execution. After the usual preparations a gun was fired, and he awoke with the report to discover that the cause of his disturbance was a noise in the adjacent room. Dreams are often produced by the waking associations which precede them; thus the writer had occasion to send a letter to a relative in a neighboring city, and upon retiring to rest dreamed that he was walking in the principal thoroughfare of the city where his correspondent resided, and accidentally meeting him, held a long conversation, upon subjects, however, in no way connected with the one which gave rise to the correspondence. So, too, dreams may be characteristic of the peculiar idiosyncrasies of the dreamers: a miser will dream of his gold, a

philosopher of science, a merchant of his ventures, the musician of melody, and the lover of his mistress. Tartinia, a distinguished violin player, is said to have composed his "Devil's Sonata" under the inspiration of a dream, in which the devil appeared to him and invited him to a trial of skill upon his own instrument, which he accepted, and awoke with the music of the sonata so vividly impressed upon his mind that he had no difficulty in committing it to paper. In like manner Coleridge composed his poem "Kubla Khan" in a dream, of which the following is his account: "In the summer of 1797 the author, then in ill health, had retired to a lonely farm house between Porlock and Linton, on the Exmoor confines of Somerset and Devonshire. In consequence of a slight indisposition an anodyne had been prescribed, from the effects of which he fell asleep in his chair at the moment he was reading the following sentence, or words of the same substance, in Purchas's 'Pilgrimage': 'Here the Khan Kubla commanded a palace to be built and a stately garden thereunto, and thus 10 miles of fertile ground were enclosed within a wall.'" Coleridge continued for about 3 hours apparently in a profound sleep, during which he had the most vivid impression that he had composed between 200 and 300 lines. On awaking he had so distinct a remembrance of the whole that he seized his pen and wrote down the lines which are still preserved. Unfortunately, at this moment he was called out of the room to attend to some business which occupied more than an hour. Upon his return he found to his surprise and chagrin that, although some vague idea of the vision was still present, yet, with the exception of some 8 or 10 scattered and fragmentary lines and images, the whole had been obliterated from his memory. Instances like the above occasionally occur where the mind in a state of waking is aided by the processes carried on during sleep, but these are rare. As a general rule dreams are wanting in coherence and unsubstantial in reasoning. Nothing is more common than for the mind in dreams to blend together objects and events which could not have an associated existence in reality. The faces of friends long since dead and events long since past rise before the mind with all the vividness of real existence, and fail to excite surprise by their incongruity because the mind views them without the association of ideas which in a waking state would place them at such a distance from the present that no cognizance could be taken of them except as very remote events. It is the absence of these associated ideas, which in a state of wakefulness fix the limits as to time and space of each fact of which the mind has a knowledge, that prevents any surprise at the occurrence of unusual events in dreams, and constitutes one of their most remarkable features. The popular belief that in dreams an insight is frequently given of coming events is shared by many well-informed persons, and is supposed to be corroborated by many remarkable cases; from among them the following is selected. Mr. D., residing in Edinburgh, informed his aunt one evening of his intention to join a sailing party the next morning upon the firth of Forth. The lady retired to rest and dreamed repeatedly of seeing a boat sink and those on board drowning. When wakened she went to the bedside of her nephew, and with great difficulty obtained his promise to remain at home. In the afternoon a violent storm arose, the boat was upset, and all that were in it went to the bottom.—The earliest mention of dreams is in the Scriptures and in the poems of Homer, in both of which a supernatural origin is generally ascribed to them. By the ancients, indeed, dreams were almost universally regarded as coming from the other world, and from both good and evil sources. A great number of instances are on record in the Greek and Latin classics of remarkable dreams, which show how widely the faith in the spiritual nature of dreaming was disseminated. The night before the assassination of Julius Cæsar, his wife Calphurnia dreamed that her husband fell bleeding across her knees. On the night that Attila died, the emperor Marcian at Constantinople dreamed that he saw the bow of the Hunnish conqueror broken asunder. Cicero relates a story of two Arcadians, who, travelling together, arrived at Megara and went to separate lodgings, one of them to an inn, the other to a private house. In the course of the night the latter dreamed that his friend appeared to him and begged for help because the innkeeper was preparing to murder him. The dreamer awoke, but not considering the matter worthy of attention, went to sleep again. A second time his friend appeared, telling him that assistance would be too late, for the murder had already been committed. The murdered person also stated that his body had been put into a cart and covered with manure, and that an attempt would be made to take it out of the city the next morning. The dreamer awoke, went to the magistrates, had the cart searched, when the body was found and the murderer brought to justice. Dreams were even allowed to influence legislation. During the Marsian war (90 B. C.) the Roman senate ordered the temple of Juno Sospita to be rebuilt in consequence of a dream of Cecelia Metella, the wife of the consul Appius Claudius Pulcher. Some of the fathers of the Christian church attached considerable importance to dreams. Tertullian thought they came from God as one species of prophecy, though many dreams may be attributed to the agency of demons. He believed that future honors and dignities, medical remedies, thefts, and treasures had been occasionally revealed by dreams. St. Augustine relates a dream by which Gennadius, a Carthaginian physician, was convinced of the immortality of the soul, by the apparition to him in his sleep of a young man, who reasoned with him on the subject, and argued that as he could see when his bodily eyes were closed in sleep, so

he would find that when his bodily senses were extinct in death he would see and hear and feel with the senses of his spirit.

DREBBEL, Cornelis van, a Dutch philosopher and inventor, born in Alkmaar in North Holland in 1572, died in London in 1634. His inventive faculty raised him from a peasant boy to the favor of the emperors Rudolph II. and Ferdinand II., and of James I. of England. He lived in London from the year 1620, devoted entirely to scientific labors. Numerous marvels are related of him, but it is only certain that he possessed extraordinary knowledge of the principles of optics and mechanics. He invented several philosophical instruments, among which, it is said, were the compound microscope and a thermometer consisting of a glass tube containing water connected with a bulb containing air. His contemporaries say that he displayed to King James a glass globe in which by means of the 4 elements he had produced perpetual motion, and that by means of machinery he imitated rain, thunder, lightning, and cold, and was able quickly to exhaust a river or lake. He discovered a bright scarlet dye for woollens and silks, which was introduced into France by the founders of the Gobelin manufactures; and the invention of the telescope has been ascribed to him, but on no good grounds. Drebbel left 2 treatises which appeared first in Dutch (Leyden, 1608); afterward in Latin, under the title *Tractatus duo: De Natura Elementorum; De Quinta Essentia* (Hamburg, 1621); and again in French (Paris, 1673).

DREDGING, the process of deepening harbors and channels by excavating the sediment that collects in them; the term is also applied to the scooping up of oysters, or any thing else, from the bottom. The force of running water has sometimes been applied to wash out the sediment by which channels become choked; and to render this more efficient, the drainage waters and even the ebb tide have, in places adapted for this operation, been held back by floodgates, and the waters at last let out have rushed with great violence through the channels, sweeping forward the materials that obstructed them. This is the principle of flashing or flushing applied to sewers, &c., and is without question the most efficient mode of dredging in the few situations favorably formed for its application. In the artificial improvements introduced into some of the harbors in England, scouring basins have been constructed especially for this purpose, as for instance at Ramsgate, Dover, &c. To loosen the sediments, so that they might be more easily swept out by the tide or by sluices, the Dutch long since contrived a floating frame to which bars were attached, that went down to the bottom and stirred up the mud, as the machine moved along with the current. These are perhaps the oldest dredging machines. Variously formed scoops have been in use in different places, which as they are drawn over the bottom rake up the sediment as with a hoe, and gather it in the hollow part of the scoop or in a bag of leather attached to the instrument, from which it is discharged when the whole is hoisted to the surface by the rope attached to the scoop. The apparatus is made more efficient by being constructed of large size and worked by a steam engine. A hull is then provided for the machinery, and a scow is employed alongside to receive the mud as it is raised and dumped. Instead of the single large scoop, a line of buckets has been substituted, working around pulleys at the ends of a long frame, which lies over the side of the hull, and one end of which can be lowered down to the bottom or hoisted up when not in use. The buckets, as they pass down empty, suspended on the chain, scoop into the bottom and become filled, and, coming up on the upper side of the frame, discharge themselves as they turn over its higher extremity. The mud falls into troughs, which convey it into the scow alongside. As the channel is deepened, the lower end of the frame is let down accordingly; or if any obstruction impedes the motion of the buckets, this end of the frame is lifted by the pulley, till the chain moves on again. The machine has been made with a frame on each side of the hull, and both kept in operation together.—In another dredging machine the excavator is a wheel about 24 feet in diameter, very strongly braced with many arms, and set in a well hole about 3 feet wide and 26 feet long across the forward part of the hull. It works in boxes which can be raised or lowered by chains and windlass as the depth of water requires. Upon its periphery are the scooping buckets, which are provided with a hinged bottom secured by a latch. As each bucket in the revolution of the wheel approaches the top, it lifts the upper end of a small discharge trough, which falling back causes the bottom of the bucket to be unlatched and its contents to drop out. These are received by the small trough, and immediately pass through it into the larger one that conveys them to the scow. The hull is drawn forward by the steam engine at the precise rate required by the progress of the excavation. It is stated that 1,200 cubic yards of gravel bottom have been dug in a day with a 24-foot wheel provided with 4 buckets.—Dredging for oysters, &c., is performed with an iron rake or scoop at the end of a long pole, and furnished also with a rope by which it is drawn forward. One man pushes the dredge down by the pole, and another draws it along the bottom and raises it into the boat with what it has gathered. For deep water the handle is dispensed with, and the dredge is made like a basket of iron rods, so shaped as to fill itself when dragged upon the bottom. Naturalists make use of dredges of much better construction for collecting specimens of shellfish, &c., from the bottom of the sea. A figure of a small one is given by Woodward in his "Manual of the Mollusca," which is highly recommended for general use. It is a sort of box of 2 strips of boiler plate iron 2 feet long and each 2 inches wide, fastened at their ends to 2 iron rods of

about ¾ inch diameter and 8 inches long. Each end of the rods is bent over at an angle of 145°, and drawn out to a point. The sides placed upon these consequently flare outward, their lower edges coming within 4 inches of each other. These edges are pierced with holes by which the bag is attached in which the materials are gathered up. The part of this bag in contact with the dredge is a network of cod line; the remainder is of raw hide. The net is to allow the escape of the water. The handles are forked iron rods, the double ends securely hooked round the rods that form the ends of the machine, and the single ends provided with rings, meeting in the centre of the box as they are folded down when not in use. The rings are for attaching the towing line to the dredge. With machines of similar construction, but much larger than the one described, the bottom of the sea has been extensively explored by English naturalists off the coasts of Great Britain and Norway. In dredging on coral ground, Mr. Cuming, according to Woodward, employed a 3-inch hawser, and had a patent buoy attached to the dredge by a 1¼-inch rope. Whenever the hawser parts, the buoy and smaller rope secure the recovery of the dredge. In water of 50 to 300 fathoms the dredging can be done only in moderate weather. As the vessel lies to, the dredge is thrown over to windward and is dragged along as she drifts off, spare line being given out as necessary. It is hauled up by block and tackle, or if it get foul, the rope is passed into the boat, which is run out over the dredge and trips it. The contents of the dredge are washed and sifted with 2 copper wire sieves, one "¼ inch," the other very fine. The sediments of the fine sieve are kept for examination for minute shells. Prof. Edward Forbes prepared a form of "dredging papers," which are employed for recording the names and number of species obtained, the depth, locality, nature of the bottom (ground), and whether the specimens are living or dead. The latter are often found in deeper waters than the living individuals. The following directions are given for treating the shellfish obtained by dredging. They should be at once boiled, and the animal removed unless wanted for examination. The bivalves gape, and require to be tied with cotton; the opercula of the univalves should be secured in their apertures with wool. The small univalves may be put up in spirit or glycerine to save time. In warm climates flies and ants assist in removing the animal matter from the spiral shells. Chloride of lime may be employed to deodorize them. Full instructions for collecting and preserving shells may be found in the *Journal de conchyliologie* for 1850, p. 215, and 1851, pp. 182, 226.

DRELINCOURT, Charles, a French Protestant divine, born in Sedan, July 10, 1595, died in Paris, Nov. 3, 1669. He pursued his studies in his native town and in Saumur, preached for 2 years near Langres, and in 1620 became pastor at Charenton, near Paris. He soon distinguished himself as a preacher, being one of the first of the reformed ministry who treated their texts in a practical light, instead of discussing them in the doctrinal and abstract way proper to a theological seminary. Some of his writings, especially his book of "Consolations against the Fear of Death," which has been translated into English and German, are still in use as books of devotion. It was to promote the sale of the English translation of this work that De Foe wrote his celebrated fictitious account of the apparition of Mrs. Veal, who came from the other world on purpose to recommend the perusal of "Drelincourt on Death."

DRENTHE, the poorest and least populous province of the Netherlands, bounded E. by Hanover, N. by Groningen, W. by Friesland, and S. by Overyssel; area, 1,029 sq. m.; pop. in 1858, 94,080. A considerable part of the province is occupied with marshes, heaths, and sand banks, but it yields in sufficient quantities buckwheat and potatoes, upon which the inhabitants subsist almost exclusively. The chief wealth of Drenthe consists in its horses, cattle, sheep, and poultry, all of which are esteemed of superior quality. It has manufactories of woollen fabrics, and its trade is facilitated by a canal from Assen to the Zuyder Zee. The principal rivers are the Vecht, Hunse, and Aa. The chief places are Assen, the capital (pop. about 2,500), Meppel (pop. 6,500), and Coevorden (pop. 2,500).

DRESDEN, the capital of the kingdom of Saxony and of a circle of its own name, situated on both banks of the Elbe, in a fertile valley, noted as the richest wine district of Saxony, and in the vicinity of a picturesque country celebrated under the name of the Saxon Switzerland; lat. 51° 6′ N., long. 13° 44′ E.; 116 m. by railway S. E. from Berlin, and 72 m. E. from Leipsic; pop. of the circle in 1855, 535,531, of whom 525,202 were Lutherans; of the city, including the garrison, 108,732. Steamboats here navigate the Elbe, and 5 railways connect the city with Berlin, Leipsic, Breslau, Prague, and Tharandt—the last to be continued to Freiberg. Dresden seems to have been originally a village of Wendish fishermen, and nearly 500 Wends still form a part of the population. As early as 1216 it was mentioned as a city, and in 1539, when Henry the Pious introduced the reformed religion, it had already passed through many vicissitudes, of which the great fire of 1491 was the most disastrous. After the fire a new town arose, which was fortified by George the Bearded in 1520–'28, and by Maurice the Elector in 1545, and embellished by all succeeding sovereigns, especially by Augustus II. and III., kings of Poland and electors of Saxony, who formed the famous picture gallery which is now one of the greatest attractions of the city. In the 17th and 18th centuries, especially during the 7 years' war, the city was afflicted by pestilence, famine, and the worst calamities of warfare; and it had to undergo a

still more severe trial at the beginning of the present century as the head-quarters alternately of Napoleon and of the Russian and Prussian army. The memorable battle of Dresden, in which Napoleon finally achieved a brilliant but bloody victory over the allies, took place Aug. 24–27, 1813, under the walls of the town. In 1830 we find the city convulsed by a local revolution, the people insisting upon municipal reform, which was granted by the charter of Sept. 4, 1831. The revolution of 1849 also proved disastrous to Dresden. The opera house and a part of the Zwinger were then burned, and other damage was inflicted upon the town. From all this, however, Dresden has since fully recovered. The whole aspect of the city bears the impress of an ancient and thorough civilization. It is surrounded by promenades, pleasure grounds, &c., and consists of 3 portions: the Altstadt, or old town, with its 3 suburbs; the Friedrichstadt, separated from the former by the Weisseritz brook; and the Neustadt, or new town, on the right or N. bank of the Elbe, connected with the other divisions by 2 fine bridges, one of which, 420 feet long, with 16 arches, received from Jean Paul Richter the name of "Dresden's triumphal arch;" the other, the "bridge of Mary," completed in 1852, is crossed by the railway to Prague. There are about 20 churches, some of great beauty, as for instance, the Frauen-Kirche and Sophien-Kirche for Protestants, and a church for Roman Catholics built after a design of Gaetano Chiaveri, with a famous organ, 50 statues of saints by Mattielli, a great altarpiece by Rafael Mengs, and other works of art. The Jews worship in a magnificent synagogue, and religious service in the Wendish language is held in the Kreuz-Kirche for the benefit of the Wendish residents of the city. The educational institutions of Dresden attract many students from foreign lands. In addition to the military academies, polytechnic institute, and medical institutions, there are 14 public schools, with a staff of about 200 teachers, including a gymnasium, 2 primary schools, 4 district schools, 4 local schools, 4 free schools for the poor, beside the seminaries connected with religious denominations, of which the Protestants have over 70. A reformatory institute for children, or ragged school, was founded in 1828, while at the same time a missionary enterprise to prevent crime among children was set on foot by the Pestalozzi association (*Pestalozzistift*). Foremost in beneficent influences among the many charitable institutions of Dresden are the *Frauenverein*, or association of ladies; the *Verein für Rath and That* (a society for dispensing advice and assistance); the *Verein für's Leben* (a society for supplying means of subsistence), which was founded in 1848; and the *Suppenhaus* (soup house), established in 1851. Commercial and industrial activity is not great in Dresden, Leipsic and the manufacturing districts almost monopolizing the trade of the country. The capital, however, presents a fair array of establishments in various branches of industry, its chief manufactures being glass, porcelain, earthenware, mirrors, mathematical and musical instruments, jewelry, gloves, silks, laces, gold and silver thread, painters' colors, white lead, soap, maccaroni, leather, carpets, cotton goods, and straw hats. It has also distilleries, breweries, a sugar refinery, a bell foundery, and a bomb and cannon foundery. The growing trade in cereals called for the establishment of a corn exchange in 1850. The fine chinaware which takes its name from Dresden is not made here, but in the neighboring town of Meissen. There are 3 associations for the promotion of trade and industry, 5 for various branches of science, and many other educational and humanitarian associations. About 26 newspapers and magazines are published there. Beside the many musical associations which have contributed powerfully in promoting the art and love of music in Germany, the city possesses a musical school in the Catholic or royal church, in which high mass is celebrated every Sunday, accompanied by an orchestra from the opera, led by the first masters of the art. Italian opera was predominant at Dresden until 1817, when the compositions of Weber and the performances of Madame Schröder-Devrient inaugurated a new and prosperous era for the German opera. The Dresden theatre is one of the most beautiful of Germany. The city has 27 public squares and a great number of splendid monuments. The railway depots are, as usual in Germany, buildings of great magnificence. Dresden has many superb palaces, especially the Brühl palace, formerly belonging to the minister of that name, afterward used as a residence by Napoleon, and since 1857 as that of the dowager queen Marie. Its chief beauty lies in the pleasure ground on its rear, which is called Brühl's terrace, and is the most fashionable and attractive public park of Dresden. Another favorite resort is the park adjoining the Japanese palace, so called from some oriental figures which adorn it, and occasionally called *Augusteum*, in commemoration of Augustus II., who originally laid it out. The academy of fine arts has been in operation since 1764, and consists of 3 different sections and a school for architects, which was added to it in 1819. The Japanese palace contains the museum of antiquities, occupying 10 saloons, a cabinet of coins, a porcelain cabinet containing more than 60,000 pieces of china, and the public library, consisting of about 300,000 volumes, 2,800 MSS., 20,000 geographical maps, 182,000 pamphlets, &c. Beside this and many private libraries, there is a library of 20,000 volumes in the palace of the princes, where there is also a cabinet of engravings, of porcelains, and of pictures. The Zwinger, a group of buildings surrounding an enclosure planted with orange trees and erected by Augustus II. as a vestibule to a new palace, contain the historical museum, formerly called the armory, celebrated for its splendid array of armor, and the cabinet of natural history. In the same building is a collection of mathemati-

cal and scientific instruments. In the chapel of the royal palace are paintings by Rembrandt, N. Poussin, A. Carracci, and Reni, while the throne room is embellished with large fresco paintings by Bendemann. Opening upon the yard of the royal palace is the celebrated green vault (*Das grüne Gewölbe*), containing an immense collection of precious stones, pearls, and works of art in gold, silver, amber, and ivory, which are arranged in 8 apartments, each exceeding the previous one in the richness of its contents. Their value is said to be over $5,000,000. The picture gallery, however, is the gem of the city. The present handsome red sandstone building, begun in 1846 and opened in 1855, forms one side of the Zwinger, and contains over 1,500 paintings, among which are Raphael's "Madonna di San Sisto," Correggio's "Night," Andrea del Sarto's "Sacrifice of Abraham," Leonardo da Vinci's "Francesco Sforza," 5 paintings of Titian, 14 of Rubens, 21 of Vandyke, and many celebrated works of Italian, Flemish, Dutch, French, and German masters of the ancient and modern schools. The best German work of art is Hans Holbein's "Virgin," and the best French are Claude Lorraine's landscapes. In the same building is the collection of plaster casts made by Rafael Mengs of statues of antiquity, and of the Elgin marbles in the British museum. Forming a supplement to the picture gallery is the collection of engravings, containing works of art of the highest value. It comprises about 300,000 plates, and is considered the finest collection of copperplates in Europe. In the 2d story of the Brühl palace are 6 pieces of tapestry executed after designs by Raphael, and a collection of 50 landscapes by Canaletto. Dresden is chiefly indebted to its art treasures for the high reputation which it enjoys at home and abroad, and for the name of the "Florence of Germany" which was conferred upon it by Herder. (See Lindau, *Geschichte der Stadt Dresden*, 1857.)

DREUX (anc. *Durocasis*, or *Durocasses*), a town of France, department of Eure-et-Loir, on the Blaise near its junction with the Eure, 20 m. N. N. W. from Chartres; pop. in 1856, 6,187. It has grain markets and tanneries, but little other trading or manufacturing industry. The beautiful chapel built to serve as the mausoleum of the Orleans family occupies the site of the church of St. Stephen, erected in 1142, and demolished in 1793. Dreux was captured and burned by the English in 1188, and again taken by them in 1424. In 1562 the Catholic army of Charles IX. and the Protestants under the prince of Condé fought in its neighborhood a very bloody battle, in which Condé was defeated and taken prisoner. Henry IV. of France took it in 1593 after an obstinate siege, since which it has been of less political importance.

DREW, a S. E. co. of Ark., drained by Bartholomew bayou; area, about 900 sq. m.; pop. in 1854, 4,337, of whom 1,541 were slaves. It has a nearly level surface, and a fertile soil. A great part of the land is covered by forests of cypress, ash, &c. The staple productions are cotton, grain, sweet potatoes, and grass, and in 1854 the county yielded 3,731 bales of cotton, 137,970 bushels of Indian corn, and 12,470 of oats. Capital, Monticello.

DREW, Samuel, a Methodist divine, born in the parish of St. Austell, Cornwall, England, March 3, 1765, died March 29, 1833. At the age of 10 he was apprenticed to a shoemaker, and while engaged in learning his trade he learned to read. One of the first books that attracted his attention was Locke's "Essay." Next he read Franklin's "Way to Wealth." In 1787 he commenced business on his own account, and made an attempt to study astronomy, but was not able to advance in that science in consequence of his ignorance of mathematics. His attention was next directed to the study of natural history, but not being able to obtain the requisite books he abandoned it, and resolved to devote his attention to mental philosophy. His first publication was an answer to Paine's "Age of Reason" (1798), which at once brought him into notice. His next work was an "Essay on the Immateriality and Immortality of the Soul" (8vo., 1802), which had passed through 8 editions in 1848, and has been translated into French. Then followed a work on the "Identity and General Resurrection of the Human Body" (8vo., 1809), and another on the "Being and Perfections of God" (2 vols. 8vo.). In his 24th year he became a local preacher among the Wesleyan Methodists. He was a man, in the language of Dr. Adam Clarke, "of primitive simplicity of manners, amiableness of disposition, piety toward God and benevolence to men, seldom to be equalled; and for reach of thought, keenness of discrimination, purity of language, and manly eloquence, not to be surpassed in any of the common walks of life." His last literary production was a "Life of Dr. Coke," written in 1817.

DROGHEDA, a town and port of Ireland, in the province of Leinster, counties of Meath and Louth, on the river Boyne, 4 m. from its mouth, and 32 m. N. from Dublin, by rail; pop. in 1851, 16,845. It was for a long time strongly fortified, and from an early period till about the close of the 17th century was always regarded as a post of great importance by the English. It was for three centuries the principal rendezvous of the numerous troops marched by government against the refractory and rebellious chieftains of Ulster and Leinster. It was gallantly defended in the civil wars of 1641 against a large besieging force under Sir Phelim O'Neill. It was stormed by Cromwell in 1649, and on account of the carnage then inflicted the name of the great protector is still abhorred by the inhabitants. In 1690 the town held out against the troops of King William III. until after the victory achieved by them at the famous battle of the Boyne, fought 2 miles from its walls, and which is commemorated by an obelisk 150 feet high raised upon the very spot where the aged Schomberg fell. Few of the

ancient fortifications of the town remain. The only perfect specimen is the St. Lawrence gate, consisting of 2 lofty round towers with the low gateway between. The Magdalen's steeple, a square structure of elegant proportions, is all that remains of a Dominican convent founded in 1224. Among many other ruins of old religious institutions are those of a Carmelite convent, and of a hospital of the knights of St. John of Jerusalem. The town is now the seat of extensive cotton and linen manufactories, tanneries, and breweries, and has considerable trade in corn and cattle. Its harbor has been much improved within a few years, and vessels of 250 tons can discharge at the quay. Steamers ply constantly between Drogheda and Liverpool, and a railway connects the town with Dublin. The registered shipping of the port in 1856 was 54 vessels of 6,018 tons; the entrances were 804 vessels, tonnage 107,123; clearances 634, tonnage 110,331.

DROITWICH (anc. *Salinæ*), a parliamentary and municipal borough of Worcestershire, England, 132½ m. by rail N. W. of London, pleasantly situated in the vale of the Salwarpe; pop. of the parliamentary borough in 1851, 7,096. It is celebrated for its salt works, which have been in operation for 1,000 years, and yield 50,000 or 60,000 tons of salt a year. The product of these works is shipped mostly to Gloucester by a canal upward of 6 m. in length, connecting with the river Severn. The brine contains 33 per cent. of salt, and is obtained from wells sunk within the town. Baths are established here for gouty and rheumatic invalids. It returns one member to the house of commons.

DROME, a department in the S. E. of France, formed of parts of Dauphiné and Provence, traversed by a navigable river of the same name, by the Isère, and by other affluents of the Rhone, and situated on the left shore of the latter river; area, 2,519 sq. m.; pop. in 1856, 324,760, comprising more Protestants than any other French department. Toward the E. are many picturesque and high mountains, the most celebrated of which are the *Montagne inaccessible* and the Montaiguille. The department produces famous wines, especially red Hermitage, which is made near the little town of Tain on the Rhone, and is also celebrated for its melons and truffles. Orange, olive, and chestnut trees abound here, and above all the mulberry tree, and the production of silk is consequently the principal industry of the department. With the exception of the fertile and beautiful valley of the Rhone, the soil is not favorable to agriculture, but mineral wealth, including iron, copper, and lead, is not inconsiderable; the mountains and forests abound with game, and apart from the important trade in wine, fruits, and silks, there are various manufactories of porcelain, bricks, beet root sugar, &c. This department comprises 4 arrondissements, 25 cantons, and 362 communes, and forms part of the 3d military division established in 1858, of which Lyons is the headquarters. Capital, Valence.

DROMEDARY. See Camel.

DRONTHEIM, or Trondhjem (Lat. *Nidrosia*), an E. province of Norway; area, about 18,000 sq. m.; pop. in 1855, 227,343. It comprises the districts of N. and S. Drontheim and part of Romsdal. N. Drontheim lies between Nordland, the Drontheim fiord, the mountains which divide it from Sweden, and the Atlantic; area, 8,832 sq. m.; pop. in 1855, 73,571. It is watered by the river Namsen. Chief town, Levanger. S. Drontheim occupies the S. shore of Drontheim fiord, and is bounded S. by the bishopric of Aggershuus or Christiania, and W. by Romsdal; area, 7,210 sq. m.; pop. in 1855, 96,304. Its largest rivers are the Nid-Elv, Guul-Elv, and Oerkel-Elv, and the chief town and capital of the whole province is Drontheim. Romsdal, part of which is included in the province of Bergen, occupies the S. W. part of the territory. The whole of Drontheim proper is mountainous, and much of it is well wooded. The coasts are indented by numerous bays, the most important of which is the Drontheim fiord, running 60 m. inland in an E. and N. E. direction, but describing with its windings a curve of 90 m., and the surface is dotted over with lakes. The inhabitants are engaged chiefly in the fisheries, cattle raising, iron mining, and to some extent in agriculture, but little grain is raised. Fruit, hops, flax, and hemp are the principal crops.—Drontheim, the capital of the province, and the third of the cities of Norway in importance and population, is situated in lat. 63° 25′ N., and long. 10° 23′ E., on a small gulf near the outlet of the river Nid, by which river and the sea it is almost entirely surrounded; pop. in 1855, 16,012. The most interesting edifice is the cathedral of St. Oluf, founded in the 11th century; and though dilapidated, the little of it that remains and forms part of the present cathedral is sufficient to show that it was originally a magnificent Gothic structure. The harbor of Drontheim is not deep, and is frequented only by small vessels. Its trade consists chiefly in exports of masts for vessels, of copper and iron, goat skins, and dried and salted fish. It has a public library, a collection of medals, a museum, and a Norwegian society of the arts and sciences, founded in 1760. The refined society and beautiful women of this city are much celebrated. Upon a rock in the midst of the harbor is the fortress of Munkholm, at first an ancient abbey, then a state prison, and now the chief fortification of the city on the sea side. On the land side Drontheim is commanded by a succession of picturesque heights. It was founded in 997, and for a long time was the residence of the kings of Norway, who in the 12th century were consecrated and crowned in its cathedral. As it was formerly built only of wood, it has suffered from repeated conflagrations, and been several times almost entirely reduced to ashes. The last conflagration took place in 1857.

DROPSY, a collection of serous fluid occurring in one or more of the closed cavities of the

body or in the cellular tissue, independent of inflammation. Inflammations of serous membranes, pleurisy, pericarditis, peritonitis, &c., are often attended with copious effusion; but the effusion here depends immediately upon the inflammation, and consists of the liquor sanguinis, not of serum alone. Dropsy is a symptom and not a disease, and is caused either by pressure exerted upon some part or the whole of the venous system, or by an altered state of the blood. In the vast majority of cases dropsy depends upon disease of the liver, the heart, or the kidneys. From the peculiarity of the hepatic circulation (see LIVER), when cirrhosis of the liver exists, the venous system of all the abdominal viscera becomes congested, and that congestion finally relieves itself by an effusion of serum into the sac of the peritoneum. In this way the swelling in ascites, dependent upon cirrhosis, begins in the abdomen, and the legs only become swollen secondarily. A scirrhus or other tumor by which the vena portæ is compressed produces dropsy exactly in the same manner as cirrhosis. When there is disease of the heart, that organ has more or less difficulty in emptying itself of the blood which is thrown into it; the difficulty commonly commences at the left side of the heart, and congestion of the lungs is a consequence; finally the right side becomes affected, there is congestion of the general venous system, and swelling takes place in the more dependent parts of the body; the great cavities, the abdomen and the chest, are afterward involved, and the dropsy becomes general. In Bright's disease the cause of the dropsy is probably to be sought in the deteriorated character of the blood (see ALBUMINURIA); in many cases disease of the heart is added to the affection of the kidneys, and increases the tendency to dropsy. Chlorosis, severe hemorrhages, any cachexia by which the character of the blood is greatly altered, are apt to be attended with more or less serous effusion into the cellular tissue. The treatment of dropsies is spoken of under the diseases of which they form a symptom.

DROSOMETER (Gr. δρόσος, dew, and μέτρον, measure), any instrument for measuring the quantity of dew that falls upon a definite area during the night. Dr. Wells, in his experiments upon dew, employed dry wool for this purpose, its increase of weight giving the quantity. Weidler made use of the bent lever balance, the pan being a plate of glass upon which the moisture condensed, and by its weight raised proportionally the counterpoise. The rain gauge may easily be made to serve the same purpose, the moisture being collected in the tube.

DROSTE, ANNETTE ELISABETH, Baroness Hülshoff, a German lyrical poetess, born Jan. 12, 1798, near Münster, died May 24, 1848, in a villa near the lake of Constance. Her whole life was consecrated to religion, study, and poetry. The feebleness of her health prevented her from mixing much with society, and, with the exception of a short stay at Bonn and Cologne in 1825, she passed most of her time in retirement in the country. Her poems were published at Stuttgart in 1844. She left many compositions, of which *Das geistliche Jahr nebst einem Anhang religiöser Gedichte* appeared in 1852. Medwin has translated some of her poetry into English.

DROUET, JEAN BAPTISTE, a member of the French convention, and the captor of Louis XVI., born in Sainte-Menehould, department of Marne, Jan. 8, 1763, died in Mâcon, April 11, 1824. After having served for 7 years as a common soldier, he returned to his native town, where he assisted his father, who was at the head of the post office. In the evening of June 21, 1791, the members of the royal family, on their flight to the frontier, stopped at the town for the purpose of changing horses, when Jean Baptiste identified the lady who travelled under the name of Baroness de Korff as Marie Antoinette, and the gentleman who accompanied her as Louis XVI., and caused them to be arrested. For this the national assembly voted him a reward of $6,000, which he is believed to have refused, and in Sept. 1792, he was chosen member of the convention by his native department. Here he became one of the most violent of the terrorists. He voted for the immediate death of the king, and on July 20, 1793, he proposed a wholesale butchery of the English residents of France. On Sept. 5 following he called upon the convention to organize a revolutionary army. In the same month he was sent by the convention on a mission to the northern army, where he fell into the hands of the enemy, who consigned him to the fortress of Spielberg in Moravia. This added to his popularity, and after having recovered his liberty in Dec. 1795, he was on his return to Paris received with every demonstration of enthusiasm, and not only declared eligible as a member of the council of 500, but appointed secretary of that body. He joined Babeuf's conspiracy, and was imprisoned, but made his escape. After the advent of Napoleon he dropped his republican convictions, became a sub-prefect, and fought in 1814 against the allies. During the Hundred Days he represented his department in the chamber of deputies, but under the restoration he was expelled from France. He succeeded, however, in passing the remainder of his life at Mâcon under the fictitious name of Merger. He was only identified after his death.

DROUET D'ERLON, JEAN BAPTISTE, count, a French general, born in Rheims, July 29, 1765, died in Paris, Jan. 25, 1844. A private soldier in 1792, he had risen in 1803 to the rank of lieutenant-general, and fought bravely at the siege of Dantzic, at Jena, and at Friesland in 1807, on which occasion he was severely wounded. Napoleon conferred on him the title of count of Erlon and a pension of $5,000. Subsequently he took a part in the conflicts in the Tyrol and in Spain, and was raised to the peerage in 1815, but Napoleon found fault with him at Waterloo. After the fall of the empire he lived in Germany until 1825, when he was permitted to return to France. He was reinstated in his

position as peer in 1831, and officiated as governor-general of Algeria in 1834 and 1835.

DROUYN DE LHUYS, Édouard, a French diplomatist, born in Paris, Nov. 19, 1805. He made his début under Louis Philippe as secretary of legation at Madrid; became chargé d'affaires in Holland; in 1836 returned to Madrid; in 1840 he was placed at the head of the commercial bureau in the French ministry of foreign affairs; in 1842 he was elected member of the chamber of deputies, in which capacity he voted, in 1845, against the government on the Pritchard indemnity question. This hostile vote led to his immediate dismissal from office. He then became one of the most active opponents of Guizot and the government of Louis Philippe, and was a prominent orator at the memorable reform banquets. After the revolution of 1848 he was elected to the constituent assembly, and subsequently officiated as minister of foreign affairs, and as ambassador in England. After the *coup d'état* of Dec. 2 he adhered to Louis Napoleon, and under the empire was once more made minister of foreign affairs. He took the task of asking the European governments to recognize the new emperor. Afterward he took also a conspicuous part in the negotiations relating to the Crimean war. He attended on behalf of France the peace conference at Vienna, where he evinced a readiness to side with the Austrian view of the question, which led to the appointment, May 7, 1855, of Count Walewski as his successor. Since then he has taken no prominent part in public affairs.

DROWNING. The specific gravity of the human body is very little greater than that of water, for though the muscles and the bones are heavier (the one being 1.085, the other 2.01), the fat (0.92) is specifically lighter, and the air within the thorax tends to restore the equilibrium. Owing to this, a very slight exertion enables a person to keep himself at the surface of the water; but any part of the person, an arm, &c., raised out of the fluid, acts like a weight imposed upon the rest of the body, and thus inexperienced persons are drowned by their own struggles. Death takes place by asphyxia; the blood in the lungs being unchanged by the action of air, the circulation through these organs is obstructed, and the blood becomes charged with carbon; insensibility is rapidly induced, and death takes place, frequently preceded by convulsive movements. The period during which the submersion may continue without death taking place varies in different persons. Dr. Lefèvre of Rochefort states that there was none among the Navarino sponge divers who could remain under water for 2 consecutive minutes; while according to Mr. Marshall, the best pearl divers of Ceylon rarely were submerged more than 50 seconds. But, according to some authorities, the divers of Ceylon have been known to remain 6 minutes under water; and Franchère, in his "Narrative of a Voyage to the N. W. Coast of America," states that he saw two Sandwich islanders dive in 14 fathoms of water, and that by his watch and those of his companions the time they remained under water was 4 minutes. In some instances bodies submerged but a minute, in despite of all attempts at restoration, have been found completely lifeless, while there are many cases on record in which recovery has taken place after a submersion of 5 minutes. In the "London Medical Gazette," vol. xxxi., a case is given of recovery after 14 minutes' submersion; the time here was calculated, but the circumstances render the calculation exceedingly probable. Cases of recovery are related after submersion for ½ or ¾ of an hour, but they are not sufficiently well authenticated. The explanation of recovery after prolonged submersion has been sought in the occurrence of fainting at the moment of the fall, and it is certain that during syncope the demand for air is very much diminished.—When the body is recovered a few hours after drowning, the skin is cold and pale, presenting sometimes patches of livid discoloration; the expression is placid, the eyes half open, the pupils dilated, the tongue swollen and pressed forward, and the lips and nostrils covered by a mucous froth; the fingers are sometimes found torn and abraded, and the hand grasping gravel or other substances which have been seized in a convulsive struggle at the bottom of the water. Internally the body presents few appearances which are characteristic of the mode of death; of these the presence of a mucous froth sometimes stained with blood, and perhaps of a little water in the trachea, and of water in the stomach, appear to be most noteworthy. The water contained in the stomach appears to be swallowed previous to death; after death the apposition of the sides of the œsophagus prevents the entrance of water into the stomach. When the body of a person is recovered after a short immersion in the water, means for resuscitation should immediately be had recourse to, and these should be perseveringly continued until recovery takes place, or the case is abandoned as hopeless. In a case related by Mr. Bloomfield 1½ hours elapsed before there was any appearance of returning animation; and in one by Dr. Douglas ("Medical Gazette," vol. xxxi., p. 449), success was met with only after 8½ hours. The plan proposed by the late Dr. Marshall Hall in 1855 is based on physiological principles, and has been found eminently successful in practice. For an account of it see Asphyxia.

DROYSEN, Johann Gustav, a German historian, born in Treptow, Pomerania, July 6, 1808. He was educated at Stettin and at Berlin, and between 1829 and 1840 discharged the duties of teacher at the Gray cloisters in the latter city, and of private tutor and professor at the university. In 1840 he went to Kiel as professor of history, and during a residence of 10 years was an active partisan of the duchies in the controversy between Holstein and Denmark. He was the author of the "Kiel address" of 1844, and in 1846 took part in the preparation of the protest signed by 9 professors of the university of Kiel. He also drew up a plan for the

government of Denmark and Schleswig-Holstein, which the outbreak of hostilities in the latter in 1848 prevented from being tested. Upon the establishment of the provisional government in Kiel he was sent as a plenipotentiary to the diet at Frankfort, where he proved himself an able advocate of the rights of the duchies. Subsequently he acted as a member of the Frankfort parliament. In 1851 he was called to Jena as professor of history, where he has since resided. Among his earlier works are translations of Æschylus and Aristophanes, a history of Alexander the Great, and a history of Hellenism. Subsequently he turned his attention to modern history, and has published "Lectures on the War of Liberation" (Kiel, 1846); "Life of Field Marshal Count York of Wartenburg" (Berlin, 1851); "History of Prussian Politics" (Berlin, 1855), his most important work.

DROZ, François Xavier Joseph, a French author, born in Besançon, Oct. 31, 1773, died Nov. 4, 1850. In 1803 he removed to Paris, where he became acquainted with the prominent philosophers of the day. After having previously published a variety of smaller works, which failed to attract attention, he succeeded in 1806 in making an impression upon the public mind by his *Essai sur l'art d'être heureux* ("Essay on Happiness"), which passed through numerous editions, and was translated by the Rev. T. Flint into English. In 1812 his *Éloge de Montaigne* made its appearance, followed in 1815 by his *Essai sur le beau dans les arts*, and in 1823 by his work *De la philosophie morale, ou des différents systèmes sur la science de la vie*, which was crowned with the Monthyon prize, and paved the way to his admission to the French academy. On occasion of his contest for election to this learned body, Lamartine was his competitor. In 1825 he wrote a book on the application of morals to philosophy and politics. He is also the author of an essay on political economy, and of a work on Christianity, which derives additional interest from the personal religious experiences added to the book under the title of *Aveux d'un philosophe Chrétien*, in which the author abandons his early theology and returns to the doctrines of the church of Rome. His most important literary achievement, however, is his *Histoire du règne de Louis XVI.* (3 vols., Paris, 1838–'42), with an introduction on the history of France from the time of Louis XIV.

DROZ, Henri Louis Jacquet, a Swiss mechanician, born Oct. 13, 1752, died in Naples, Nov. 18, 1791. In 1774 he removed to Paris, and became celebrated by his works, especially by his automaton representing a young lady playing on the harpsichord, following the music with her eyes and the movements of her hands, and, when done playing, rising and bowing to the audience. The most famous specimen of his inventive genius in this respect was a pair of artificial hands, which he devised for young La Reynière, who had lost his hands during a hunting expedition.—Pierre Jacquet, father of the preceding, born in La Chaux-de-Fond, July 28, 1721, died in Biel, in the canton of Bern, Nov. 28, 1790. In the divinity school of Basel he prepared himself for the church, but on his return home his attention became directed to the manufacture of watches and clocks, for which his native town is celebrated. While watching one of his sisters who was engaged in this employment, his own ambition was kindled, and he eventually succeeded in perfecting the different parts of clock work, and in supplying common timepieces with a musical machinery resembling the chime of bells and the sounds of the flute. He made many experiments for the purpose of effecting perpetual motion, and his most ingenious contrivance was a pendulum composed of 2 metals of unequal dilatability to counteract the effects of heat and cold. This was purchased by Philip V. of Spain, who bestowed a pension upon the artist. His most celebrated production was a writing automaton, which, by means of machinery within the figure, moved its fingers and hands, and formed letters. At the time of his death he was engaged upon the fabrication of a new astronomical clock.

DRUEY, Charles, a Swiss statesman, born in Feroug, in the canton of Vaud, in 1799, died March 21, 1855. Having studied law, he distinguished himself as an active member of the liberal party in his native canton, advocating several reforms in its church and school system, and after a triumph of his party in 1839 he became member of the state council. In 1841 he was elected first delegate from Vaud to the Swiss diet. Disagreeing with the majority of the great council upon a question relative to the monasteries of Aargau, he soon after retired from the administration, and became the leader of the opposition. A widely ramified political society, the *association patriotique*, extended his influence and popularity. When the expulsion of the Jesuits from the territory of the confederation was proposed by the canton of Aargau, he first declared against the measure, but finally for it, as agreeing with the opinion of the majority of the Swiss people. The great council of Vaud, however, gave unsatisfactory instructions to its delegation in the diet, in consequence of which the administration and constitution of the canton were overthrown by a popular movement in 1845. A provisional government was established, and a constituent council convoked. Of the former Druey became president, and afterward officiated in the same capacity in the state council. He was active in promoting the adoption of the new democratic constitution, and subsequently, as first delegate to the diet, was zealous in advocating the expulsion of the Jesuits, and the dissolution of the *Sonderbund* or separate union, formed by the Catholic minority of the cantons to defend their sovereign rights. He also promoted the energetic execution of those measures, and the foundation of the new federal constitution of 1848. Under this he was repeatedly elected a member of the federal council, and in

1850 he presided over that body as chief magistrate of the republic.

DRUIDS, a name given to the order of priests which in ancient times existed among certain branches of the Celtic race. As a term it has been variously deduced from the Saxon *dry*, a magician; from the German *druthin*, a master, or lord; from the Greek δρυς, and the Celtic *deru*, an oak; from the Hebrew *derussim*, or *drussim*, contemplators; from the Irish *drui* or *draui*, a sacred person, and from numerous other etymons; but the most probable derivation of it seems to be that given by the abbé Pierre de Chiniac, a French writer on the nature and dogmas of the Gallic religion, who refers it to the old Celtic compound *derouyd*, from *De*, God, and *rouyd*, speaking, a participle of the verb *rôuyddim*, to speak. It would therefore seem to mean those who speak for or of God, *i. e.* either the prophets or the theologians. Nor is the origin of druidism as an institution any more clear than the etymology of the name. As the druids did not allow their tenets and history to be committed to writing, and as the ancient Greek and Roman authors who describe them do so in the vaguest language, our knowledge of their peculiarities is necessarily limited. Pictet, in his work *Du culte des Cabires chez les anciens Irlandais* (Geneva, 1824), traces very decided affinities between druidism and the worship of the Cabiri in Samothrace. Pelloutier, in his *Histoire des Celtes*, on the other hand, argues that the druidical and Persian religions were identical. Maurice, in a dissertation on the origin of the druids ("Indian Antiquities," vol. vi., part 1), argues that they were the immediate offshoots and descendants of a tribe of Brahmins. Henri Martin, again, in his *Histoire de France*, discovers the Hindoo Sivaism in their reputed doctrines; while the Rev. W. L. Bowles, in the *Hermes Britannica*, derives them from the Egyptians; and Jean Reynaud, in a learned sketch in the *Encyclopédie nouvelle*, is inclined to refer them to the Zoroastrian Magi. It seems to be generally conceded that they were of eastern origin, because of the many and striking analogies between what we are told of their belief and practices, and what we know to be characteristic of the oriental nations. At the time when this mysterious order became known more clearly to history, *i. e.* in the first century before and after Christ, the druids inhabited chiefly Gaul and the islands of Britain. In Gaul their principal seats were in the west and centre, or in the modern Brittany, and along the Loire, while beyond the channel they were found in Wales and Ireland, and afterward in the island of Mona or Anglesea. According to some writers Brittany was their cradle; but the Welsh traditions relate that they entered Gaul from the remote east at the same time with that branch of the Celtic race which is denominated the Kymric or Cymraeg. At least it is evident that they did not prevail among the Belgic branches of the people of Gaul at the north, nor yet among the Aquitanian or Basque branches at the south. Their capital in Gaul was in the territory of a tribe called the Carnutes, corresponding pretty nearly to the province of Orléanais. Julius Cæsar is the ancient writer who has given the clearest account of the druids, and Mr. Godfrey Higgins, in his "Celtic Druids," the modern who has the most elaborately investigated their faith; but the Welsh triads are regarded by many as the most authentic sources of information in regard to them. Their characteristics, in the view of Mr. Higgins, consisted in the adoration of one Supreme Being, in the belief of the immortality of the soul and a future state of rewards and punishments, taking the form of a species of metempsychosis, in the use of circular temples open at the top, in the worship of fire as the emblem of the sun, in the celebration of the great Tauric festival (when the sun entered Taurus), and in the knowledge of an alphabet of 17 letters, though their instructions were always oral. If they acknowledged but one supreme God, they admitted other inferior deities, such as Hesus, Tarann, Belen, &c., to whom they paid a qualified worship. In their sacrifices to these their rites were sanguinary, and the bodies of human victims often smoked on the same altars with the carcasses of beasts. Their objects, however, were apparently moral, for they professed "to reform morals, to secure peace, and to encourage goodness;" yet with these high aims they connected pernicious superstitions and pretences to a magical knowledge. They assumed, says Cæsar, to discourse of the hidden nature of things, of the extent of the universe and of the earth, of the forms and movements of the stars, of the virtues of plants, and of the essence, power, and mode of action of the gods. On all these subjects their instructions were conveyed orally, and by means of verses, which required in the learner of them a novitiate of 20 years before they could be well committed to memory. The triads of the Welsh bards are supposed to be specimens of this species of verse. How well or ill founded their pretensions were it is now impossible to decide. Some knowledge of the movements of the heavenly bodies, beyond what simply pertained to the regulation of their religious festivals, they unquestionably possessed, inasmuch as they composed the year by lunations, which supposes an acquaintance also with the solar year. Various relics found in Ireland among the druidical remains, thought to be astronomical instruments designed to show the phases of the moon, are described by Sir William Betham in the "Transactions of the Royal Irish Academy." At the same time there was not a little of astrology, divination, and magic mixed up with their purer science. In their doctrine of medicine particularly, there was far more of superstition than of knowledge. To a great many plants they attributed a mystic sacred character; and most of all to the mistletoe, whose sanitary virtues, both physical and moral, were such, that they esteemed it an antidote to all poisons, and a cure for all diseases. It was gathered at certain sea-

sons, with the most formal and pompous ceremonies. As soon as it was discovered, twining the no less sacred oak, the druids collected in crowds about the tree, a banquet and a sacrifice were prepared, a priest in white vestments cut the twig with a golden sickle, two other white-robed priests caught it in a white cloak, two milk-white heifers were instantly offered up, and the rest of the day was spent in rejoicing. Perhaps they saw in the perpetual verdure of this plant an emblem of eternal life, or in its appearance during the winter, when all the rest of nature was sterile and dead, the independent life of Deity. Under similar mystic faith, doubtless, they plucked the *samolus*, or marsh wort, with the left hand, fasting, and without looking at it; and the *helago*, or hedge hyssop, after ablutions, or offerings of bread and wine, barefooted, and without a knife. The vervain likewise demanded distinct ceremonials. All these plants were regarded as powerful prophylactics and remedies, not only in respect to physical diseases, but to the dark workings of evil. They were carried about as charms, as well as amber beads, which the druids manufactured for warriors in battle, and which are still found in their tombs. A still more potent talisman was the serpent's egg, which, according to Pliny, oozed out of the mouths of serpents, when knotted together, and which they supported in the air by their hissings. That was the moment to seize it; and he who attempted to do so must suddenly dart from his hiding place, catch it in a napkin, and mounting a horse gallop off at full speed, to escape the pursuing serpents, until he had put a river between him and them. Among the druids, as among the Romans, auguries of the future were made from the flight of birds, and from an inspection of the entrails of sacrificed animals. Their profounder ceremonies, those which they celebrated in the depths of the oak forests or of secluded caves, are known to us only through the vaguest traditions, and in the stupendous but dilapidated stone monuments which strew the surface of France and Britain.—The druids were organized into a regular hierarchy, consisting of a triad, like almost every thing else among them, viz.: the bards, the vates or prophets, and the proper priests. The bards were poets not only of a religious but of a martial and satirical class. (See Bards.) The vates were the diviners or revealers of the future, who were charged with the conduct of sacrifices and other external ceremonies, and who, mingling in almost every event and relation of common life, stood as mediators or interpreters between the people and the more mysterious hierophants. These were the druids proper, or the priests, who dwelt in the depths of the oak forests, preserving the more interior and mystic doctrines of the faith, and consulting more directly the secret will of the divinity. They were also the teachers of the youth, who resorted to them in great numbers; and they retained to themselves also that highest means of power, the judicial function, which they exercised in cases of controversy and litigation. There was no appeal from their decision; all men, whether in a public or private capacity, had to submit to it, for the recalcitrant was condemned to excommunication, which cut him off from all sympathy and rendered him an outcast and an outlaw. Over the community or college of druids an arch-druid presided, whose authority was supreme and irrevocable, although his office was an elective one. The election was made by the suffrages of the whole body, but sometimes, in the rivalry of factions, led to serious conflicts of arms. At a fixed period every year they assembled at a consecrated spot in the territory of the Carnutes, which passed for the centre of Gaul, whither all resorted who had disputes to settle or decrees to solicit. It will be needless to add, that under such an organization the entire priesthood were exempted from all taxation or imposts, and from every burden of war or peace.—Affiliated to these 3 orders, without sharing their prerogatives, were prophetesses, or sorceresses, apparently divided into 3 orders also, according to their degrees of sanctity. Their rules were whimsical and contradictory, but their influence over the fears of the people was powerful. One branch of them could declare the secrets of futurity only to those who had polluted them; another was devoted to perpetual virginity; a third to long periods of celibacy, or they were allowed to visit their husbands but once a year; while others again had to assist at nocturnal rites, with their naked bodies painted black, their hair dishevelled, and abandoning themselves to transports of fury. Endowed with an imputed supernatural power, the Gallic mariner often went to consult them amid the reefs of the Armorican coast. "At night," says a historian, "when the tempests raged, as he skirted the savage promontory, he fancied that he heard strange cries and chants and wild melodies mingling with the wails of the wind and the eternal moan of the waves. On the summit of the misty crags he saw red phantoms gliding, with streaming hair and burning torches whose flashes were like lightning." These were the druidesses, weaving their mystic charms, healing maladies, conjuring up all living forms, raising or appeasing the elements, or extorting the secrets of fate. Their favorite resort was the island of Sena, where the 9 Senes dwelt, and the nameless islet opposite the mouth of the Loire, where once every year, between sunrise and sunset, they pulled down and rebuilt the roof of their temple; but if any one by chance let fall a particle of the sacred materials, she was torn to pieces, amid frantic dances, in which the Greeks saw the rites of their own Bacchantes, or the orgies of Samothrace. Being priests, philosophers, physicians, teachers, soothsayers, and judges, in whom were concentrated all knowledge and all power, who held relations with the elements and were the confidants of the gods, it is easy to conceive how the druids should attain to an almost absolute rule. That this rule was in many respects bene-

ficial, that they possessed and taught a higher civilization than that which had before prevailed, and that for a time they presented the only bond of unity which was possible in the barbarous and warring life of the Gauls, may be admitted; but it was also in the nature of their office, and among the inevitable results of the power they assumed, that it should degenerate into tyranny. They sooner or later, therefore, aroused the jealousy of another order in society, which Cæsar designates as that of the *equites* or warriors, or men of martial prowess, who had taken the lead in the political conduct and constitution of the tribes. It is supposed that these gradually overthrew the power of the druids in Gaul. Be that as it may, it is known that when that country was subdued by the Romans, the druidical religion gradually retired before the classic heathenism, and step by step withdrew, at first into Armorica, and then into Great Britain, where in the time of Nero it was assaulted and mostly suppressed. It lingered as a public worship longest in the island of Anglesea, whence it was finally driven out by the Roman troops amid a great deal of slaughter. Yet as a private superstition it continued to hold sway for many years thereafter over the minds of the Celtic tribes and their descendants. The only modern remains of druidism are those immense structures of stone, those *menhirs*, *cromlechs*, *dolmen*, and avenues, which, as we contemplate them in the immense ruins at Stonehenge, Avebury, and Carnac, still fill us with astonishment and awe. In fact, the soil of western and central France, as well as that of parts of Great Britain, is strewn with these gigantic memorials, whose original uses we cannot explain, but which the imagination inevitably connects with the dark and bloody rites of the druidical worship.

DRUM (Dan. *trom*, Ger. *trommel*), in music, a martial instrument of percussion, consisting of a hollow cylinder of thin wood or brass, covered at each end with vellum or parchment, the tension of which is regulated by small cords or braces on the outer side of the instrument acted upon by sliding knots of leather. The common drum is suspended at the side of the drummer, whence it is called the side drum, and is beaten upon at one end by sticks. An instrument similar in shape, but on a much larger scale, called the base drum, is beaten at both ends with drumsticks having leather pads on the knobs. Both kinds are highly effective in military bands, and seldom fail to excite soldiers under the fatigue of march or in battle. Another species of drum, called the kettle drum, consists of a thin copper basin, nearly hemispherical, the parchment covering of which is held by an iron rim, and tightened or relaxed by screws. Kettle drums are always in pairs, one instrument being tuned to the key note, and the other to the fifth of the key. They are generally supported on iron tripods. Instruments of percussion of the drum species have been familiar in the East from remote ages, and among savage races in all parts of the world are used in the celebration of religious rites as well as for the performance of music. They were common among the Egyptians, chiefly for military music, as early as 1600 B. C., some being long cylinders, similar to the tomtoms of India, which were beaten with the hand, while others were of a barrel shape and were beaten with sticks. Among the Greeks and Romans the drum, called the *tympanum*, had the form of the modern kettle drum or of the tamborine, and was beaten with a stick or with the hand. The drum was probably introduced into Europe by the Saracens and Moors, by whom it was called the *altambor*, whence the Spanish *tambor* and the French *tambour;* and in the first half of the 14th century it was generally adopted as an instrument of military music.

DRUMMOND, Henry, a member of the English parliament, noted for his wit and independence, born Dec. 5, 1786. He is the son of one of the foremost bankers of England, is a member of the royal academy of fine arts at Florence, and founder of a professorship of political economy at Oxford. He founded a church for the Irvingites, and has written much in favor of that denomination. He has also written extensively on various other theological, and on financial and political subjects, and published in 1859 a pamphlet against Mr. Bright's reform movement.

DRUMMOND, William, a Scottish poet, born at Hawthornden, co. of Edinburgh, Dec. 13, 1585, died Dec. 4, 1649. He spent about 12 years on the continent of Europe engaged in study and travel, but passed most of the remainder of his life on his family estate at Hawthornden, devoting himself to literature. He wrote a history of the five Jameses, comprising the history of Scotland from 1423 to 1542; but the work is of little value, and he is now chiefly remembered for his poetry and for his "Notes of Ben Jonson's Conversations with William Drummond of Hawthornden, Jan. 1619." As a poet he occupies an honorable position, and his versification sometimes bears a striking resemblance to that of some of Milton's poems. His sonnets, which form a considerable part of his works, are especially elegant.

DRUMMOND, Sir William, a British scholar, author, and diplomatist, born in Scotland about 1760, died in Rome, March 29, 1828. He first made his appearance as an author in 1794 ("A Review of the Government of Sparta and Athens," royal 8vo., London), was in the following year elected to parliament, sat also in the parliaments of 1796 and 1801, and was during the course of his life British ambassador at several foreign courts. In 1801, being then ambassador to Constantinople, he was made a knight of the crescent, an order instituted by Sultan Selim III. after the battle of the Nile. This gave him his title. He published a number of works, the most remarkable of which are: "Academical Questions" (4to., 1805), containing an attack on all kinds of dogmatism, embracing an exhibition of insoluble problems, and

tending to show the weakness of the human intellect; and "Origines, or Remarks on the Origin of several Empires, States, and Cities" (4 vols. 8vo., London, 1824–'29), his most considerable production. A work written by him, printed for private distribution merely, and entitled "The Œdipus Judaicus" (1811), brought upon its author much censure and criticism, in consequence of his attempting in it to explain away some of the narratives of the Old Testament as astronomical allegories. Drummond was an elegant scholar, and made an excellent translation of the satires of Persius.

DRUMMOND LIGHT. When quicklime is subjected to intense heat, such as is produced by the oxy-hydrogen blowpipe, the light emitted is exceedingly powerful and dazzling; the lime itself is slowly volatilized, and the surface around is covered with its sublimate. It was proposed by Capt. Drummond of the British royal engineers to employ this in the trigonometrical survey of Great Britain, whence it has been called the Drummond light. It has also been applied to the gas microscope, in which it gives the prismatic colors almost as bright as in the solar spectrum. A ball of lime only $\frac{2}{3}$ of an inch in diameter, as stated in the "Philosophical Transactions" for 1826, emitted a light equal in quantity to about 13 Argand lamps, or 120 wax candles; while in intensity or intrinsic brightness, it could not be less than 260 times that of an Argand lamp. Tried at Purfleet in a temporary lighthouse, it was found to cast distinct shadows upon a dark surface at Blackwall, 10 m. distant; and as the reflector was turned so that the light did not strike upon the spectator, an immense luminous cone was seen to sweep around with it, illuminating the horizon to a great distance. The wonderful intensity of this light would seem to render it by far the most suitable for lighthouses; but difficulties are encountered in its use which will probably continue to prevent this application of it. The deficiency of divergence in the rays emitted unfits it for a fixed light; and even if it could be applied to revolving lights, the difficulties attending the regular supply of the gases required render its constant maintenance (so essential for lighthouses) too precarious. M. Fresnel found that the light obtained by placing it in the focus of a great annular lens was exceedingly intense; but the divergence did not exceed 30′, so that in any revolving light of ordinary construction, the duration of the flashes would be too short to answer the purposes required.

DRUNKENNESS. When fermented or distilled liquors containing alcohol are taken in moderate doses, their first effect is to stimulate the heart and nervous system; the flushed cheek and quickened pulse show their influence on the one, while a rapid flow of ideas, a tendency to gayety, and a desire for muscular activity, arise from their action on the other. After these effects follow a sleep, somewhat prolonged, and a general derangement of the system, slighter or graver according to the idiosyncrasy of the patient. When larger quantities are taken, the phenomena of intoxication are produced; the nervous centres are more deeply implicated, and the effects upon the mind vary from the wildest excitement to the silliest drivel. The functions of the sensorium are deranged or perverted, thought is confused, vision and hearing are disturbed, articulation is thick and indistinct, and the voluntary muscles are no longer under the control of the will. Under such circumstances a sort of tetanic contraction of the muscles is often present, which curves the drunkard's body in a determinate direction, generally to one side. Sometimes all these phenomena are present; sometimes one or more of them are absent. One person can talk distinctly, and his reasoning powers are but slightly affected, but he reels as soon as he attempts to walk; another has the power of locomotion, but is betrayed by his thick speech and foolish look. From this condition, after prolonged sleep, one awakes with the digestive organs completely deranged, the strength prostrated, and the head aching. If the quantity taken be still greater, after temporary excitement, the patient passes into a state of coma. The countenance is generally pale, though sometimes flushed, the eyes suffused, the pupils dilated and insensible to light, the breathing slow and stertorous; the pulse, at first accelerated, becomes feeble, slow, and in bad cases extinct at the wrist; convulsions and strabismus sometimes occur. Such cases are always alarming, a fixed pupil and irregular breathing particularly so; when the latter symptom is marked, death is apt to follow. Death takes place from asphyxia, the venous system becoming gorged, the countenance pale or purple and swollen, and the surface cold. When a large quantity of spirits is swallowed rapidly, the patient sometimes falls almost immediately into a comatose condition, soon followed by death. From the above account it would appear that spirituous liquors first affect the cerebrum, as shown by the gay excitement and other manifestations of disordered intellect; next the sensory ganglia, as shown by the disturbance of sight, hearing, and voluntary motion; and finally the medulla oblongata and spinal marrow, causing at first imperfect and finally suspended respiration. When death is produced by the immediate effect of alcohol or distilled spirits, on *post mortem* examination, the whole venous system, the right side of the heart, the veins of the liver and lungs, and the sinuses of the brain, are found gorged with blood; the left side of the heart and the arteries are empty. Rarely, the stomach presents signs of inflammation as from the action of an irritant poison; more commonly, unless the subject was an habitual drunkard, its mucous membrane is unaltered. The brain is said to be firmer and whiter than ordinary, as if it had been for a short time immersed in alcohol. When a quantity of spirit so great as to threaten life has been swallowed, the use of the stomach pump, the administration of small doses of ammonia, and perhaps Marshall

Hall's "ready method" (see ASPHYXIA) in cases of asphyxia, are to be resorted to.

DRUSES, the popular name of a race and a religious sect of Syria, chiefly in the southern ranges of Lebanon and Anti-Libanus. Their name is derived from Darazi or Dursi, who, according to the Arabic historian Makrisi, appeared A. D. 1019, as a missionary of the Batenian sect, an offshoot from the Moslem stock, in Cairo. The Druses regard him as a heretical pupil of Hamsa, the Messiah of their system, and look upon the title which has been fastened upon them as a stigma, the only name which they acknowledge being that of Unitarians. The proper era of the Druses begins A. D. 1020, when Hamsa, a wandering fanatic, persuaded Hakem, the Fatimite caliph of Egypt, to declare himself a manifestation of God. The caliph was assassinated the next year, and Hamsa, retiring into Syria, continued to propagate the new faith among the mountain tribes. He and one of his followers, Moktana Boha-eddin, committed their doctrines to writing, and enjoined the strictest secrecy as to their nature. No member of another sect and no uninitiated Druse was to be permitted to see the sacred writings, and no revelation is to be made until the second advent of the lord Hakem and Hamsa his minister. A few copies of the sacred writings have, however, found their way to the libraries of Europe. The imperial library at Paris contains 5 volumes of them, the Vatican contains one, the imperial library at Vienna one, the library of the Leyden university 2, and the Bodleian library at Oxford 4. There are also several less important MSS. in the hands of private individuals; some are owned by the American missionaries in Syria. The first 3 volumes in the Paris library were brought from Syria in 1700 by the physician Nasr-Allah, and presented to the French king. The 4th volume was procured from the private library of M. Piques, who died in Paris in 1699. These volumes contain the exposition of the doctrines of the sect by Hamsa and Boha-eddin. They were translated into French by Petis de la Croix, in 1701. Their form is a small quarto. The 1st volume contains 14 pieces; the 2d, 26; the 3d, 15; the 4th, 13; the 5th, which is a fragment, contains 2 pieces. The Vienna, Vatican, and Leyden MSS., with 2 of the Bodleian, are duplicates of parts of the Paris MSS. Two of the Bodleian MSS. are supplementary, and contain matter not found in the writings of Hamsa. From a careful study of these sources, Sylvestre de Sacy (*Exposé de la religion des Druzes*, 2 vols., Paris, 1828) has been enabled to systematize the Druse theology. It is principally drawn from the Batenian and Ismaelite heresies, which arose within the Shiite division of Islam, in the 3d century of the Hegira, and were brought to Egypt by the invasion of the Fatimite caliphs. Traces of Gnosticism and of the Magian system of Persia are also found in the Druse writings. The characteristic dogma of the sect is the unity of God's being. His attributes are created and subordinate beings. He is incomprehensible, supreme, invisible, pure, the essence of true life. He can be known to his accepted children only through human manifestations. These have been numerous. The 10 Druse forms under which God has appeared are Ali, in India; Albar, in Persia; Alya, in Yemen; Moill and Kaim, in eastern Africa; Moess and Hadi, in Asia; Albou Zacharia, Mansour, and finally Hakem, in Egypt. The names are sometimes varied, but all the authorities hold that Hakem was the 10th and last earthly manifestation of God, and that no other is to be expected. He left the care of the faithful to 5 principal ministers, who are to direct them till the return of their divine lord. Of these the chief is Hamsa. His spiritual title is, the "Universal Intelligence." This Intelligence, the first born of Deity, was incarnated in the person of Hamsa, at the same time that Deity himself was incarnated in the person of Hakem. To him was committed the task of creation. He is what Christ is in the Arian theory. From him comes all wisdom, all truth. He is the medium by which the Lord communicates with the lower ministers, and through them with the human family. He dispenses power, and adjusts duties in the world; and he, in the last day, shall be the judge and the avenger. Hamsa, in this system, combines the functions of Jesus and Mohammed. The epithet which Boha-eddin applies to him is that of Messiah. Next to Hamsa is Ismail, the "Universal Soul." His origin was the rebellion of the "Rival," which made it necessary that the Intelligence should have in the world a supporter. His office is to inspire and sanctify souls, and prepare them to receive the heavenly doctrines. Next to Ismail is Mohammed, the "Word," born of the union of Intelligence with Soul. He has charge of Unitarian missions, and is enjoined to watch strictly the conduct and necessities of the brethren. He is the spiritual cadi, the chief bishop of the sect. The functions of the 4th minister, Selama, the "Preceding," seem to have been much the same with those of the 5th minister, Moktana Boha-eddin, the "Following;" for Selama is called the "right wing," Boha-eddin the "left wing." Both these ministers were called 3 years after Hakem's disappearance. They were probably intrusted with the charge of all knowledge and teaching except that of the Unitarian religion, which must come from the higher ministers. Boha-eddin had the special duty of organizing the Unitarian sect. He knew the retreat of Hamsa, consulted with him, and from time to time produced Hamsa's commands and directions. Below these 5 superior ministers are 3 styled the "Application," the "Opening," and the "Phantom." These ministers have each his earthly figure. They are the 3 feet of the candlestick which holds the candle of 5 elements. Beneath these there are 3 still lower classes, called Dars, Madhooms, and Mocassers, who form the connecting link between the earthly society and the heavenly orders, and hold their dignity only by virtue of their character and abilities. All of them are preachers, and have commission to destroy false

doctrine and to communicate the truth. The whole number of working ministers, expressed by the cabalistic word *sdk*, is 164.—The Druses hold that the most precious of substances were used for the composition of man's body, and that the world at the beginning had its perfect form. Men were made male and female, large and small, young and old, in myriads, in a fixed number, and no more souls have since been created. The race may change its figure and visible manifestations, but not its numbers. On the fall of man and the origin of evil, the Druse teaching is neither very clear nor very consistent. The minister of sin, the Rival, is as subtle and insinuating as the Hebrew Satan, but his work is not so well defined. This Rival stands between the Intelligence and the Soul, and his work of temptation is hindered by the counter work of both these celestial powers. The Druse reproduction of the story of paradise makes Enoch and Seth to be the rebellious pair whose sin entailed woe upon the race. The actual evils of sin are manifold—separation from God, confusion of knowledge, religious divisions, wars, jealousies, falsehoods. Sin broke the unity of the race, which the Druse religion aims to restore. The mediator is Hamsa. His mediation is not, however, vicarious, and the change which he works is not in the mind of God, but in the condition and spirit of men. He baffles Satan and remits sin, but does not strictly make an atonement. The Druse doctrine of free will and divine decrees is Pelagian. The length of every man's life, but not his individual acts, is foreordained. Transmigration of souls, which the Druses maintain, offers a convenient method of reconciling the theory of a fixed cosmogony with a righteous retribution. In passing from body to body, good men become continually better, bad men continually worse, though it is possible for them to change and become better. Ismail Temeami, the Soul, was formerly John the Baptist, and still earlier Elijah, while the soul of Hamsa was once in the body of Jesus. The Druse transmigration, however, is much more limited than the Indian or the Pythagorean; it denies that the souls of men are imprisoned in the bodies of the lower animals even for the sake of punishment. The souls of men, until the resurrection, keep the embodied form, except a few whose superior excellence permits them to exist as pure spirit. This resurrection will consummate the great spiritual plan. On that day the bodies of the faithful will be absorbed into God's own being, and transformed into spirit; all else will be destroyed. The saved will be few in comparison with the lost, but their condition will not be affected by any earthly memories. Until this day of resurrection a register of the acts of the Unitarians, good and bad, is kept by the Lord in a "safe place," where it will not "spoil nor decay." Punishment, in the mean time, consists in making the soul go downward to a lower society; reward, in elevating it to an ever higher sphere. The Druses not only reverence the holy names of Hebrew and Christian prophets, but they have a large calendar of their own canonized men. The life of man is divided into soul, body, and intelligence. Intelligence communicates to the soul the enlivening and divine spark. The work of the soul is to seek wisdom, and the substance of wisdom is to know God. Moral teaching is summed up in 7 commandments. The first is "truth in words," meaning in practice only truth to the religion and to the initiated; it is lawful to act and to speak falsehood to men of another creed, and in defence of the Unitarian faith. The 2d is "mutual help, watchfulness, and protection." The 3d is to renounce all other religions. The 4th is to be separate from infidels of every kind, not externally, but only in heart. The 5th, 6th, and 7th are semi-theological; the believer must "recognize God's eternal unity," must be "satisfied with God's acts," and "must be resigned to God's will." Under these 7 commandments numerous minor moral precepts are given, and special crimes are prohibited. Chastity, honesty, meekness, and mercy are Druse virtues; murder, theft, covetousness, cruelty, are sins. It is the deliberate opinion of intelligent writers, who have known and lived with them, that the average morality of the Druses is as high as that of any other eastern religious sect.—Of the character of the Druse worship there is but little precise information in their writings. That they have no prayer or preaching to which unbelievers can listen, has given rise to the report that they are without a religion. They observe no sabbath, they have no priestly class, their ceremonies are of initiation rather than ritual, and, except in their *holowes* and *ockals*, there is nothing to connect them with religious symbols. The *holowes*, or places of meeting, have little to distinguish them from common houses, except a somewhat larger room and more careful cleaning. They are bare of furniture, and show no sacred emblems. Every Thursday evening the brethren meet, opening their assembly freely to strangers, but allowing none to learn any more than they can see. The revenue of these holowes (for, like the convents of Europe, they have landed property) is dispensed in charity. The *ockals* (whose name is derived from the Arabic *akl*, intelligence) are the wise men of the Druse sect, who have taken all the degrees, and have charge of the highest religious interests of the community. They are chosen after long probation, in which severe self-denials, including abstinence from tobacco, are required. A year must pass before the first degree can be taken; and after initiation the strict rules of discipline continue to bind them. Any class and either sex may furnish candidates, and any one, however holy, is liable to fall from grace. The ockals have among the people only that position which the leaders have in the meetings of the society of Friends. They are not salaried, and work with their hands like the rest, but are universally respected. They take the lead in the

meetings, read the Koran or the Christian Scriptures if infidels of these sects are present, and their own religious books after infidels have gone. Some of them are ascetics, but asceticism is by no means required. Some of them will fight in time of war, though they are by profession bound to peace. They are the arbiters of disputes, and the saints of the people when they have passed from the earth. The proportion of ockals or initiated religionists to the whole number of the Druses is about one to four.—The form of government among the Druses is half feudal, half patriarchal. The sheiks, who are the strongest, most graceful, and most intelligent men of the various tribes, preserving very carefully the purity of blood, owning by hereditary tenure the best lands and the absolute service of their tenantry, rule by unwritten law, and are sustained by the traditional loyalty of their vassals. They are leaders in war and in sports, and direct almost despotically the economy and policy of the tribes. Some of them live in comparative state, but more often their fare and their habits are those of the common people, and they labor with the rest. Their commodious houses are rarely without guests. The sheiks of different tribes are often at strife together; but when the race is called to contend with other races they are united as one man, and obey implicitly the orders of their sovereign emir, with whom the general direction of the tribes by tacit consent resides. It is a league of mountain barons supporting a king elected without suffrage and governing without statute. The Druse country is chiefly a mountain region, and difficult to cultivate. Except in the level tract of Cœle-Syria, where a few of them dwell, the rains of winter are apt to destroy the labor of spring and summer. The patches of soil, too small and rough for the plough, must be turned up and watered by hand. Industry has overcome this natural disadvantage; and in no part of Syria does the face of the mountain show higher culture. The fig, olive, mulberry, and apricot, vineyards trained to grow in crevices of the rock, with small groves of evergreen, surround and embosom the villages which cling to the slopes, or fill the narrow valleys. Usually the village is placed near the entrance of a pass, so that in case of attack it can be more easily defended. From the level of the pathway the houses rise in terraces, till in some instances they reach the top of the mountain. The habits of the people are simple and primitive. Most of them till the soil; a few are artisans; the spinning and weaving are done by women in their houses, and the children of both sexes are kept at school. Every boy learns at an early age how to use the lance, the dagger, the sword, and the gun. The method of fighting is not in masses so much as by ambush and in small bands. Having no artillery, they are compelled to this style of war, and in it they have no superiors. If the war be one of defence, the soldiers ask for no pay; and when they go on expeditions of forage or plunder at the call of some other tribe, they are content with meagre bounty. Their code of martial honor is very precise; deceit between comrades is lasting shame, and cowardice is never forgotten. Success is a criterion of worth, and the chief who has been worsted in conflict is in danger of losing his place of honor. So frequent are the calls to warfare that the Druses would suffer if their habits were improvident like those of the surrounding Arabs; but the reserved fund, laid by in time of peace, and bequeathed from father to son, secures them against absolute want. Few are rich, but scarcely any are destitute. The relation of the sexes is far more honorable than among the Turks or Arabs. There is but one wife in the house, and her rights are admitted and protected; she can own personal property, retain the half of her dowry money after divorce, and is not compelled to marry against her inclination. An ockal regards his wife as in every particular his equal. The marriage customs of the people resemble those of the Arabs, with somewhat less of ceremony. There is no religious rite, but plenty of bridal presents. A birth, though an occasion of rejoicing if it be of a son, is attended by no special celebration. But the greatest parade is made at the burial of a sheik. All the neighboring sheiks with their retainers attend. All day long the ceremonies last, with howlings, frantic gestures, and doleful chants, followed by a solemn and impressive procession. At the tomb, sentences are repeated from the Koran, and the sheiks sit silent around while the will of the deceased is read. The burial of an ockal is marked by even more fervor of grief, especially if the sanctity of the man has been accompanied by narrow fortune. His dress is parted into fragments, which become sacred relics, and the tomb itself becomes a place of pilgrimage.—The number of Druses in the whole of Syria, from the plain east of Damascus to the western coast, is reckoned to be about 70,000. Some of these dwell in scattered families in the larger towns, and in the villages of the Maronites. In the towns at the foot of Mount Hermon, they make a considerable part of the population and have great influence. The Druses of the Anti-Libanus are a more warlike and restless class than their brethren beyond the Litany. But the proper home of the Druse people is in the Lebanon mountains, from the latitude of Beyroot to that of Tyre. The principal towns are Deir el Kamer, once the capital; Shwyfat, near Beyroot, where the emir Emeen, the present governor of the Druses, resides; Heittat and Allaye; Abeigh, where the American Protestants have a flourishing mission; Bakleen, Muctara, Bavook, and Ainshalti, where there is also a missionary station.—The history of the Druses is so interwoven with that of the surrounding tribes of the Maronites, and of Moslem and Christian strifes in Syria, that it is impossible to treat it separately. For 300 years, the emirs of the mountain, at the head of whom

was the family of Tnooh, were in perpetual conflict, now with the Franks as allies of the Damascus sultan, and now with the sultan himself for their own independence. Early in the 14th century they were the victims of Mohammedan persecution. The beginning of the 17th century was marked by bloody battles between the troops of the pasha at Damascus and the mountain tribes, and by still more bloody civil wars among the latter. In 1614 the emir Fakaradeen, the most famous and powerful of the Druse chieftains, resigned his authority to his son Ali, and visited Italy with a large retinue. He was received with distinction at the courts of Naples and Tuscany, and made a highly favorable impression by his ability and the dignity of his manners. A palace at Pisa was appropriated to his use, and he resided there 5 years, at the expiration of which he returned to Syria and was reinstated in his authority over his tribe. He extended his jurisdiction by conquest and policy until he became the virtual ruler of nearly the whole of Syria. He was finally subdued by the armies of the sultan, made prisoner and sent to Constantinople, where he was put to death, April 13, 1635. The districts of the mountain were finally parcelled to the various sheiks, as tributaries of the pasha. About 1771 these tribes made common cause against the Arab Metualis, whose rebellion against the Turks threatened to dislodge all the tributaries of the Ottoman power. Invaded by the Russians, the Egyptians, and more than all by the formidable Daher, pasha of Acre, they were driven from their homes, plundered and dispersed. Under the bloody pasha Jezzar, though the Druses suffered, yet on the whole their relative power was increased. The emir Bechir Shehaab, though a Christian by profession, belongs to the history of the Druses more than to that of the Christians in the Lebanon. His capital was in the heart of their mountains, and his policy was influenced by their dictation. Their most powerful sheik, Bechir Jumblatt, was his ally, adviser, and almost his rival. The alliance between these 2 powerful chiefs was broken about the close of 1824, when the extortions of the emir drove the Druses into revolt, and sent Jumblatt into voluntary exile. The sheiks of the various tribes rallied to avenge his cause, but were eventually defeated. Within the last 30 years the Druses have been repeatedly called to take up arms. They bore a part in the strife which resulted in the restoration of Syria to the Turkish sultan; in 1842 they were again in insurrection against the Turks; and more recently they have waged a harassing warfare against their rivals the Maronites. They live in continual readiness for battle; and their martial propensities are a source of constant apprehension to the other inhabitants of the mountain. In spite of their adoption of the religious customs of the Moslems, of their readiness to educate their children in Christian schools, of their use of the Arabic language, which they speak and write as purely as any tribe in Syria, and of their free intercourse with strangers, the Druses remain, even more than the Jews, a peculiar people. They are rarely converted; they marry within their own race; they adhere tenaciously to their traditions; and they baffle all efforts to discover their cherished secrets. They are stigmatized as infidels, robbers, and savages; yet they seek for knowledge, observe honor, and practise domestic and social virtues, in a way that compels the praise of intelligent Christian observers. In their religion there is no sign of idolatry; they are less fanatical than the sects around them, and they covet no proselytes. The bad name of that caliph whom they claim as their founder and worship as their god is fairly compensated by the pure lives of many whom they honor as saints, and by the heroism of their feudal leaders.—The fullest account of the Druses in the English language is contained in Col. Churchill's "Mount Lebanon" (3 vols. 8vo., London, 1853).

DRUSUS, Claudius Nero, commonly called Drusus Senior, to distinguish him from his nephew, Claudius, the son of Tiberius, born 38, died 9 B. C. His mother Livia Drusilla was divorced from her husband Claudius Tiberius Nero, and married to the emperor Augustus 3 months before the birth of the subject of this notice; and the latter, on the death of his father not long afterward, was committed to the guardianship of his stepfather. His noble bearing and the liberality of his political sentiments won him early popularity, which was increased by the exploits of his maturer years. His career was short and brilliant. His first military command was against the Rhætians, who were accused of having plundered subjects and allies of Rome, and whom he defeated as they were about to make a descent upon the plains of Italy. He afterward joined his brother Tiberius, and in conjunction with him thoroughly subdued this formidable tribe. In 13 B. C. he was appointed governor of Gaul, and in the following year defeated the Sicambrians, and afterward the Frisians. The rest of his life was mostly taken up with his campaigns against other German tribes, in the course of which he ravaged a great portion of their territory and penetrated as far as the Elbe. It was on his last expedition that he reached this river, and on his return he met his death, according to the commonly received account, from an injury received by the falling of his horse. Drusus was the first Roman general who penetrated to the German ocean. He dug a canal connecting the Rhine with the Yssel, and probably widened the outlet of the Zuyder Zee, so as to give a navigable passage from the Rhine to the ocean.

DRY ROT, a disease in timber to which public attention has been particularly directed only within the last 100 years. It commences within the body of the stick, however well this may be protected by paint or varnish, and, without any indication of its existence upon the outside, it goes on converting the fibre of the wood into

dry dust, and spreading from the internal parts outward. Common rot commences on the outside by the agency of atmospheric causes of change, and gradually works inward. Dry rot is most likely to affect timber in warm, close, and moist situations, where the wood becomes coated with a fine mould of a brownish white or dirty yellow color, which as it spreads ramifies into the forms of algæ or sea weeds, and becomes in the process of time by the filling in of its interstices dense and tough, like leather. This fungous growth has been seen to fill a hole bored into a sound oak timber of one of the old ships of the British navy, so that within 24 hours it had become so compact that it could be drawn out with a stick. It sometimes increases so rapidly that heavy sticks of oak timber are destroyed in a few months. In some of the mines of France, as stated in the *Annales des mines* (vol. vii., 1835), the timbers used for props seldom last longer than 15 months, and some are rendered unfit for use even in as many days. Locust substituted for the oak was found to be much more durable. There is thus a great difference in the liability of different kinds of wood to be attacked by this disease. Cedar, locust, teak, and live oak resist its attacks better than most other woods used in ship-building, and wood of close texture, as box, ebony, cypress, and mahogany, is rarely attacked by it. Pliny, who seems to have been acquainted with this cause of the decay of timber, observed that the more odoriferous a piece of timber is, the more durable. He also knew that the part of the timber most subject to rot was the sap wood, outside of the heart, and recommended the cutting of this away in squaring the stick. But kinds of wood, not the least liable to suffer from dry rot, have in favorable situations stood unharmed for several hundred years, apparently harder and more solid than when first hewn. Such situations are where the air can circulate freely around the timber, and it is protected from moisture; or where the air is entirely excluded, as in tight structures of masonry, or beneath the surface of the water, or where the wood is buried among antiseptic matters, as in a peat bog. Heart wood, being of close texture, without cells or sap, is not so readily attacked as is the sap wood. To some condition of the sap it is evident the decay is to be attributed; and it is now commonly understood to be owing to a vegetable growth which takes place within the pores of the wood, the sap having probably carried up the minute seeds of the fungus during the growth of the plant. This fungus is known to botanists by the name *merulius lachrymans*. The vegetation at first is scarcely perceptible; it appears in delicate white filaments, which spread toward the surface, interlacing with one another, and presenting the leather-like appearance as these fill up. The fibre of the wood is now attacked and corroded, and in a short time the ligneous mass becomes a loose cellular tissue, readily falling into powder. Frequently the surface remains sound, while the whole central part is thus decomposed; but occasionally this process commences at the surface. (M. Aubuisson, *Annales des mines*, vol. vii., 1835.) In the living tree this growth is not readily produced, but it seems to be nourished by the putrefactive fermentation of the juices of the plant, the commencement of which is dependent upon the presence of some acid. By arresting this fermentation the decay may be prevented, and various methods are successfully applied to effect this purpose. The dissipation of the fluids by evaporation produced by thorough seasoning, and then securing the wood from the entrance of moisture through its pores, is a common but imperfect method of protecting timber. If the seasoning is conducted under water the result is more completely attained, the juices appearing to be dissolved and entirely removed. Burying the wood for a time in the ground answers the same purpose. A third method consists in filling the pores of the wood with some substance which resists putrefaction, and is destructive to vegetable and animal life. None has been found to answer the purpose more effectually than corrosive sublimate. Its use was recommended by Sir Humphry Davy, and it was successfully applied by the late Mr. Kyan in the process called kyanizing, which consists in steeping the timber in a solution of this salt. Wood kept for a few hours in a boiling solution of copperas and then thoroughly dried is rendered exceedingly hard and durable. The sulphates of zinc and of copper also produce the same effect, and the chloride of zinc is highly recommended. A number of other salts may be substituted for these, avoiding those which are liable to deliquesce or attract moisture from the air, as this serves to keep the wood damp, and causes iron bolts and fastenings to corrode. Common salt is much used in ships, both of the mercantile and naval service. It has the objection of deliquescing, particularly if it contain much of the bitter salts, as the chloride of magnesium, and consequently the vessels are always damp, and liable for this reason to be unhealthy. The salt is packed between the timbers when the vessels are built, and is inserted into holes made in them for the purpose. It is always considered an important object for a new ship to get a cargo of salt on account of its permanent benefit to her timbers. Solutions of salts of pyroligneous acid have also been successfully used, the air being first exhausted from the wood by powerful air pumps, and the solution being then forced into the pores. Most of these processes are objectionable on account of the expense and trouble attending them; and as the second method above named has long been found sufficient, it continues to be commonly preferred. It is said to have been an ancient practice in England to steep the oak planks for threshing floors and those intended for the wainscoting of houses in running water. Recently it has been found that timber immersed for some time in salt water is made more durable; and even when

the dry rot has made considerable progress, the wood is preserved from further decay. Attention has been forcibly called to this fact by the results of the sinking of different ships belonging to the British navy, the timbers of which were affected by the rot. On being raised to the surface after an immersion of several months, the fungus had disappeared, and the wood afterward continued free from decay. It is probable that the durability of the planks used in the bends of vessels is owing to the steaming process to which they have been subjected, the juices which tend to produce fermentation being thus dissolved out as effectually as by steeping in water or burying in the earth. Seasoning in dry air, though it may cause the destructive juices to be hardened, and thus rendered harmless so long as they continue in this condition, is proved to be imperfect when the wood is exposed in damp situations. The moisture penetrating the pores redissolves these juices, and the fungus soon makes its appearance. Wood that has lasted perfectly well for 650 years has, by an exposure in unfavorable situations, been attacked in a few weeks by the dry rot.

DRYADS (Gr. δρυς, an oak, or large wild-growing tree), a class of nymphs in ancient Greek and Roman mythology. According to some they were the same as the hamadryads, and, being attached to particular trees, their life was limited by that of the tree in which they lived. Another account is that the dryads were the patrons of forests and trees in general, and were thus distinguished from the hamadryads, who inhabited each a particular tree.

DRYANDER, Jonas, a Swedish naturalist, born in 1748, died in London in Oct. 1810. He was educated at the university of Gottenburg, and took his degree of doctor in philosophy at Lund in 1776, on which occasion he published a dissertation in opposition to the theory of those naturalists who asserted that fungi might be the production of animals. He subsequently became the friend and pupil of Linnæus; and visiting England as the tutor of a young nobleman, he was introduced to Sir Joseph Banks, under whose roof he resided after 1782, in the capacity of librarian. He was also librarian of the royal and Linnæan societies, of the latter of which he was one of the founders, and at the time of his death vice-president. He wrote several papers on botanical subjects, and superintended the publication of the *Hortus Kewensis* and Roxburgh's "Plants of the Coast of Coromandel." He was one of the most accomplished of modern bibliographers, and his *Catalogus Bibliothecæ Historico-Naturalis Josephi Banks, Baroneti* (5 vols., London, 1798), is a model of admirable arrangement, and the most comprehensive catalogue of the kind ever published.

DRYDEN, John, an English poet, born in the parish of Aldwinckle All Saints, Northamptonshire, Aug. 9, 1631, died May 1, 1700. He belonged to a respectable Puritan family. His father was a magistrate under Cromwell. John, the eldest of 14 children, received a good education at Tichmarsh and at Westminster school. At the latter he showed his poetical gifts in a translation of the 3d satire of Persius and an elegy on the accomplished young Lord Hastings. He was graduated at Trinity college, Cambridge, in 1654, went home on the death of his father in the same year, and soon after returned to the university, where he remained until 1657. His relative, Sir Gilbert Pickering, a member of Cromwell's council, induced him to come to London, and gave him a petty clerkship. He celebrated the death of the protector in his "Heroic Stanzas;" but his connection with the Puritan party was the result of circumstances rather than sympathy. The restoration called forth his *Astræa Redux* in 1660, and the coronation of Charles II. another poem of panegyric soon after. At this period of his life he seems to have eked out the pittance which he received from his paternal estate by writing prefaces and other occasional pieces for the booksellers. The patronage of Sir Robert Howard bettered his fortunes, and he soon became known as a ready versifier and a stanch royalist. About the same time he began to write for the stage. His first play, the "Wild Gallant," produced in 1662, was not successful. It was followed by the "Rival Ladies" and the "Indian Emperor;" but scarcely had he gained the public ear when the plague and the great fire of London put a stop for a time to all theatrical representations, and drove him to a less profitable employment. He busied himself in composing his "Essay of Dramatic Poesy," in which he defends the use of rhyme in tragedy. In 1663 he was married to Elizabeth, daughter of the earl of Berkshire, and sister of Sir Robert Howard, a lady who added little to his fortune, and still less to his happiness. It was from the earl's seat in Wiltshire that he dated his *Annus Mirabilis*—the year of wonders (1666), in which he celebrates the great fire, the duke of York's victory over the Dutch, and other prominent events. His devotion to the court, no less than the merit of his verse, obtained for him in 1670 the post of poet laureate, vacant since the death of Davenant in 1668, with that of historiographer royal, the united salaries of which amounted to £200. On the revival of the drama he became an active and successful writer for the stage, and was soon engaged to furnish for the king's theatre 3 plays a year, for which he received 1¼ shares of the profits of the company. Though he did not fulfil this agreement, having produced only 18 plays in 16 years, the actors seem to have valued his services too highly not to take them on his own terms. But if he pleased the public, his exaggerated style did not escape the ridicule of the wits of the court. Villiers, duke of Buckingham, brought out in 1671 a comedy called the "Rehearsal," in which the poet laureate was satirized under the name of Bayes. Its brilliant wit won it an enthusiastic reception, and how deeply Dryden felt the blow may be judged from the revenge which he took 10 years afterward. Meanwhile he had to suffer

in another way. An "Essay on Satire," written by Lord Mulgrave, and attributed to Dryden, who seems indeed to have revised it, gained him the enmity of the earl of Rochester; and on Dec. 16, 1679, as he was returning at night from Will's coffee house to his home, he was set upon and cudgelled by 3 hired ruffians. In 1681 appeared his "Absalom and Achitophel," a satire on the plot for securing the succession of Charles's natural son the duke of Monmouth, in which, under the names of David, Absalom, and Achitophel, he represented the king, Monmouth, and Shaftesbury; while in Zimri, who

> —— in the course of one revolving moon
> Was chemist, fiddler, statesman, and buffoon,

he drew his old enemy, the author of the "Rehearsal," and fully repaid the smart he had felt under his satire. The success of the poem was unbounded; Dr. Johnson's father, an old bookseller, said he knew of no publication except Sacheverell's "Trial" which had ever reached so large a sale. A medal struck by the friends of Shaftesbury to commemorate the refusal of the grand jury to indict him for high treason, furnished the title and subject of a fresh political satire. "The Medal" soon appeared, and was answered by a score of rhymesters, one of whom, Elkanah Settle, by his "Medal Reversed," is said to have fairly divided with Dryden the praises of the town. "MacFlecknoe," published about 1682, was a biting satire on the poet Shadwell, and fell below Dryden's political writings in interest only because the subject was inferior. In 1682 were produced also the *Religio Laici*, a defence of the church of England, and the 2d part of "Absalom and Achitophel." Of this, however, the greater portion was written by Nahum Tate; Dryden contributed only 200 lines, but in these his rivals Shadwell and Settle were handed down to the ridicule of posterity under the names of Og and Doeg. A few classical translations, some miscellaneous poems, and 2 pieces for the stage, were his only compositions during the next 3 years, until he was called upon as poet laureate to mourn the death of Charles II., and celebrate the accession of James. Under the new monarch the religious doubts which seem to have troubled him several years before were solved by his submission to the Roman Catholic creed. The sincerity of his conversion, at a time when the change suited so well his worldly prospects, has been and must doubtless remain a moot point. He was sharply attacked by his contemporaries, and among the earliest of his pieces in defence of his faith appeared, in 1687, the "Hind and Panther," an allegory absurd in design, but forcible in execution, wherein the points of difference between the two religions are discussed in musical verse. The revolution of 1688 robbed him of his place, and reduced him once more to the necessity of writing for bread. From 1690 to 1694 he composed 4 plays, and during the next 3 years was busy with his translation of Virgil, for which he is said to have received £1,300. In 1698 he began his adaptations of Chaucer, contracting with a bookseller to furnish 10,000 lines for £300. This bargain produced his "Fables," consisting of many of the choice stories of Homer, Ovid, Boccaccio, and Chaucer, translated or modernized in flowing verse. The noble ode for St. Cecilia's day, often called "Alexander's Feast," formed part of this collection. It was the last of Dryden's great works, though he published some minor pieces afterward. He died of mortification of the leg, and was buried next to Chaucer in Westminster abbey, where Sheffield, duke of Buckingham, erected a monument over his remains in 1720. His wife and 3 sons survived him.—Dryden was reserved in his habits, but kind and benevolent. At Will's coffee house, the great resort of the wits of London, he was the oracle by common consent, and though his part in conversation was seldom brilliant, a pinch from Dryden's snuff box, says Sir Walter Scott, "was equal to taking a degree in the academy of wit." He was domestic in his tastes, an affectionate father, and, notwithstanding the bitter temper of his wife, a faithful husband. The licentious spirit of the time, which his dramas, so far from repressing, did every thing to encourage, found no reflex in his private conduct. His rhyming tragedies have little beside their diction and versification to recommend them; his comedies, with the exception of the "Spanish Friar," are beneath his fame; and though he wrote 27 plays, only one or two are now spoken of. Many of his dedications are disfigured by the most abject flattery, and his early poems are marked by the false taste, Gallicisms, and unnatural conceits which characterized the period of the restoration. It was only with the production of his first political satire that he developed his full powers and marked out a new path in which he had no rival. His bold sketches of character, wanting often in polish, but alive with individuality, have never been surpassed. From the death of Milton to his own death he was confessedly the first of the English poets; but we have too often cause for sorrow that the harmony of his verse, the happiness of his illustrations, and the brilliancy of his wit should be defiled by the coarseness of party rancor and the taint of a corrupt fancy. As a translator, Dryden's merits have been much discussed. He gave us the first good English version of the Æneid, but he could not reproduce the tenderness and quiet majesty of the Roman poet. In prose, he has left many specimens of strong, genuine English, mostly in the form of prefaces and dedications. Among the principal editions of his works are his dramas (6 vols. 12mo., London, 1718); miscellaneous works (4 vols. 8vo., London, 1760); prose works, edited by Malone (4 vols. 8vo., London, 1800); poems, edited by Warton (4 vols. 8vo., London, 1811), by Sanford (Philadelphia, 1819), and by Mitford (5 vols. 12mo., London, 1832; Boston, 1854); and a complete edition of all his writings, with notes and a memoir by Sir Walter Scott (18 vols. 8vo., Edinburgh, 1818). The

"Fables," ornamented with engravings after the designs of Lady Diana Beauclerc, were published in folio (London, 1797). The life of Dryden has also been written by Dr. Johnson, and forms the most eloquent and discriminating of all the "Lives of the Poets." A brilliant essay on his life and writings, by Macaulay, will be found in No. xciii. of the "Edinburgh Review."

DRYING OILS. A number of vegetable oils, as linseed, nut, poppy seed, and some others, exhibit a strong tendency to absorb oxygen from the air, and, when exposed in thin layers, to dry into a resinous kind of varnish. The addition of a small quantity of oxide of lead greatly accelerates the process. These oils are consequently well suited for mixing with coloring matters to form paint for wood work. They impart no color of their own, and serve to bind and secure the color to the wood, which they also aid to protect by their resinous coat. The so-called greasy oils have no such tendency to dry by exposure, but on the contrary become rancid.

DUANE, William, an American politician, and editor of the "Aurora" newspaper, born near Lake Champlain, N. Y., in 1760, died Nov. 24, 1835. At the age of 11 he was taken by his mother, then a widow and a Roman Catholic, to her native country, Ireland, and liberally educated; but his marriage at the age of 19 with a Presbyterian lady so offended his mother that she immediately dismissed him from home, and no reconciliation was ever effected. He learned the art of printing, and in 1784 went to seek his fortune in India. He rapidly amassed property, and became editor of an Indian journal, entitled the "World." Having taken sides against the local government in a dispute with some of its troops, he was seized and sent to England, and his large fortune was confiscated. Having in vain petitioned parliament and the East India company for redress, he began to devote himself to the periodical press of England, and became editor of the "General Advertiser," siding in politics with the party of Horne Tooke and others. In 1795 he returned to America, and became editor of the "Aurora," published at Philadelphia, which was made by his able management the most influential organ of the democratic party; so much so, that Jefferson attributed to its vigorous support his own election to the presidency. The change of the seat of government from Philadelphia to Washington caused the "Aurora" to decline in political importance. Duane retired from its editorship in 1822, and then travelled through the republics of South America, with whose struggles for independence he had long sympathized. On his return he published an account of these travels, and was appointed prothonotary of the supreme court of Pennsylvania for the eastern district, an office which he retained until his death. Mr. Duane served as an officer in the war of 1812, and published two works on military tactics, a "Military Dictionary" (Philadelphia, 1810), and a "Handbook for Riflemen" (1813), which were for some time standard authorities.

DUBAN, Félix Louis Jacques, a French architect, born in Paris, Oct. 14, 1798. He studied under Debret, and having gained the first prize for architecture at the school of the fine arts, was enabled to spend several years in Italy. His first work of importance was the completion of the *palais des beaux arts*, in the execution of which he is charged with having sacrificed harmony of proportion and strength to a fondness for ornamentation. In 1845 he was employed in the restoration of the ancient chateau of Blois, and in 1848 received from government the appointment of architect of the Louvre, with the general direction of the restoration of a part of the building. The façade on the river side, and the Apollo gallery, have been restored from his plans.

DUBLIN, a maritime county of Ireland, province of Leinster, bounded N. and N. W. by Meath co., S. W. by Kildare, S. by Wicklow, E. by the Irish sea; greatest length from N. to S. 32 m., greatest breadth 18 m.; area, exclusive of Dublin city, 348 sq. m., or 222,709 acres, of which 196,063 are arable; pop. in 1851, exclusive of the capital, 146,631. It has a coast line, including windings, of 70 m., comprising the natural harbors of Dublin bay, Killiney, Malahide, Rogerstown, and Lough Shinney, with harbors constructed by art at Kingstown, Howth, and Balbriggan. The rivers are the Liffey, Tolka, Dodder, and Bray. The general character of the surface is level, but on the S. boundary rises a range of hills, culminating in the peak of Kippure at a height of 2,473 feet, and separating the county from Wicklow. Near these extend the Dublin mountains, the central group of which is 1,000 or 1,200 feet high; toward the N. are picturesque valleys and cultivated heights, and on the coast are many bold promontories. The geological formation is mostly mountain limestone, bounded S. by a ridge of excellent granite. The soil is shallow, and in general not well adapted to agriculture, but careful drainage and manuring have rendered much of it productive. The principal crops are wheat, oats, barley, rye, potatoes, and turnips; the total extent of land under crops in 1855 was 108,746 acres. Grazing and the fisheries form important branches of industry. Lead and copper are mined to a small extent at Ballycorus. The manufactures are limited to stockings, cotton, and a few other fabrics. The channels of communication are the Grand and Royal canals from Dublin to the Shannon, and 4 railways radiating from the capital, viz.: the Dublin and Drogheda, the Great Southern and Western, the Midland Great Western, and the Dublin and Kingstown. The county returns two members to parliament.

DUBLIN, the capital of the above county and of Ireland, a municipal and parliamentary borough and seaport, at the head of Dublin bay, on both sides of the Liffey, lat. 53° 20′ 38″ N., long. 6° 17′ 29″ W., 292 m. W. N. W. from Lon-

don, and 63 m. W. from Holyhead; pop. in 1841, 232,726; in 1851, 258,361; at the same rate of increase it would reach in 1859 about 280,000 souls. The Liffey is navigable to the centre of the city, which is divided into two nearly equal portions. Its entrance is obstructed by a sand bar, on which at low ebbs there is not more than 9 feet water, although in spring tides it has 24 feet. At the mouth of this river in Dublin bay lies the harbor, formed by 2 piers or breakwaters, one projecting E. into the bay S. of the river, the other running out from the shore beyond Clontarf, N. E. of the city, and nearly meeting the former at an angle of 45°. The area thus enclosed at high water spring tides is 3,030 acres, and by systematic dredging the channel has been so deepened as to admit vessels of 1,400 tons. The wharves and docks connected with the custom house are capable of accommodating 40,000 tons of shipping, and 100 vessels can discharge at other quays on the S. There is a lighthouse at the end of the S. breakwater, and in other parts of the bay there are two other lights. A harbor of refuge has been constructed at Kingstown. The registered shipping of the port in 1856 was 501 vessels, tonnage 41,700; the entrances were 6,928 vessels, tonnage 913,062; clearances 3,881 vessels, tonnage 635,651. The trade of Dublin is chiefly with the midland districts, which it supplies with tea, coffee, sugar, tobacco, timber, deals, wines, and other foreign products, and with the English markets, to which it exports cattle and agricultural produce. With the United States its commerce is small, and confined mostly to timber. It has but few manufactures, and those of trifling value. Iron casting, cabinet making, and manufactures of the minor articles of jewelry and apparel, are thriving, but not to such extent as to afford employment to even a fraction of the population. Formerly 40,000 hands were engaged in silk weaving, but of late years this manufacture has dwindled away till it has now but 200 looms. The beautiful specimens of Irish poplins which were exhibited at the fair of 1853, gave rise to a demand for those fabrics, which has since increased. The well-known Dublin porter is an important item in the trade of the city, and the exports of it during the year ending May 4, 1855, were 87,905 hogsheads, nearly ½ being from the establishment of Guinness and co.—The modern part of Dublin is regularly built, without much architectural display, but with an appearance of substantiality and comfort. On the other hand, the lower part is occupied by filthy streets of wretched tenements, inhabited by a population as squalid as their dwellings. In hardly any other city are wealth and poverty in such close and marked contrast. The general aspect, however, to the stranger who follows the main thoroughfares, is very favorable. Generally speaking, the S. W. quarter is occupied by the poor, the N. W. by the middle classes, the S. E. and N. E. being the residence of the wealthy. The thickly populated part of the city has an extent of about 1¾ m. in each direction, but with the remainder it covers a space of 2½ by 2 m. It is well supplied with water, paved, and lighted with gas. Nine bridges, of which two are of iron, span the river, and an avenue called the Circular road, 9 m. long, encompasses the city. The public buildings are noted for their elegance. The bank of Ireland, in College green, was formerly used as the Irish parliament house. It is an extensive building, nearly semicircular in shape, with a fine Ionic colonnade. The apartment of the house of commons is now used as a teller's office, but the chamber of lords remains as when last used. Immediately opposite the bank is Trinity college, an imposing structure of the Corinthian order. It was founded under authority of Pope John XXII., closed in the time of Henry VIII., and reopened by Elizabeth, who incorporated it in 1592 as the college of the holy and undivided Trinity. It contains a small museum, and an extensive library, rich in ancient MSS. Trinity has a large faculty of professors, and at least 2,000 students. Two Roman Catholics were for the first time admitted to scholarships in 1856. The queen's university, incorporated by Queen Victoria in 1850, with power to confer degrees on students of the queen's colleges of Belfast, Cork, and Galway, holds the meetings of its senate at Dublin castle. The Roman Catholic university in Stephen's green was founded in 1854. Among the other literary and scientific institutions are the colleges of physicians and of surgeons, apothecaries' hall, and medical societies; the royal Dublin society, having museums of natural history and of agriculture, a botanic garden, a gallery of statues, a library numbering in 1857 over 30,000 volumes, a school of art attended by 484 students in 1857, and free lectures, attended by 22,036 persons in the same year; the royal Hibernian society of art, with an annual exhibition of paintings; the royal Irish academy of science, literature, and antiquities; the archæological society, society of engineers, mechanics' institute, statistical, geological, and zoological societies, with numerous other associations and reading societies, upward of 200 charity schools, and several libraries. An agricultural college, lately founded at Leopardstown, near Dublin, has a farm of 200 acres. The lectures in the recently established museum of Irish industry, with a government school of science applied to mining and the arts, were attended in 1857 by 6,416 persons, and the total number of visitors was 28,425. An act of parliament was passed, Aug. 10, 1854, to provide for the establishment of a "national gallery of paintings, sculpture, and the fine arts," for the care of a public library, and the erection of a public museum; and the first stone of the new building was laid in Dublin, Jan. 29, 1859. It will form a northern wing to the premises of the royal Dublin society, its gallery end facing Merrion square, and the corresponding southern wing will be devoted to the new museum. Although entitled the national gallery, it is also intended as a testimonial in commemoration of Mr. William Dargan's ex-

ertions in behalf of the great Dublin industrial exhibition of 1853. The probable cost of construction will be about £12,000. There were 28 newspapers and periodicals published in Dublin in 1858. The castle, the residence of the viceroy, stands on an elevation, but is not an imposing edifice. The Four Courts are a pile of building of Corinthian architecture, with a frontage on the Liffey of 500 feet, and occupied by the courts of queen's bench, chancery, exchequer, and common pleas. The custom house is altogether too extensive for the trade of the port; it is of the Doric order, and is surmounted by a cupola 125 feet in height. Other noticeable structures are the general post office, with an Ionic front, of considerable elegance; the city hall and exchange; commercial buildings, in which is the chamber of commerce; the queen's inns, linen hall, the weavers' hall, corn exchange, conciliation hall, the theatre, several barracks for constabulary and troops; Stephen's hospital for 300 patients; the Meath, city of Dublin, Sir Richard Dun's, and Richmond surgical hospitals, and royal hospital, designed by Sir Christopher Wren, for disabled soldiers; St. Patrick's hospital, erected from a legacy left by Dean Swift; lunatic asylums, infirmaries, foundling hospital, and a large number of benevolent institutions. Kilmainham, the county gaol, stands W. of the suburbs. Within the city are the Newgate, city and four courts, and marshalsea prisons, the bridewell, or house of correction, Smithfield penitentiary, penitentiary for females, and house of industry. Dublin is the seat of a Protestant and a Roman Catholic archbishopric, and has 2 cathedrals of the established church, those of St. Patrick and of the Holy Trinity, also called Christ's church, both of which are very ancient, and a modern Catholic cathedral. There are altogether about 75 churches, of which the established religion holds over 40, and the Catholics 9 or 10, beside 14 convents, and a house of the Jesuits. The cemeteries are: Goldenbridge for Roman Catholics; Prospect, 20 acres; Mount Jerome, 27 acres; Glasnevin, where O'Connell is buried. The "liberator's" friend has a tomb near him, with the epitaph "Honest Tom Steele." Curran is also buried here. Among the chief streets and public places of Dublin may be named Grafton street, passing into College green, in which is an equestrian statue of George III., and connecting by Carlisle bridge with Sackville street, where there is a column to the memory of Nelson; Dame street, containing many of the finest stores; St. Stephen's green, a square one mile in circumference, tastefully planted, and having a statue of George II.; College park, Fitzwilliam, Rutland, and Mountjoy squares. The celebrated Phœnix park comprises an area of 1,752 acres, and is the great resort of the people on gala days. A granite obelisk has been erected to Wellington on the left of the entrance. The Royal and Grand canals flank the city N. and S., and 4 railways open communication with Galway, Cork, Belfast, &c. Steam packets ply regularly to Holyhead, Liverpool, London, Bristol, Cork, Glasgow, &c. The environs of Dublin are remarkably beautiful. The bay, esteemed one of the finest in the United Kingdom, is 7 m. wide at its entrance, between Howth head and Kingstown, and extends inland about the same distance, with a somewhat increased width. The civic government is vested in a lord mayor, 15 aldermen, and 45 councillors. The city sends two members to parliament, and Trinity college likewise two.—Dublin claims a high antiquity. Curious Celtic remains were found in 1856 within the town walls of ancient Dublin. It is the *Eblana* of Ptolemy; Irish *Dubh-linn* (black pool); Danish *Dyflin*, and *Dyvelin*. In the early part of the 9th century it was taken by the Danes. The records of the next 3 centuries are little else than a succession of bloody battles. In 1169 it was taken by the English under Strongbow, who died and is buried there. In 1205 the castle was built; in 1190, 1282, 1283, 1301, and 1304, the city was burned; in 1405 the citizens made a descent on Wales for Henry IV. During the first half of the 16th century it was troubled by the Kildare family, one of whom, Lord Thomas Fitzgerald, among other exploits, murdered the archbishop. During Richard Cromwell's feeble protectorate the city was seized by the cavaliers, recovered by the parliamentarians, and again captured by the partisans of the king. In 1798 a conspiracy to seize the city and castle was frustrated by the arrest of Lord Edward Fitzgerald and others. In 1803 occurred Emmet's insurrection. Swift and Burke were natives of Dublin.

DÜBNER, Friedrich, a German philologian and critic, born in Hörselgau, Gotha, Dec. 21, 1802. In 1826 he was appointed professor in the gymnasium at Gotha, and during the 5 years that he held this position published philological articles in the periodicals, and especially made himself known by an edition of Justin. His principal studies, however, were upon the ancient comic authors, and he resigned his professorship in order to proceed to Italy to collate the original manuscripts. At this time he was invited by Didot to Paris to assist in preparing a new edition of Stephens's *Thesaurus*, a call which the valuable manuscripts contained in the Parisian libraries induced him to accept. He became employed upon the *Bibliotheca Græca* which Didot had undertaken, and his erudition gave to that splendid collection its completeness and scientific value. He alone contributed the critical editions of the *Moralia* of Plutarch, of Arrian, Maximus Tyrius, and Himerius, and the scholia to Aristophanes and Theocritus. He also took part in preparing the Parisian editions of St. Augustine and St. Chrysostom. Since 1842 he has published numerous school editions of the classics, and has been a frequent contributor to the *Revue de philologie* issued at Paris.

DUBOI, a town of Hindostan, in the province of Guzerat, district of Chumpaneer, 40 m. N. E. of Baroach; lat. 22° 8′ N., long. 73° 25′ E. It is surrounded by fortifications nearly 3 miles in circuit, and occupies the site of an ancient

Hindoo city, the ruins of which are still visible, and exhibit vast quantities of hewn stone, while the whole district, being of alluvial formation, furnishes scarcely a pebble.

DUBOIS, a S. W. co. of Ind., bounded N. by the E. fork of White river, and intersected by Patoka creek; area, 420 sq. m.; pop. in 1850, 6,321. It has a slightly diversified surface, and is covered with thick forests. The quality of the soil is good, and the staples are Indian corn and live stock. The productions in 1850 were 287,905 bushels of Indian corn, 38,590 of oats, 15,213 of wheat, 1,241 tons of hay, and 12,269 lbs. of wool. There were 5 grist mills, 6 saw mills, 2 tanneries, 8 churches, and 273 pupils attending public schools. Stone coal is abundant. Organized in 1818. Capital, Jasper.

DUBOIS, Antoine, a French surgeon, born in Gramat, department of Lot, June 18, 1756, died in Paris, March 30, 1837. While attending lectures on philosophy at the Mazarin college in Paris, he supported himself by giving lessons in writing, and afterward studied medicine under Desault, became the assistant of that eminent physician, and gradually rose to the head of his profession in France. He acted over 30 years as professor of clinical surgery and obstetrics; but with the exception of several remarkable articles which he contributed to the *Dictionnaire des sciences médicales*, he never reduced his system to writing. The *maison de santé*, which was founded by the government and of which he was nominated surgeon in chief in 1810, is known to this day as the Dubois hospital, in remembrance of his eminent services. He was a great favorite of Napoleon, whom he had accompanied to Egypt, and on the occasion of the birth of the duke of Reichstadt he attended Marie Louise.

DUBOIS, Guillaume, a French cardinal and minister under the regency of the duke of Orleans, born in Brives-la-Gaillarde, department of Corrèze, Sept. 6, 1656, died in Versailles, Aug. 10, 1723. He was the son of an apothecary, went at an early age to Paris, and studied there in one of the colleges, where he was employed as a valet by the principal. Subsequently he became a private teacher, and eventually tutor to the duke of Chartres. By flattering the passions of his young pupil, who afterward became regent of France, under the title of duke of Orleans, he paved the way for his own elevation. Dubois persuaded him to marry Mlle. de Blois, a natural but legitimized daughter of Louis XIV., and was rewarded with a rich abbey in Picardy, and sent on a diplomatic mission to England. On his return to Paris he acted as private secretary of the duke of Orleans; and afterward, when on the death of Louis XIV. the duke was invested with the regency of France, Dubois became a member of the council, and exerted a prominent influence upon foreign affairs. He concluded in 1717, in concert with Lord Stanhope, the famous triple alliance of France, England, and Holland against Spain. After becoming minister of foreign affairs, he succeeded in baffling the conspiracy of the Spanish ambassador Cellamare, which was instigated by the Spanish prime minister Alberoni, the object of which was to make Philip V. of Spain regent of France in place of the duke of Orleans. A war with Spain ensued, which resulted in the removal of Alberoni and the adhesion of Philip to the English, French, and Dutch treaty, which henceforth was called the quadruple alliance. Elated with his triumph, the ambition of Dubois knew no bounds, and it was fully gratified by his being appointed archbishop of Cambray, and eventually cardinal, prime minister, and member of the French academy. His administration of affairs was marked by a certain degree of vigor, and he was unquestionably a person of great ability; but his life on the whole presents a hideous array of selfishness and vices, and his nomination to high office in church and state belongs to the incidents which were characteristic of the dark history of France in the 17th and 18th centuries. When the operations of the Scotch financier Law brought the country upon the verge of universal bankruptcy, and while the regent was spending his time in pleasure and debauchery, Dubois availed himself of the disasters of France and the weaknesses of his master to amass an immense private fortune, his revenue amounting to 3,000,000 francs, beside the benefits accruing from the 7 abbeys of which he was the incumbent, independent of the see of Cambray. A record of his private life appeared in 1789, and his memoirs in 1817. Those published in 1829 are not authentic.

DUBOIS, Jean Antoine, a French abbé and missionary, distinguished for his services in India, born in Saint-Remèze, department of Ardèche, in 1765, died in Paris, Feb. 7, 1848. He spent 32 years in the East Indies, and on his return published "Letters on the State of Christianity in India" (London, 1823), which produced much controversy in England from the fact of his having frankly expressed therein his disbelief in the possibility of the conversion of the Hindoos. He wrote several remarkable works relating to the religion and the traditions of India, and many contributions to the *Bulletin des sciences*, and to the journals of the Asiatic societies of London and Paris, of which he was a member. His most celebrated work, entitled "Description of the Character, Manners, and Customs of the People of India, and of their Institutions, religious and civil," was purchased for £800 by the East India company, published at its expense in London in 1816, and afterward published in French under the title of *Mœurs, institutions, et cérémonies des peuples de l'Inde* (Paris, 1825).

DUBOS, Jean Baptiste, a French critic and historian, born in Beauvais in Dec. 1670, died in Paris, March 23, 1742. The best known of his numerous works is his *Histoire critique de l'établissement de la monarchie Française dans les Gaules* (3 vols. 4to., Paris, 1734). The theory which he maintains in this work, that the occu-

pation of Gaul by the Franks was a settlement and not a conquest, has been warmly contested by Montesquieu and others. Of his *Réflexions critiques sur la poésie et la peinture* (2 vols. 12mo., Paris, 1719; 6th ed., 1755), an English translation was published in London in 1748.

DUBS, Jakob, a Swiss statesman, born at Affoltern, in the canton of Zurich, in 1822, has gained distinction by his advocacy of reform in the administration of justice and in education, and written several valuable treatises on both subjects; has occupied various high functions in the government of his native canton; officiated in 1857 as president of the federal court, and from July 7, 1856, to the same date in 1857, as president of the federal council of states.

DUBUFE. I. Claude Marie, a French painter, born in Paris about 1790. He studied with David, and for many years attempted historical paintings on a grand scale, which met with little favor. In 1827 he exhibited 2 pictures of a sentimental character entitled *Les souvenirs* and *Les regrets*, which, in spite of much hostile criticism, became very popular through the medium of engravings. After executing several works of a similar character, he turned his attention to portraits, in which he has been successful. He painted the likenesses of many distinguished persons, including Louis Philippe and his daughter, the queen of the Belgians. A number of years ago two large pictures by Dubufe, representing the temptation and expulsion of Adam and Eve from paradise, were extensively exhibited in the United States. II. Édouard, son of the preceding, born in Paris about 1818, studied under his father and Paul Delaroche, and for some years followed the sentimental style of his father's *Souvenirs* and *Regrets* with success. Afterward he painted scriptural subjects, but of late years, following the example of his father, he has confined himself almost exclusively to portrait painting. Among his most successful recent works are portraits of the empress Eugénie, Rosa Bonheur, and of the members of the congress of Paris.

DUBUISSON, Paul Ulrich, a French author, born in Laval in 1746, guillotined March 23, 1794. He went when young to Paris, and wrote for the stage with small success. He was one of the most jealous of authors, and was accustomed to fill his prefaces with abuse of the contemporary writers who surpassed him, the actors who refused to flatter him, the journalists who jested at him, and the public who neglected him. Finally, he went to America, and subsequently to Belgium, whence he returned to France a few years before the outbreak of 1789. He embraced the cause of the revolution with enthusiasm, became associated with the Jacobin club, and having taken part in the schemes of Hébert, Ronsin, and Anacharsis Clootz, he shared the fate of those revolutionists. He published a number of tragedies and comedies, a volume of "Critical and Political Letters upon the Colonies of France," and a "History of the American Revolution."

DUBUQUE, an E. co. of Iowa, bordering on Illinois and Wisconsin, bounded N. E. by the Mississippi river, watered by Fall river and the Little Maquoketa; area, 600 sq. m.; pop. in 1856, 25,871. It has a hilly surface, clothed with extensive tracts of timber. The soil is adapted to Indian corn and wheat, which form, together with grass and dairy produce, the chief staples. In 1856 the productions were 12,779 tons of hay, 233,931 bushels of wheat, 236,108 of oats, 564,236 of Indian corn, 124,457 of potatoes, and 178,574 lbs. of butter. Dubuque county is one of the richest mineral regions of Iowa, and yields annually vast quantities of lead. Limestone underlies most of the surface. The county was named in honor of Julien Dubuque, by whom the lead mines were first worked. Capital, Dubuque.

DUBUQUE, the largest city of Iowa and seat of justice of Dubuque co., situated on the right bank of the Mississippi, directly opposite the boundary line of Wisconsin and Illinois, and 450 miles N. of St. Louis; pop. in 1850, 3,108; in 1854, 6,634; in 1856, 15,000; in 1859, estimated at 17,000. It is the oldest town in the state, having been first settled by white men in 1788, when Julien Dubuque, a French Canadian, under a grant from the Spanish government, commenced operations in the lead mines on the present site of the city. Its permanent settlement commenced in June, 1833, when the U. S. government took possession of the land, which the Indians by treaty had vacated the year before. Before the end of the first year of its settlement it had a population of about 500. A town government was organized in 1837, and a city charter was adopted in 1841. In 1838 its "corporation tax" was $524; in 1858, upward of $100,000. The assessed value of the real and personal property is $8,000,000. The business part of the city is situated on a plateau of land about ¾ of a mile wide, narrowing to a point a mile below the centre of the city. This plateau has a gradual ascent to the base of the bluffs, which are steep and rise to the height of more than 200 feet. Ravines here and there lead up through them into the open and undulating country. Beautiful houses of unusual size and finish stand upon their summits, in the midst of a young growth of shrubbery. In front of the city are sloughs, which are being filled by the enterprise of 3 wealthy improvement companies, and thus the extent of the business quarter will shortly be nearly doubled. The land is mostly of a gravelly nature, is therefore generally dry, and hence the city is remarkably healthy. Dubuque has the largest and best constructed school houses west of the Mississippi, and its public schools are modelled on the graded system. It has also Alexander college, a female college, and several private schools, Protestant and Catholic. It has 1 Baptist church, 1 Christian, 1 Congregational, 3 Roman Catholic, 1 Lutheran, 3 Methodist (including 1 German), 2 Presbyterian, and 1 Universalist. It has a branch of the state bank and several

banks of deposit. A U. S. building designed for a custom house, post office, &c., is in process of erection; the material employed is a beautiful stone from quarries near Nauvoo, Ill. The city has been lighted with gas since the summer of 1855. The Illinois central railroad terminates at Galena, opposite Dubuque; the Milwaukee and Mississippi railroad is gradually approaching Dubuque; the Dubuque and Pacific railroad is in progress westward, being already open to Nottingham, 39 m. distant; the Dubuque western is open to Anamosa in Jones co., 40 m. S. W.; the Dubuque and Bellevue is in course of construction southward along the right bank of the Mississippi; and the Dubuque, St. Paul, and St. Peters, and Dubuque and Turkey Valley roads, are projected. Commercially, the situation of the city is advantageous. Lying on the Mississippi, the great natural outlet of all the states on its western side, and being the radiating point of several railroads, it must speedily become the great shipping port north of St. Louis. The agricultural and mineral products of the northern half of Iowa, the lumber from Wisconsin, and almost every other article of traffic in western commercial towns, is here seeking a market or the facilities for transshipment. The value of merchandise exported in 1854 was $1,573,408, and of that imported $4,933,208; the value of exports in 1855 was $3,689,266, and of imports, $11,266,845. In 1856 the imports of dry goods amounted to $3,595,200, and the sales and exports to $3,749,547; the imports of groceries to $3,423,000, and the sales and exports to $3,936,450. The next in importance of the articles of commerce were hardware and iron (sales and exports, $1,109,475), clothing ($332,720), boots and shoes ($298,071), and drugs and chemicals ($247,118); amount of lumber imported, 89,440,880 feet; number of shingles, 8,984,000. The Dubuque and Dunleith ferry company has 2 steam ferry boats, one of which plies constantly. The Dubuque and Minnesota packet company has a line of 15 steamboats engaged in the upper Mississippi trade; two of them leave Dubuque daily for St. Paul. The city has 3 daily newspapers, 2 tri-weekly, 1 semi-weekly, 5 weekly, and 1 monthly. Measures are in progress for the construction of water works. Establishments for the manufacture of shot, white lead, threshing machines, reapers, steam engines, mill machinery, &c., are in operation. The lead mines of Dubuque have yielded fortunes to hundreds of men, and yet the task of working them is but just begun. Several very rich "leads" were struck in the summer of 1858. Mining companies have recently been formed, and with organized capital and suitable machinery the work of mining will be carried on more extensively and to much better advantage. Zinc is also abundant in the city limits, and will one day be rendered a source of wealth.

DU CANGE, Charles du Fresne, a French historian and philologist, born in Amiens, Dec. 18, 1610, died in Paris, Oct. 23, 1688. He was educated in the Jesuits' college in his native city, and at the age of 13 spoke and wrote Greek and Latin freely. In 1631 he was admitted as an advocate before the parliament. From that time, however, he gave himself up to literature, and in 1678 produced his first and one of his most useful works, the *Glossarium ad Scriptores Mediæ et Infimæ Latinitatis* (3 vols. fol., Paris), a new edition of which, in 7 vols. 4to., appeared in Paris in 1844. As a companion to this, he published a glossary of the impure Greek of the middle ages (2 vols. fol., Paris, 1688). Both are works of the highest value to the student of mediæval history, and the former was augmented by the Benedictines, who added to it at different times 7 volumes. Du Cange also produced a *Traité historique du chef de Saint Jean Baptiste* (4to., 1665); an annotated edition of De Joinville's *Histoire de Saint Louis IX.* (fol., 1668); and a *Historia Byzantina illustrata* (Paris, 1680). His published works, however, comprised but a small part of his labors. His MSS., the voluminousness of which is almost incredible, have been collected and catalogued in the university of Paris, and measures have been taken for their publication in Paris. A monument to this profound scholar was erected in Amiens in 1850.—See *Essai sur la vie et les ouvrages de Du Cange*, by Léon Feugère (Paris, 1852).

DUCAREL, Andrew Coltee, an English antiquary, born in Normandy in 1713, died in London, May 24, 1785. He was educated at Eton, and at St. John's college, Oxford, and made a journey to Normandy in 1752, which supplied materials for a work entitled "Anglo-Norman Antiquities" (first published in 4to. in 1754; enlarged and republished in fol., London, 1767). He thus opened the way for other learned antiquaries of his country, who during the past century have frequently visited and described the religious monuments of a province where so many traces of connections between Norman and English families exist. His work was received with great favor, and though subsequent researches have proved the inaccuracy of some of its statements, yet it is still valued for the materials which it contains. It has descriptions and representations of some monuments since destroyed. In 1762 he was elected a member of the royal society, and the next year he was appointed, with Sir Joseph Ayloffe, to put in order the state papers at Whitehall. It was his custom annually to travel incognito with one of his friends during the month of August, taking with him Camden's "Britannia" and a set of maps, and thus to examine minutely all places of interest. Among his other publications were a "Series of more than 200 of the Anglo-Gallic Coins of the Ancient Kings of England, illustrated in 12 Letters" (4to., London, 1757); the "History and Antiquities of the Archiepiscopal Palace at Lambeth;" and numerous papers in the "Philosophical Transactions."

DUCAS, Michael, a Byzantine historian of the 15th century. He was a descendant from an

imperial family, and himself held a high position at the court of Constantine Palæologus, the last emperor of Constantinople. After the conquest of that city by Mohammed II. he took refuge with the prince of Lesbos, Dorino Gateluzzi, and was appointed by him and his successors to various diplomatic missions. He accompanied his master to Constantinople, when he went to do homage to the sultan, and his prudence and skill succeeded in saving the independence of Lesbos. Under Nicholas Gateluzzi, however, the wrath of Mohammed was called down upon the island, and it was united in 1462 to the Ottoman empire. Though Ducas survived this event, nothing more is known of his life. It is probable that he retired to Italy, and wrote in his old age the history which has come down to us. This work, divided into 45 chapters, begins with an outline of universal chronology, and does not become detailed and truly instructive till the reign of John Palæologus I., and it terminates abruptly in the middle of a sentence, at the capture of Lesbos in 1462. It is the most difficult of all the Byzantine histories, written in a barbarous style, but is judicious and impartial.

DUCAT, a gold coin, which has been long in circulation in a large part of Europe. The first ducats are said to have been struck in the 12th century in Sicily by Roger II., and to have received their name from the device which was inscribed upon them: *Sit tibi, Christe, datus, quem tu regis, iste ducatus.* A little later ducats of various kinds became current in Italy, and especially in Venice; and they spread thence through Switzerland, the Germanic states, Russia, Sweden, Denmark, Holland, and Spain. In Spain, however, at present, the ducat is only a money of exchange. In Germany the ducats, being made in 1559 a legal coin of the empire, soon displaced the gold florins, and were generally struck with the likeness of the sovereign princes upon them. The ducats of Austria and Holland are the only ones which have acquired a very extensive circulation. Those of Holland are the most widely spread, bearing an emblem of a knight armed cap-a-pie. This emblem was for a short time exchanged for the likeness of King Louis of Holland. The value of the ducat varies somewhat in different countries, but it is generally little more than that of 2¼ American dollars. There are also silver ducats in France and Spain, having half this value. (See Coins.)

DUCHÂTEL, Charles Marie Tanneguy, count, a French economist and politician, born in Paris, Feb. 19, 1803. Prior to 1830 he took an active part in editing the *Globe*, one of the leading organs of the liberalists. In 1827 he published a work on pauperism, which competed unsuccessfully for the academic prize, and in which he showed himself a disciple of the principles of Malthus, and proposed as a remedy for the sufferings of the poorer classes the formula of "labor, economy, and prudent marriages." He began his parliamentary career in 1832, was named secretary-general of the finances in 1833, and in 1835 was appointed to the ministry of commerce. He resigned with his colleagues in Feb. 1836, but became a member of a new cabinet 6 months later as minister of the finances The new *doctrinaire* ministry, however, was soon overthrown, being followed by the administration of Molé, and Duchâtel now became one of the most energetic leaders of the opposition. At the accession of the cabinet of Soult and Guizot in 1840 he came again into power as minister of the interior, and retained this position with but a short interruption till the revolution of 1848, since which he has lived in retirement. The measures supported by him both as deputy and minister were generally of a financial character, but he also took a prominent part in the establishment of railways and telegraphs in France.

DU CHÂTELET, Gabrielle Émilie (Le Tonnelier de Breteuil), marchioness, noted for her intimacy with Voltaire, and for her literary attainments, born in Paris, Dec. 17, 1706, died in Lunéville, Aug. 10, 1749. She was married at an early age to the marquis du Châtelet-Lomont, and afterward divided her time between science and dissipation, in both of which she became a proficient. Not even a love affair with the fascinating duke de Richelieu could withdraw her from her studies. In 1733 she became the mistress of Voltaire, and the next year removed with him to Monjeu near Autun, and afterward to the château of Cirey, where the marquis extended to her paramour the indulgence he had always shown to herself. Here they passed several years in unrestrained freedom, both actively engaged in literary pursuits, especially in the study of the English philosophers, Newton and Locke. The marchioness composed her *Dissertation sur la nature et la propagation du feu; Institutions de physique*, a synopsis of Leibnitz's philosophy, and various other essays; while Voltaire wrote *Le siècle de Louis XIV.*, *Mérope*, *Alzire*, and *Mahomet*. During a visit to the court of Stanislas, the ex-king of Poland, at Lunéville, the faithless lady fell in love with the marquis de Saint Lambert, a captain in the guard, by whom she had a daughter, and a few days after giving birth to this child she died at the palace of Lunéville. Several of her works were published posthumously, including *Principes mathématiques de la philosophie naturelle* (translation of Newton's *Principia*, with a commentary, 1756); *Doutes sur les religions révélées, adressés à Voltaire* (8vo., Paris, 1792); *Lettres inédites à M. le comte d'Argental* (12mo., Paris, 1806).

DUCHÉ, Jacob, an American clergyman, born in Philadelphia in 1739, died there in Jan. 1798. He was graduated at the college of Philadelphia, afterward the university of Pennsylvania, in 1757, and completed his education at Cambridge, England. In 1759, having received a license from the bishop of London, he was ordained an assistant minister of Christ church in Philadelphia, of which in 1775 he became rector. He was a man of brilliant talents and impressive eloquence, and at the meeting of the second congress in 1775, just after the outbreak of the war

of the revolution, he was invited to open the congress with prayers. By sermons delivered before congress, and before the patriots of the army, he established his character not only for eloquence but for patriotism; and being in 1776 chosen chaplain to congress, he resigned his salary for the relief of the families of those patriots who had fallen in battle. Yet he lost confidence in the cause of independence, and in 1777 addressed a letter to Washington in which he pictured the hopelessness of resistance, and urged him to cease his desperate and ruinous efforts. Washington transmitted the letter to congress, and, Duché having fled to England, his estate was confiscated as that of a traitor. He returned to America in 1790, but never regained influence or position. He published while in London 2 volumes of sermons, written in an easy and elegant style, which passed through several editions. His wife was a sister of Francis Hopkinson, and his daughter married John Henry, whose political manœuvres in 1812 caused some excitement. The literary character of Duché has been variously estimated. Wharton and Graydon term him weak and vain; Sabine attributes to him brilliant talents, impressive oratory, and fine poetic taste; while all unite in denouncing him, in the language of John Adams in 1777, as "an apostate and traitor."

DUCHESNE, André, a French historian, whose labors gained him the title of the father of French history, born in Isle Bouchard, Touraine, in 1584, died in 1640. He was geographer and historiographer to the king, and died by being crushed under a cart, while on his way from Paris to his country seat. Beside his published works he left more than 100 volumes in MS. Among the most important of the former are *Historiæ Normannorun Scriptores Antiqui* (fol., Paris, 1619); *Historiæ Francorum Scriptores* (fol., Paris, 1633–'5); and some genealogical histories.—His son, François, born in 1616, died in 1640, was also historiographer to the king, and wrote a history of the popes (2 vols. fol., Paris, 1653).

DUCHESNE DE GISORS, Jean Baptiste Joseph, a French painter, born in Gisors, department of Eure, Dec. 8, 1770, died there, March 25, 1856. He removed to Paris at an early age, and made himself prominent in 1812 by a remarkable portrait of Napoleon. After the restoration of the Bourbons he became court painter. His miniature of the duchess de Berry is considered a unique specimen of the art. He was much employed by the royal families of England and Belgium, and between 1840 and 1848 was engaged in executing a commission from the French government to continue the series of paintings on enamel in the Louvre commenced by Petitot. He also executed a series in enamel for Queen Victoria after the miniatures of Sir William Ross. Some of the latter, painted in his 82d year, are of the highest excellence.

DUCIS, Jean François, a French poet, born in Versailles, Aug. 22, 1733, died there, March 31, 1816. He made his first appearance in the literary world as the author of the unsuccessful tragedy of *Amélise*. He afterward adapted several of the plays of Shakespeare to the French stage, and in this had considerable success. Of his original dramatic works the best is his *Abufar, ou la famille Arabe*. In the latter part of his life he wrote some shorter poems which are graceful and sweet. He was an adherent of the Bourbons, and refused the place of senator, with 50,000 francs a year, offered him by Napoleon, though he was at the time in great poverty. His works were published at Paris in 1819 in 3 vols.

DUCK, a name applied to birds of the family *anatidæ*, of the order *anseres* or *natatores*. The familiar external characters are a large flattened bill, covered with a soft epidermis rather than horn, and with its sides armed with lamellæ or small teeth-like processes; the tongue is fleshy, with dentated margins; the wings are moderate; the feet at or near the centre of equilibrium; the anterior toes joined by a web; the neck is long. The number of vertebræ is large, especially in the neck; the sternum and pelvis are large and wide, the former with a well developed keel, and posteriorly with 2 openings or deep indentations; the fibula is not entirely anchylosed to the tibia. The gizzard is fleshy and large; the intestines are about 5 times as long as the bird, and the cæcal appendages often ⅓ as long as the body; the trachea and inferior larynx generally bulbous. The ducks are divided into 3 subfamilies, *anatinæ* or river ducks, *fuligulinæ* or sea ducks, and *erismaturinæ* or spiny-tailed ducks. I. The *anatinæ* have the bill equal in width and height, depressed at the tip, which has a hard nail, and the inner portion of the lateral margins lamellated; the tarsi are compressed, and generally as long as the inner toe; the hind toe is bordered with a slight membrane from base to tip. These ducks prefer fresh water, feeding along the edges of streams rather than diving, eating small mollusks and soft aquatic plants; some feed on the land, and roost and build their nests in trees; they are powerful fliers, and have a wide geographical range. In the genus *dafila* (Leach) is the pin-tail duck (*D. acuta*, Linn.), having the bill lead-colored with a black spot at the tip, a long slender neck, the wing speculum of a purple or coppery red with deep green reflections and black border, the feathers with broad white tips, and a long and pointed light gray tail, dark brown in the middle; in the adult male the head, cheeks, throat, upper part of front neck, and sides are dark brown; a small part of hind neck dark green, almost black; the upper parts in general undulated with narrow bars of brownish black and yellowish white; wings grayish; upper tail coverts cream-colored; an oblique white band on the side of the neck; lower parts white, undulated like the back or the sides, and lower tail coverts black, white-edged at the side. The female and young are variegated with brown and brownish white; the speculum is dusky green, and the long tail feathers are

wanting; they are sometimes called gray ducks. The male is about 29 inches long to end of tail, extent of wings 36 inches, weight about 2 lbs.; the females are smaller. It is most commonly seen on the inland ponds of the west and south of the United States from early autumn to spring, in company with teals, widgeons, and mallards; the breeding place is in the far north, in passing to and from which the birds are seen on the coast. They are very graceful on the water, rarely dive, and are less shy than most others of the family; a favorite article of food is the beech nut; they will also eat tadpoles, leeches, insects, and even dead animal matter; the flesh is much esteemed for food. Several species are found in South America, Europe, Africa, and Asia, migrating to temperate regions from the north. The typical genus *anas* (Linn.) includes the mallard or common wild duck, the origin of the domesticated species. The mallard (*A. boschas*, Linn.) has a bright purple speculum with green reflections and black border, the secondaries broadly tipped with white, and the secondary coverts with white ends and black border; the head and neck deep green, a white ring around the middle of the neck; the breast reddish brown; fore part of back light brown, the rest darker, and rump black with green reflections; upper surface of wings grayish brown; sides and lower parts pale gray with dusky bars; the length is about 24 inches, extent of wings 36, and weight 2½ to 3 lbs.; the females are smaller, of a brownish color, with a less brilliant speculum and the head and neck with dusky streaks. This species is smaller but more beautiful than the domestic races which have sprung from it; the wild bird may be known from the tame by its soft and pliable feet, which in the latter become hard and wider from walking over gravel and roads. The mallard is found abundantly from New York southward and westward, being replaced to the northward, according to Audubon, by the velvet duck (*oidemia fusca*, Linn.); it is rarely seen on salt water, except when migrating. The flight is strong and rapid, easily commenced from land or water; when alarmed it utters many loud quacks; it is truly omnivorous, devouring any thing eatable, even carrion and small animals that come in its way; beside man, its principal enemies are hawks and owls, the raccoon, lynx, and the snapping turtle. The flesh of the young birds is much esteemed; the large hybrids produced from the mallard and Muscovy duck are excellent for the table; this species also breeds with the black duck and the gadwall, the latter hybrid being very handsome, retaining the yellow feet and barred plumage of the one and the green head of the other parent. The black or dusky duck (*A. obscura*, Gmel.) is so called from its general dusky plumage; the speculum is green, with purple reflections and black border, and the secondaries are tipped with white. In shape and habits it resembles the mallard, and no doubt could be easily domesticated; the flesh of the young birds is excellent, and the feathers are soft and elastic. The shoveller duck (*spatula clypeata*, Linn.), or spoon-bill as it is called by sportsmen, has the bill twice as broad at the end as at the base, much rounded, with the sides at the base so closely pectinated as to resemble the teeth of a fine comb; the head and neck are glossy green, upper part of breast white, rest of lower parts chestnut, except the lower tail coverts, and a black band across the vent; sides yellowish with dark pencillings; secondaries greenish, the inner with terminal white spots; primaries dark brown, with white shafts; lesser wing coverts light blue; speculum golden green; rump greenish black, white at the sides; tail dark brown, with pointed feathers broadly edged with white; length about 21 inches, extent of wings 32, weight 1½ to 1¾ lbs. It associates with teals, mallards, and gadwalls, and is omnivorous; its flesh is much prized, and Audubon says that no sportsman who is a judge will pass a shoveller to shoot a canvas-back; it is comparatively a rare duck, and is most common in the southern and western states. The Australian genus *malacorhynchus* (Swains.) is nearly allied to the shoveller. The Muscovy duck (*cairina moschata*, Linn.), more properly called musk duck, is distinguished by the rounded red tubercle or carbuncle on the top of the bill at the base; the color is glossy black, with the wing coverts white; by its lobed hind toe it connects the river ducks with the next subfamily. It is of large size, being about 33 inches long; it has an odor of musk, proceeding from the coccygeal glands, which is communicated to the flesh; in its pure state it is difficult to raise, but it breeds well with the mallard, and in this domesticated state its plumage is more white, and the musky odor is absent. It is supposed to have originally come from South America, whence it has spread over the world. To the river ducks belong the genera *tadorna* (Leach), the European sheldrake, this name in America being applied to a merganser; *aix* (Boie), the wood or summer duck; *mareca* (Steph.), the widgeon; *querquedula* (Steph.), the green-winged teal; *pterocyanea* (Pr. Bonap.), the blue-winged teal; and *chaulelasmus* (Gray), the gadwall; these will be described under their respective common names. II. The sea ducks, or *fuligulinæ*, have the bill higher than broad, depressed at the tip, which is armed with a broad strong nail; the wings are moderate and pointed, the tail generally short and wedge-shaped, the tarsi compressed and much shorter than the middle toe; the toes long and united by a full web, the outer as long as the middle; the hind toe short, with a deep membranous web. These ducks are generally marine, feeding on mollusks and small fish, which gives to their flesh a strong flavor; most are excellent fliers. The genus *fuligula* (Steph.) includes the scaup duck and the ring neck. The scaup duck (*F. marila*, Linn.) has the head, neck, fore part of back, and breast black, glossed with purple and green, and the last two tinged with brown; the rest of the upper parts and ab-

domen brownish black; the middle back, scapulars, secondaries, front of abdomen, and sides grayish white, with undulating fine black lines; middle of breast white; wings light brownish gray; speculum on the brownish black secondaries white; the length is about 17 inches, extent of wings 29, and weight 1½ lbs.; the females are more brown and white. This duck, which is called broad-bill and blue-bill, is found along the Atlantic coast and also on the western rivers; it arrives from the north in October in large flocks, which at first may be easily decoyed; when wounded, it is very difficult to obtain on account of its diving, and from its fishy taste is hardly worth shooting; its flight is rapid and high. The ring-necked duck (*F. rufitorques*, Pr. Bonap.) has a tufted head, which with the upper neck is greenish black, with purple reflections; on the neck is a brownish red ring, widest in front; a triangular white spot at the base of the lower mandible; upper parts generally brownish black, lower parts grayish white; outer secondaries with slate-colored webs, tipped with white; tail brownish gray; the length is about 18 inches, and the extent of wings 28. The female has a white band on the forehead, upper parts brownish, below white. It is met with on the coast and in the interior; it swims, dives, and flies well; its flesh is said to be excellent, not having the fishy flavor of the scaup duck. Other species of the genus are found in the northern parts of Europe and Asia, and one in New Zealand; the European tufted duck is the *F. cristata* (Linn.). The genus *nyroca* (Flem.), including the canvas-back (see Canvas-Back), which by some authors is put in the preceding genus, is represented here also by the red-head (*N. ferina*, Linn.); this species has a bluish bill, black toward the end; in general appearance it resembles the canvas-back, except that the head and upper neck all round are dark chestnut, and the back is grayish brown, barred with fine white lines; the length is 20 inches, extent of wings 33, and weight 2½ lbs.; in the female the head and neck are brown like the back. The red-head, like the canvas-back, is very common in the Chesapeake, but is rare north of New York; its flesh is as good as that of the canvas-back, and it is often sold for it to the inexperienced; it arrives about November, leaving for the north to breed in early spring. The genus *clangula* (Flem.) contains several well known species, among them the golden-eyed duck (*C. Americana*, Pr. Bonap.); this bird has a black bill, with a white spot between the base and eye; head with a crest of feathers more than an inch long; iris bright yellow; head and upper neck rich green with purple reflections; rest of neck and plumage generally white; back and wings blackish, with a patch of white on the latter formed by the secondaries and tips of the coverts; sides of rump grayish; the length is 20 inches, extent of wings 31, and weight about 2¼ lbs.; the female is dull brown above, white below, with dusky wings. This species arrives with the other sea ducks in the autumn from their breeding places in the north; it is found from high arctic latitudes to Florida, both on the coast and in the interior; its food consists of mollusks, crustaceans, and small fish, which it procures by diving. Its flight is strong and very rapid, and accompanied by a sound which has caused this bird to be called whistler; the flesh has a fishy taste, which is relished by some; though shy and difficult to approach, it will generally alight at the decoys of the gunner on the coast. The buffel-headed duck (*C. albeola*, Linn.), or spirit duck, is a miniature representative of the golden-eye; the bill is blue; the head crested; a patch behind the eye, going over the head, and band on the wings, white; rest of head and hind neck glossy green, with purple reflections; fore neck, breast, and sides pure white; abdomen dusky white; tail and upper coverts grayish brown; back and wings black, the latter with a white patch; the length 14½ inches, extent of wings 23, weight 1 lb.; the female is sooty brown above, breast and abdomen soiled white, fore neck ash-colored, with a white band on the sides of the head. This duck receives its common name from the disproportionate size of the head compared with the body; from its diving habits it is also called dipper; the flight is very rapid, and its distribution extensive; its flesh is fishy. The harlequin duck (*C. histrionica*, Linn.) is a beautiful and singularly marked species, and much prized as a cabinet specimen; the bill is yellowish olive; a broad black streak passes over the top of the head, margined with reddish brown; front of the eye and a spot behind it white; a slightly curved white line on the neck; sides of head and neck purplish blue; a complete ring of white below the middle of the neck; a band of white in front of the wing, passing on the breast, edged with black; fore back light blue, becoming black behind; scapulars white, and secondaries tipped with the same, forming a bar on the wings; fore breast light blue, abdomen brownish; quills dark brown, tail grayish black; under the tail at base a white spot; the length is 17 inches, extent of wings 26½, and weight 1½ lbs.; the female is grayish brown. It is rare on the coast south of Massachusetts, but common to the north, especially in the British provinces; it is shy, an excellent flier and diver, difficult to obtain, and not much prized as food. The long-tailed duck (*heralda glacialis*, Linn.), called also "old wife" and "old squaw," has the bill black at the base, orange yellow at the end, with a bluish gray nail; iris carmine; a grayish white patch from the bill to behind the ear; upper part of head and nape black, narrower in front; neck all round and fore breast chocolate-brown; back and wing coverts brownish black; scapulars margined with light brown. This is the male summer plumage; in winter, the head, neck, fore back, and scapulars are white; upper parts brownish black, as are the 4 middle tail feathers; lower parts and the outer tail feathers white. The 2 median tail feathers extend several inches

beyond the others; length to end of tail feathers 23 inches, and extent of wings 30. The feathers are dense and blended, enabling the bird to resist the extreme cold of the arctic regions; in the winter it is found in all the Atlantic districts; it is timid, a swift flier and ready diver; the flesh is tough and fishy. The pied duck (*camptolaimus Labradora*, Gmel.) has the wing coverts and secondaries white, forming a large patch on the wings; the cheeks are furnished with bristly feathers; the bill is orange at the base, black at the end, with the sides of the upper mandible very thin, and the under deeply serrated; a black band on the top of the head; rest of head and upper neck white; in the middle of neck a broad black ring, the same color passing down the back; lower neck white; upper breast and sides black; lower plumage brownish black, as are the primaries and their coverts; the length is 20 inches, extent of wings 30, and weight nearly 2 lbs.; the female is bluish gray above, ash-gray below, with secondaries and sides of head white. This species, called the skunk and sand-shoal duck, does not seem to go further south than Chesapeake bay; it is essentially a marine bird, rarely entering rivers; it procures by diving over sand bars shellfish and small fry; its flesh is not considered a delicacy. The genus *somateria* (Leach) contains the eider and the king duck, which will be described under the former title. The genus *oidemia* (Flem.) includes those sea ducks which are erroneously called coots in New England. The velvet duck (*O. fusca*, Linn.) has the plumage generally black, with a spot under the eye and a large patch on the wings, formed by the secondaries, white; hence the name white-winged coot; the base and sides of the bill black, the sides bright red, and the nail orange or flesh-colored; iris bright yellow; the length is 22 inches, extent of wings 39, and weight about 3½ lbs.; the female is sooty brown, the lower parts lighter. These birds are seen in large flocks in the autumn along the Atlantic coast, when they are shot in great numbers from boats stationed near the shore; on account of the density of the plumage they require a heavy charge to kill them; though breeding in lakes and rivers, they are rarely seen during migration away from the sea. The flesh is dark, with a fishy flavor, but is relished by some persons. The surf duck (*O. perspicillata*, Linn.) has a bill of a reddish orange color, paler on the sides, with a black patch at the side of the base of the upper mandible; the plumage is black, except a white patch on the crown and hind neck; the eyes white; legs and feet reddish orange; the length is 20 inches, extent of wings 33, and the weight 2½ lbs; the female has a brownish tinge to the black plumage. This is also called coot, and associates with the preceding species, which it resembles in its habits; it is frequently called black duck; it is shy, and difficult to shoot except on the wing; the flesh is tough and fishy. The American scoter, or butter-bill coot, has a bill of a deep orange color at the base and black at the end; the general color of the plumage is black, bluish on the hind neck, the scapulars tinged with green; tail graduated; the length is 19 inches, and the extent of wings about 32. This associates with the other species of the genus. The *O. nigra* (Linn.) is a European bird. It is probable that the American scoters, like other birds breeding in the far north, are occasionally seen in Europe. III. The spiny-tailed ducks, *erismaturinæ*, have the bill elevated at the base and depressed at the tip, with a nail; the wings are short and concave, with the ends of the quills incurved; the tail is lengthened, of narrow, rigid feathers, slightly protected with coverts above and below; the tarsi are shorter than the middle toe, compressed; the toes long, united by a full web, the hind toe long with a broad web. These ducks are short fliers from the smallness of their wings, and their geographical distribution is not extensive. In the genus *biziura* (Leach), peculiar to Australia, there hangs from the lower mandible a large compressed wattle; the wings are very short, and furnished with 2 blunt tubercles at the shoulder. The best known species is *B. lobata* (Shaw). The ruddy duck (*erismatura rubida*, Wils.) has a grayish blue bill, the iris hazel, and the eye situated very high up; upper part of the head black, terminating in a point behind; sides of the head white; chin with a yellowish brown tinge; upper parts and sides reddish brown; lower parts white, with dusky bars; the tail black, short, and rounded; wings blackish brown; the length is 15 inches, extent of wings 22, and weight 1¾ lbs. The plumage varies much at different ages. It is common in Chesapeake bay, where it is called salt-water teal; it is found all along the coast and on the Ohio and Mississippi rivers. It is an excellent diver, but is by no means shy; when young and fat the flesh is tender and of good flavor. The saw-bill ducks will be described under MERGANSER, to which subfamily they belong.—The domestic duck is derived principally from the mallard, mixed in some cases with the musk duck and the gadwall, and perhaps the black duck. The variety considered the best here is the Aylesbury duck, from the town of that name in Buckinghamshire, England; many thousand pounds sterling worth of ducks are sent annually to London from this place, and almost all the broods are hatched under hens, as being more certain sitters; the most prized are pure white, with pale bill and legs. The advantages of this breed are their great size, easy management, and productiveness; they are early layers and good hatchers, and easily raised; beside, they are ornamental, with fine, white, downy feathers, pure skin, and white, delicate, and savory flesh; from their size they are the most profitable; at the age of 8 months a pair should weigh from 10 to 12 lbs. The large Rouen duck, originally from France, very prolific in eggs, is about 30 inches long; the back is sooty black; it is generally believed to be a half domesticated

species escaped from man's restraint, and afterward again subjected to him; it breeds readily with the common variety. Other varieties are the Flemish crested, black and white Poland, and Silesian ducks; the musk duck is a distinct species. The Chinese are famous for rearing immense numbers of ducks, which are hatched by artificial heat applied to the eggs placed in boxes of sand; they are fed with boiled crawfishes and crabs cut in small pieces and mixed with boiled rice; they are kept in boats, 300 or 400 in each, going out to feed in the morning and returning when wanted at the voice of their master. When it is considered that many thousand boats, each the residence of a family, crowd the river near Canton and other Chinese cities, an idea of the immense number of the ducks may be formed. In many parts of India a large and profitable trade is carried on in these birds. Tame ducks are in general easily reared, as, being omnivorous, they pick up a great part of their own living for a large part of the year. As the duck is generally a careless mother, a hen is almost always made to hatch out the ducklings, and most persons are familiar with the anxiety of the foster mother when her young brood takes to water for the first time. As a general thing the rearing of ducks is considered less profitable than that of other poultry.

DUCKWORTH, Sir John Thomas, an English admiral, born in Leatherhead, Surrey, Feb. 28, 1748, died in Plymouth, April 31, 1817. He entered the navy in 1759, was made a lieutenant in 1770, a post-captain in 1780, and in the action of June 1, 1794, in which the French fleet was defeated by the English squadron under Lord Howe, commanded a 74-gun ship. In 1798 he contributed to the conquest of the island of Minorca, and in 1799 was made rear admiral. Having afterward become vice-admiral, he defeated a French fleet in the bay of St. Domingo in 1806, for which he received the thanks of both houses of parliament, an annuity of £1,000 a year, and other rewards. He sat for a time in parliament, was governor and commander-in-chief of Newfoundland from 1810 to 1815, and on his recall to England was appointed governor of Plymouth. He was made a baronet in 1813.

DUCLOS, Charles Pineau, a French author, born in Dinan, Brittany, Feb. 12, 1704, died in Paris, March 26, 1772. He studied in Paris, at first with a view to the law, but his tastes and association with the prominent wits of the day inclined him to the pursuit of letters. The first work which gained him reputation was his *Histoire de la baronne de Luz* (1741), the success of which was equalled or surpassed by that of the *Confessions du comte de* * * *, published the next year. His *Histoire de Louis XI.* was not so well received by the public, and was suppressed by the government in 1745, though in 1750 he became historiographer of France. A collection of moral essays, entitled *Considérations sur les mœurs de ce siècle*, is the chief basis of his reputation. He contributed largely to the *Mémoires* of the academy of inscriptions and belles-lettres, of which he became a member in 1739, and to the 4th edition of the dictionary of the French academy, to which he was admitted in 1747. His writings are disfigured by the characteristic indecency of his age, to which his dissolute life naturally disposed him. They have been collected and several times republished (10 vols. 8vo., Paris, 1806; 3 vols. 8vo., 1821).

DUCORNET, Louis César Joseph, a French artist, born in Lille, Jan. 10, 1806, died April 27, 1856. He was born without arms, but by patience and courage was enabled in childhood to obviate in a great measure the effects of this misfortune by making his feet perform all the ordinary offices of hands. His father hoped to turn this pedal dexterity to some advantage by educating him to become an engraver of music or a writing master. Young Ducornet, however, had conceived a taste for painting, and so much astonished Watteau, professor at the school of design in Lille, by the drawings which he executed with his feet, that at the age of 13 he was received into the school as a pupil. Three years later he obtained the first prize for a drawing of the human figure from nature, on which occasion his native city settled upon him a pension of 300 francs, which was subsequently increased by the government to 1,500. Enabled by this means to pursue his studies in Paris, he produced in 1828 his "Parting of Hector and Andromache," which he presented to the city of Lille. After the revolution of 1830 his pension was withheld. During the remainder of his career he painted numerous pictures of history and *genre*, and portraits, which have obtained considerable popularity, less on account of their merits, perhaps, which are considerable, than of the extraordinary circumstances under which they were executed. One of his latest works, "Edith finding the Body of Harold" (exhibited in 1855), was painted for Napoleon III. Ducornet was not only destitute of arms, but there were certain malformations in his lower limbs which seemed to present insurmountable obstacles to the acquisition of proficiency in his art. He nevertheless used his brushes with remarkable dexterity, passing them from one foot to the other with rapidity, and making the most delicate strokes with perfect ease and accuracy. He had but 4 toes on each foot, but the wide space thereby left between the great toe and the next one, by enabling him to grasp his brushes and maul stick firmly, rather facilitated the operation of painting. He was of a vivacious temperament, and in an animated conversation was in the habit of gesticulating with his legs as an ordinary person would with his arms. His father was his inseparable companion, frequently carrying him on his shoulders that his feet might not become incapacitated for painting.

DUCTILITY (Lat. *ductilis*, from *duco*, to draw), the property of bodies in virtue of which they may be drawn out in length without fracture. Malleability is a similar property, and

both are sometimes found in the highest degree in the same substance; thus, gold may be drawn out into the finest wire or beaten into the thinnest leaf. Iron from its fibrous texture admits of being drawn into delicate wire of great strength, but it appears deficient in the laminated structure by which it may be hammered into fine leaves. The arrangement of bodies according to their ductility is nearly the same as that according to their malleability. Gold is the most ductile of all substances; others succeed it thus: silver, platinum, iron, copper, zinc, tin, lead, nickel, palladium, cadmium. Though this property is possessed in the highest degree by most of the metals, it is also shared by other bodies, as by glass when softened by a red heat. In this condition, by merely inserting a hooked wire into the soft mass, a thread is drawn out of more uniform size than could be obtained by this simple method from the most ductile metal. Attaching the thread to the circumference of a revolving cylinder, the glass is coiled around it in a fibre nearly as fine and flexible as that of the silkworm. The highly elastic gums possess a certain degree of ductility, and wax acquires the same property when it is softened by heat. Other bodies become ductile when mixed with some fluid to make a paste, as clay or flour with water, whiting mixed with oil to make putty, &c. As seen in glass and wax, a change of temperature affects the ductility of some bodies. Some are rendered more ductile by increasing their temperature nearly to the fusing point; gold, silver, lead, &c., are not thus affected; brass and the variety of bar iron know as red-short are less ductile when heated than at the ordinary temperature. It is on the property of ductility that the preparation of metallic wires depends. These are drawn through successive holes in a steel plate, each hole of less diameter than the preceding; and for very fine wires a coating of another metal serves to protect the inner wire, which is afterward isolated by dissolving the outer metal in some solvent which does not affect the other. Platinum thus protected by silver was drawn out by Dr. Wollaston in wire only $\frac{1}{300}$ of an inch in thickness.

DUDDON, a river of England, celebrated by Wordsworth in a series of sonnets. It rises near the stones which mark the junction of the counties of Cumberland, Lancashire, and Westmoreland, flows 20 m. in a S. direction, and discharges its waters into the Irish channel by a broad estuary, forming at low tide an immense surface of sand flats nearly dry.

DU DEFFAND, Madame. See Deffand.

DUDEVANT, Amantine Lucile Aurore Dupin, a French novelist, celebrated under the assumed name of George Sand, born in Paris, July 5, 1804. Her father, Maurice Dupin, died when she was scarcely 4 years old, leaving her to the care of her grandmother, the countess de Horn, who was the illegitimate daughter of Marshal Saxe, the natural son of Augustus II., king of Poland, and of the celebrated countess Aurora de Königsmark. She received her first education at the family country seat of Nohant, near La Châtre, where she led a somewhat eccentric life. She subsequently spent nearly 2 years at an aristocratic boarding school in Paris known as *le couvent des Anglaises*, where she became a devout Catholic, and at one time entertained a design of taking the veil. In 1820 she returned to Nohant, and on the death of her grandmother a few months later, lived with some friends in the vicinity of Melun. Here she became acquainted with a young man of 26, Casimir Dudevant, to whom she was married in Sept. 1822. The young couple took up their abode at Nohant, but after a few months of comparative bliss came to the conclusion that their tempers, habits, and tastes could not harmonize. Disagreement increased yearly through trifling causes, and the estrangement was embittered by pecuniary embarrassments. Finally in 1831 Mme. Dudevant, desirous of trying her fortune as a writer, obtained permission of her husband to pass 3 months out of every 6 in Paris. She consequently repaired to the metropolis, and through her countryman Jules Sandeau, whom she had previously known at La Châtre, was introduced to Henri Delatouche, then editor of the *Figaro*. She contributed a few articles to that paper, but not possessing the extemporaneous facility requisite for a journalist, she found herself entirely dependent upon the meagre allowance of 1,500 francs paid by her husband. In order to reduce her expenses, and to visit unnoticed the public galleries, libraries, and theatres, she assumed the dress of a male student. Meanwhile she wrote a novel in conjunction with her friend Jules Sandeau, who succeeded in finding a publisher. This first performance, entitled *Rose et Blanche*, and bearing the name of Jules Sand, was received favorably enough to encourage the publisher to take another novel from the same hands. Sandeau had nothing ready, but his associate had just completed during a stay at Nohant a book which appeared in May, 1832. This was *Indiana*, which had a brilliant success. Jules Sandeau, modestly declining any share in a work which was, in part at least, ascribed to him, resumed his full name; and by Delatouche's advice the lady kept the shortened appellation of Sand, with the prefix George. About the same time it was rumored that the successful author was a woman, and this added to the interest created by *Indiana*. This was soon followed by *Valentine*, a scarcely less striking and more perfect production, which was also eagerly received. "George Sand" became then a favorite novel writer for the *Revue des deux mondes*. In 1833 she produced *Lélia*, the boldest if not the greatest of her efforts, which caused a profound sensation by the principles of infidelity and social disorder which it seemed to advocate. From this time the author was looked on with dread and suspicion by many of her former admirers. To recruit her health, she now started for Italy in company with Alfred de Musset, the poet; but they separated in

Venice, he returning to France after a severe illness, and she remaining to write her *Jacques*, *André*, and *Les lettres d'un voyageur*. On her return to France in the beginning of 1835, she met Michel de Bourges, the eloquent lawyer, who drew her into politics, Lamennais, with whom she debated the highest questions of religion, and Pierre Leroux, who was her initiator into the doctrines of socialism. Their influence was perceptible in several of her subsequent works, such as *Simon*, *Spiridion*, and *Consuelo*. The difficulties with her husband had so increased that a separation was desirable for both; and through the management of Michel, who had become her counsel, she obtained a decree by which she was separated from her husband, and restored to the management of her own fortune and the guardianship of her children. Her life now became comparatively settled; she made Nohant a resort for her friends, and attended to her children's education, without neglecting her literary labors. In 1838, for the benefit of her son's health, she spent a winter in Majorca, where she was accompanied by the pianist Chopin. In 1845 she turned her pen to new and more congenial subjects, and began to write pastoral novels unparalleled for charm, simplicity, and artlessness; among these are *François le Champi* (first produced as a play in 1849), *La petite Fadette*, and *La mare au diable*. The revolution of Feb. 1848, brought her again into the political arena, and she is said to have upheld with her pen many of the measures of Ledru-Rollin, then a member of the provisional government; but a few months afterward she returned to her favorite country seat and her wonted occupation. In 1854 she published in the *Presse* newspaper an interesting autobiography, entitled *Histoire de ma vie*, which does not go beyond the year 1845. *La filleule* deserves a special notice among her recent productions; the latest of which are *La Daniela*, *L'homme de neige*, and *Elle et lui*, in the *Revue des deux mondes*. She has also written several plays, of which *François le Champi* has been the most successful; her last effort in this line was an adaptation of Shakespeare's "Midsummer Night's Dream," performed in Paris in 1857. Many of George Sand's works have been translated and published in the United States, *Consuelo* and *Teverino* among the number. Among the distinguished names in modern French literature, for beauty and vigor of style she is without a peer.

DUDLEY, a town, parish, and parliamentary borough of Worcestershire, England, but locally comprised in the co. of Stafford, which entirely surrounds it; pop. in 1851, 37,962. The town stands on a hill about 8 m. from Birmingham, and contains 4 churches and a number of chapels of various denominations. The charitable foundations, such as free schools, infirmaries, and industrial schools, are numerous. In addition to these there are a grammar school founded in the reign of Elizabeth, many literary and scientific societies, and a museum of natural curiosities. The neighborhood furnishes almost inexhaustible supplies of iron, which is here manufactured and transported by canal to all parts of the kingdom. Coal is obtained in like abundance. At a place called Queen's Cross there is a coal mine in a state of ignition, the smoke and gas from which issue from the crevices in the rocks. Such phenomena are by no means uncommon in Dudley; subterranean fires of this description have broken out here at times for upward of a century. The limestone quarries of the neighborhood are remarkable. The stone is usually excavated from the solid rock, leaving vast caverns, the roofs of which are supported by limestone pillars. One of these caverns is 2 m. long, and traversed by a canal by which the quarried material is conveyed away. In the 8th century Dudo or Dodo, a mythical Saxon prince, is said to have built on an eminence near here a strong castle, the ruins of which still remain. It is of oblong shape, and has a tower at each end. In 1644 it was garrisoned by a body of royalists under Col. Beaumont, and held out for 3 weeks against the parliamentary forces. Dudley sends one member to the house of commons.

DUDLEY, the name of an English historical family, descended from John de Somerie, who acquired the castle and lordship of Dudley in the reign of Henry II. The barony passed by marriage from the house of Somerie to that of Sutton in the reign of Edward II. John Sutton (Lord Dudley, died in 1487) was distinguished as a soldier in the wars of the roses, and left 2 sons, Edward and John. A grandson of the latter was Edmund Dudley, the extortionary minister of Henry VII., who was executed for high treason under Henry VIII. (Aug. 18, 1510). His son John Dudley (1502–1553) was created Viscount L'Isle by Henry VIII. (1542), earl of Warwick by Edward VI. (1547), and after effecting the ruin of the duke of Somerset was made duke of Northumberland (1551). He persuaded the young king Edward to set aside his sisters Mary and Elizabeth from the succession, and bequeath the crown to Lady Jane Grey, who belonged to a branch of the royal family, and had married Lord Guilford Dudley, a son of Northumberland. The attempt proved a failure, and Northumberland perished with his son and daughter-in-law on the scaffold. His son Ambrose (1530–1589), usually called the good earl of Warwick, to which dignity he was restored by Elizabeth (1561), served in youth in the Netherlands, and was afterward a distinguished ornament of the English court. He died childless.—Robert, younger brother of the preceding, earl of Leicester, the favorite of Queen Elizabeth, born about 1531, died in Cornbury, Oxfordshire, Sept. 4, 1588. He came early into the service of Edward VI., by whom he was knighted. In 1550 he married Amy, the daughter and heiress of Sir John Robsart, the nuptials being solemnized in presence of the young king. In the first year of Mary he was imprisoned and condemned with his father for the attempt to transfer the succession to

Lady Jane Grey, but the sentence of death was soon remitted, and he was afterward restored in blood. On the accession of Elizabeth he met with rapid preferment, his elegant and courtly address winning for him the chief place in the personal esteem of the queen. He was made master of the horse, knight of the garter, and privy councillor, and was enabled to maintain the splendor of his station by grants of manors and castles. The queen was delighted with his society, and their intimacy was the occasion of scandal, and of a belief that he was encouraged to aspire to the hand of his sovereign. In 1560 his countess died, not without suspicion of violence, in the lonely mansion of Cumnor, in Berkshire, where she was living in retirement; and when, soon after, the English queen proposed the marriage of Dudley with Mary of Scotland, the latter declined the offer, on the ground that Dudley was the chosen spouse of Elizabeth, who wished only to exalt his dignity by giving him an opportunity to reject the hand of some other princess. In 1564 he was created baron of Denbigh and earl of Leicester, and was elected chancellor of the university of Oxford, as he had formerly been high steward of that of Cambridge, and his favor at court caused other important offices throughout the kingdom to be conferred upon him. He soon after engaged in an intrigue with Lady Douglas Howard, widow of Lord Sheffield, who bore him a son, and claimed to have been privately married to him. In 1575 he was at the height of his power, and had the honor of entertaining the queen for 17 days at his castle of Kenilworth, in Warwickshire, on the decoration of which he is said by Dugdale to have expended £60,000, and the pageants and festivities on the occasion were hardly surpassed in magnificence even in that splendid reign. At what time he abandoned Lady Sheffield for the countess of Essex is uncertain, but in 1576 he secretly married the latter, immediately after she had become a widow. This marriage was at length revealed to Elizabeth, who was so enraged that she was with difficulty dissuaded from committing him to the tower, and she never forgave the woman who had gained his love. Even the young earl of Essex, in the height of his influence, pleaded for his mother in vain. A virulent and skilfully written book against him, entitled "Leicester's Commonwealth," was published in 1584, and was many times reprinted under different titles. The queen at length pronounced the anonymous author of it an "incarnate devil," and commanded her council to contradict it on her own personal knowledge and authority. In 1585 he commanded the English forces in the Netherlands, and received from the United Provinces the office of captain-general, and the whole control of their army and finances. This triumph of his ambition offended Elizabeth, and his ill success in the field against Alexander Farnese disappointed the Hollanders. In 1586 he was called back to England to give his advice in the case of the queen of the Scots, and recommended that she should be secretly despatched by poison; and in 1587 he returned to Holland, where his administration was so unpopular that he was soon recalled. In 1588, when the Spanish armada menaced the kingdom, he received an almost unprecedented share of the royal authority, being nominated to the new office of lord lieutenant of England and Ireland; and he commanded the forces at Tilbury for the defence of the capital, which were reviewed by the queen. He set out thence for his castle of Kenilworth, but was attacked with a violent malady, and died on the way. Notwithstanding his dissolute life, he affected in his letters a religious style, frequented sermons, observed fasts, and gave lands for charitable endowments. He erected the hospital at Warwick, and gave its mastership to a Puritan divine. The first marriage of Leicester is the theme of Sir Walter Scott's novel of "Kenilworth."—Sir Robert, son of the preceding by Lady Sheffield, born in Sheen, Surrey, in 1573, died near Florence in 1639. He fitted out a maritime expedition at his own expense, with which he sailed to America in 1594, and captured some Spanish vessels. In 1596 he distinguished himself at the taking of Cadiz. On his return to England he attempted to establish his legitimacy and secure his paternal estates, but was defeated in his efforts by his father's widow, the countess of Essex. He soon after, though a married man, seduced the daughter of Sir Robert Southwell, fled with her to Florence, and, assuming the title of earl of Warwick, was made chamberlain to the grand duchess of Tuscany, and duke of the holy Roman empire. He now added to his former title that of duke of Northumberland. Meanwhile his estates in England were confiscated, and he was outlawed, but at the Tuscan court his honors increased. By draining a vast morass between Pisa and the sea he made Leghorn a large and beautiful town. He improved its harbor, caused the duke to declare it a free port, drew many English merchants to settle there, and having received for his services a liberal pension, built a noble palace in the capital, and beautified his country seat of Carbello, 3 miles from Florence. He patronized literature, and was himself the author of several works, the best known of which is his *Del arcano del mare*, a remarkable collection of tracts on commerce and navigation (Florence, 1630, 1646; there is a copy in the British museum dated 1661).—The castle of Dudley belonged to the family of Sutton till in 1697 it passed by marriage to that of Ward. John Ward (died in 1774) was created (1763) viscount of Dudley and Ward, and this viscounty continued till it became extinct at the death of John William Ward (1781–1833), who entered the house of commons in 1802, and became secretary of state under Canning, April 3, 1827. He was a friend of Lord Byron.

DUDLEY, the name of several royal officers of Massachusetts.—Thomas, governor of the province, born in Northampton, England, in 1576, died in Roxbury, Mass., July 31, 1652. In 1630

he came to Massachusetts with the commission of deputy governor, and he was afterward chosen governor in the years 1634, 1640, 1645, and 1650. He was a man of integrity and piety, though intolerant, like most of his generation.—Joseph, governor of the province, son of the preceding, born Sept. 23, 1647, died in Roxbury, April 2, 1720. He was graduated at Harvard college in 1665, served in the Indian war in 1675, was sent to England as agent for the province in 1682, appointed president of New England in 1686, superseded by Andros a few months later, and made chief justice. He went to England again in 1689, was chief justice of New York from 1690 to 1693, then 8 years lieutenant-governor of the isle of Wight, and finally governor of Massachusetts from 1702 to 1715. He was a man of high moral character, and a scholar.—Paul, son of the preceding, and chief justice of the province, born Sept. 3, 1675, died in Roxbury, Jan. 21, 1751. He was graduated at Harvard college in 1690, and afterward studied law in London. He returned to Massachusetts in 1702, with the commission of attorney-general. In 1718 he was appointed judge, and on the death of Lynde in 1745, became chief justice. By his will he bequeathed £100 to Harvard college, the interest of which was to be applied to the support of an annual lecture. This lecture is called from its founder the Dudleian lecture, and, according to the direction of the founder, is delivered on one of 4 subjects which are treated of in succession. The 1st of these is natural religion; the 2d, the Christian religion; the 3d, the errors of the Roman Catholic church; and the 4th, to explain, maintain, and prove the validity of the ordination of ministers according to the ancient custom in New England. He was a fellow of the royal society, and beside 12 treatises chiefly on natural history, in the "Transactions" of that association, published a work against the church of Rome.

DUDLEY, Benjamin Winslow, an American surgeon, born in Spottsylvania co., Va., in 1785. He received his education at Transylvania university, Lexington, Ky., and attended lectures at the medical school of the university of Pennsylvania in Philadelphia, where he took his medical degree in 1806. In 1810 he went to Europe for the further study of his profession, where he remained as the pupil of Sir Astley Cooper, the elder Cline, and Abernethy, in London, and Larrey, Dubois, and Boyer, in Paris, till 1814. On his return he established himself in Lexington, Ky., in July, 1814, and on the day of commencing practice, performed two difficult operations, that for strangulated hernia, and trephining in a case of fractured skull. The operation for stone in the bladder, always a formidable one, though of comparative frequency, has won him a high degree of reputation. He has operated for this disease 207 times and only lost 5 patients, and has had occasion to repeat the operation in but one instance. Recently he has applied a ligature to the carotid artery for aneurism within the skull with success, where trephining had been tried before by another surgeon for supposed water on the brain. For the last 5 years Dr. Dudley has withdrawn from active practice. He resides at Lexington, Ky., and has published several medical essays.

DUDLEY, Charles Edward, an American senator, born at Johnson Hall, Staffordshire, England, May 23, 1780, died in Jan. 1841. After the death of his father he came with his mother to Newport, R. I., in 1784. On reaching manhood he entered into trade in that town, and made at least one voyage to the East Indies as supercargo of a ship. He subsequently removed to New York, where in July, 1809, he was married to Blandina, daughter of Rutgers Bleecker, one of the most eminent of the Dutch families of that city. Two years later he removed to Albany. He was elected state senator for 3 successive terms in 1820–'25, mayor of the city in 1821 and 1828, and in 1829 U. S. senator to serve out the unexpired term of 4 years of Martin Van Buren, who had resigned to assume the duties of governor of the state of New York. Mr. Dudley was particularly fond of astronomical science, and had long cherished the hope that it would receive greater attention in this country. His wishes received their accomplishment in 1856, in the erection and endowment of the Dudley observatory at Albany, to which his widow has contributed the munificent sum of $70,000. This institution is supplied with the best instruments for astronomical purposes to be obtained in the United States or Europe, and with all the appliances necessary for rendering it a complete observatory.

DUDLEY, Sir Henry Bate, an English clergyman and author, born in Fenny Compton, Warwickshire, Aug. 25, 1745, died Feb. 1, 1824. Not finding the emoluments of his curacy sufficient for his convivial tastes, he turned his attention to literature, established several newspapers, among others the "Morning Post" and "Morning Herald," and also wrote some dramatic works. His original name was Henry Bate, but in accordance with the will of a relative who left him some property, he assumed in 1784 that of Dudley. He was made a baronet in 1812, and subsequently obtained a prebendal stall in the cathedral of Ely.

DUEL, a premeditated combat between two persons, with deadly weapons, for the purpose of deciding some special difference or quarrel. It is of very ancient origin, considered in a comprehensive sense, though what is now understood specifically by the term dates from the first half of the 16th century. The accounts of single combats that occurred in antiquity are numerous, and are to be found in both sacred and profane history, and in poetry. The celebrated single combat of T. Manlius Torquatus with a gigantic Gaul in the war of 361 B. C., and other instances, prove that the duel was not unknown to the Romans, though the story that Antony challenged Octavius to single combat may be an invention. The Greeks, too, were no strangers to it, and many a single com-

bat of mortals and gods is immortalized in the Iliad; and the fight between David and Goliath has often been mentioned to show that the Jews and other Asiatics were acquainted with the practice. The Arabs of Mohammed's time knew it, and it may be asserted that it has been recognized in almost every community. The barbarians who overran the Roman empire gave to duelling its modern character, which is believed to have had its origin in the wager of battle, or judicial combat, the object of which was to vindicate the innocent. To rude races, by whom courage was held in the highest honor, the belief was natural that success in combat was the test of truth. The trial by combat was legalized as early as A. D. 501; the practice extended, and was maintained for centuries after the modes of thought in which it originated had disappeared. It was recognized as legal in England as late as 1818 by the highest law court, and was abolished by parliament in 1819; but in France its judicial character was never formally admitted after 1547. It belonged to the list of ordeals, and the solemnities that attended its observance were calculated to impose upon men's minds, and to give it the force that proceeds from permanence. Jurists and churchmen upheld it, and monarchs were its patrons and regulators. This class of duels became so common that various attempts were made to lessen their number. By the truce of God, 1041, they could not be fought from Wednesday to Monday, the days intervening being sacred to Christ's passion. In 1167 an edict forbade duels upon claims that did not exceed 2½*d.*, a circumstance that shows their absurdity, for even allowing largely for the change in the value of money, the sum mentioned was less than a dollar. The occurrence of the crusades and the study of the civil law had some effect in abating personal combats.—France was the country in which the duel was most common, and in the reign of the chivalric Francis I. it assumed the character which it has ever since maintained. That king laid down the principle "that the lie was never to be put up with without satisfaction, but by a base-born fellow;" and lies were divided into 32 categories, each having its own particular mode of satisfaction. But it was the king's conduct that had the most influence on the minds of fighting men. The personal quarrel between him and the emperor Charles V. was one of the scandals of that age, and grew out of the determination of the former to break the promises which, as a prisoner, after the battle of Pavia, he had made to the latter, in order to obtain his freedom. The emperor accused the king of violating his pledge, and proposed to make his accusation good with his sword. Francis returned the lie in coarse terms, and offered to meet his rival in arms at any place he might name. Charles named the banks of the Bidassoa, the very spot where he had restored Francis to liberty. By quibbling, the king prevented the meeting he had appeared to desire. The violence of the disputants excited much attention, and from their high rank a most pernicious example was set to the hot spirits of the time. It became the custom to decide disputes with the sword, and from that period dates the modern duel "as far as it relates to mortal combat upon a mere point of honor." It was reported that Francis had offered to fight an eminent German who had offended him, but who had declined the proffered meeting. Duelling became the rage in France, and has so continued until now. The lapse of 3 centuries appears not to have changed the character of French duelling, and the combats in which some of Henry III.'s *mignons* distinguished themselves were in no respect worse than that in which a Paris editor was stabbed by an army officer in 1858. The party dissensions and civil wars of France that raged during the last 30 years of the rule of the house of Valois, and in the early part of the reign of the first Bourbon king, naturally tended to make duelling more common and more savage than it could have been under other circumstances. It was the age, too, of assassination, which shows that duelling does not necessarily imply the existence of the sentiment of honor. Henry IV. has been praised for the efforts which he made to prevent duelling, but his practice was in flagrant opposition to his edicts, and few sovereigns have done more to make single combats fashionable. It is asserted that in his reign 4,000 persons fell in such combats, and that he granted 14,000 pardons for duelling; yet among his edicts was one that made duelling a crime against royalty, punishable with death. He further required that persons who had quarrelled should submit their grievances to the governor of their province, to be laid before the marshals of France and the constable, thus seeking to carry out the idea which had originated with Charles IX., to establish the jurisdiction of the court of honor. Louis XIII. treated duellists as his father had, though justice was done in the case of the infamous Bouteville, one of the Montmorencys, and the worst duellist of his day, who, by the influence of Richelieu, was brought to the scaffold. Louis XIV. set his face against duelling, and the autocratic position to which he attained enabled him to lessen its frequency, though it had been increased by the wars of the Fronde, in the early part of his reign. Edict after edict was issued by him against it, and courts of honor were instituted for its prevention. The regency revived duelling, which Louis XV. sought to stop, but with little effect. John Law was a noted duellist, and the duke de Richelieu was another, while St. Evremont and St. Foix carried dueling to such perfection that they well nigh made it a farce. The reign that ushered in the revolution had its share of duels, a party to one of which was the count d'Artois, afterward Charles X., his antagonist being the duke de Bourbon-Condé, while two of the most famous swordsmen were the chevalier d'Eon and the chevalier de St. Georges. The duke de Lauzun, who served in the forces that were sent to aid the

United States, was a noted duellist. It is a curious circumstance that in the last duel of any moment fought under the old monarchy, the principal party was a man who has exposed admirably the absurdity of duelling, and who was imprisoned for fighting by the court of honor, which was presided over by Richelieu, then more than 90 years old. The first tendency of the revolution was to suppress duelling, both on partisan and patriotic grounds. It was looked upon as aristocratic, and the life of every man was said to belong to his country. When the reaction commenced duelling was revived, and all the more readily and universally because of the ascendency of the military. Napoleon was averse to duelling, but had to tolerate it, even while expressing his contempt for duellists. The story that Sir Sidney Smith challenged him at Acre, and that he answered he would fight a Marlborough, is an invention; but when Gustavus IV. of Sweden sent him a message, his answer was that he would order a fencing master to attend him as a plenipotentiary. The most celebrated duels in France since the revolution were between Gen. Gourgaud and Count Ségur, Col. Pépé and Lamartine, Bugeaud and Dulong, Armand Carrel and Émile de Girardin (in which the former lost his life), Thiers and Bixio, Proudhon the socialist and Félix Pyat. Since 1837 duellists and their seconds are liable to the criminal law in France for any homicide or manslaughter resulting from the duel, but in the conduct of the trial much discretionary power is left to the prosecuting magistrate. There have been female duels in France; a celebrated one was fought under the regency between Madame de Nesle and the countess de Polignac, for the possession of the duke de Richelieu. There was another female duel as late as 1827, and in 1828 one between a young girl and a soldier who had betrayed her, and between a French and a German woman, who were both in love with a painter.—Italy has not been much behind France in duelling, and it was the land of punctilio in those days when the duel was establishing itself in the latter country. The Italians excelled in the use of the lighter descriptions of weapons, and among the multitudes of them who swarmed over the world, adventurers of all kinds, not a few were teachers of the use of arms. Public opinion favored duelling, but it could not prevent assassination, which was as frequent as if the other art of killing had been unknown. The Italians are accused of conducting their duels treacherously, but the practices charged on them might easily be paralleled by facts taken from the history of French duellists. —Single combats were of ordinary occurrence in Spain during the long contest between the Christians and Mussulmans, and duelling was sometimes encouraged by laws which at other times were directed against it. In 1519 Charles V. issued an edict for its suppression; though, as we have seen, it was his conduct in his dispute with the French king that gave to the practice its power in modern times. Of late years individual combats have been rare in Spain, and it was probably his Irish blood that caused the Carlist O'Donnell to challenge the Christino Lopez—a challenge that was accepted, but led to no fight. Duelling is even less common in Portugal than it is in Spain.—Duels were favored by the northern races, and in Denmark women were not allowed champions as in other countries, but compelled to do their own fighting, though certain advantages were permitted them, which enabled them to assert their superiority. In Norway this species of combat was held in high honor, but in Sweden it was nominally forbidden under severe penalties. Gustavus Adolphus was especially opposed to duelling, and on one occasion prepared a gallows for that party who should survive a particular combat; yet he offered the "satisfaction of a gentleman" to an officer whom he had struck.—In Germany duelling is much less in vogue than in France, excepting among students in the universities. In Austria and Hanover the ancient laws on the subject, inflicting long and rigorous imprisonment upon those who kill or maim their antagonists, are still in force, and in the latter country the sentence of death may still be pronounced whenever homicide results from a predetermination of fighting for life or death. A law was passed in Saxony, Aug. 13, 1855, punishing such extreme cases of premeditated homicide with imprisonment, varying from 4 to 20 years; but in all other cases it is limited to a short time, not only in Saxony, but throughout Germany. Tribunals of honor for military men have existed in Prussia since July 20, 1843, for the purpose of reconciling the contending parties when it can be done without prejudice to the military code of honor. If reconciliation is impossible, the duel takes place; if no injury is done, the imprisonment never exceeds 6 months; and even if it prove fatal, never more than 4 years. The duel which created the greatest sensation in Berlin within the last few years was fought in 1856 between Hinckeldey, the president of police, and Rochow, a nobleman and an army officer, in which the former lost his life.—Russia has known little of the duel, the fantastical point of honor being there mostly incomprehensible. Russians when abroad, however, have shown a readiness to fight in single combat quite equal to their steadiness in the battle field. The Poles have proved themselves stanch duellists, and the judicial combat was frequent in old Poland. The Netherlands have closely imitated France, both in duelling and in abortive attempts to suppress it. A new law on duelling was passed in Belgium in 1841.—It has been asserted that single combats were introduced into England by the Normans. They are said to have instituted the wager of battle, from which duelling proceeded, and which it is believed was unknown to the Saxons. Yet Lappenberg states that "William the Conqueror speaks of the judicial combat as a known English custom." It was a favorite mode of procedure, and was not formally abolished until the last

year of the reign of George III.; and as late as 1774 it was defended by some of the greatest men of England. In the chivalrous times there were numerous personal combats in England, but they hardly come under the head of duelling; and duels may properly be said to have commenced in that kingdom about the same time that they did in France, so wide-spread was the effect of the evil example of Francis I. and Charles V. In the reign of James I. there were many duels between British subjects, one of the most noted of which was that fought between Lord Bruce and Sackville, afterward earl of Dorset, in which the former was killed. The cavaliers were a class of men with whom the point of honor was likely to be in as high favor as it was with Lord Herbert of Cherbury, whose fantastic notions had been increased by his residence in France, and whose sensibility on the subject of ladies' "topknots" is among the ludicrous moral features of the duello. Scott has, in "Woodstock" and in "Peveril of the Peak," exhibited their ideas on the subject. One of the sermons delivered by Chillingworth before Charles I. contains a warm expostulation against duelling. Cromwell was a foe to duelling. After the restoration it became still more common, from the spread of French ideas. Some of the English duels of that time were of a character in perfect keeping with its loose morality. The duke of Buckingham killed Lord Shrewsbury; Lady Shrewsbury, on whose account the duel was fought, attending the duke as a page, and then passing the night with her lover. In Anne's reign, the duel between the duke of Hamilton and Lord Mohun, in which both fell, caused much feeling, from its political character, and the atrocities that marked it. Duels became more numerous as society became more orderly, and many of the most distinguished Englishmen took part in them. William Pulteney, leader of the opposition, fought Lord Hervey. Wilkes was engaged in 2 duels. The Byron and Chaworth duel happened in 1765. Throughout the reign of George III. duels were frequent; among those who fought in England were Charles James Fox, Sheridan, Pitt, Canning, Castlereagh, the duke of York, the duke of Richmond, Sir F. Burdett, and Lord Camelford; the last named, a member of the Pitt family, was the great duellist of the time, and fell in a duel in 1804. In the present reign, as well as in those of George IV. and William IV., there have been some noted duels; the strangest of which was that between the duke of Wellington and Lord Winchelsea, in 1829, the duke challenging the earl because of the latter's hot reflections on his conduct at the time he determined upon emancipating the Roman Catholics. The duke fired at his antagonist, who fired in the air, and then apologized. Perhaps no duel of our time had less excuse, because the challenger's character for courage was so completely established. Mr. Roebuck, after admitting that there are circumstances under which duelling is necessary—an admission that shows the strength of the custom—says: "In the duke of Wellington's case, no such imputation could have been hazarded, and his forbearance under insult would have been esteemed by his country as a magnanimous disregard of vexatious annoyance, and would have been appreciated as a proof both that his temper was under the serene control of reason, and that he disdained to avail himself of this wretched means of exhaling his passion, or satisfying his revenge. The nation felt humiliated when they learned that their great hero had submitted to the folly of a duel." Wellington might have pleaded the example of Marlborough, who sought a duel with Lord Paulett, in 1712, which the latter took care to prevent. In 1835 Mr. B. Disraeli challenged Mr. Morgan O'Connell. Among the most conspicuous duels in England of late years was that fought between the earl of Cardigan and Capt. Tuckett in 1840.—Ireland is that part of the British empire in which duelling has always been most in vogue. In the latter part of the last century there was scarcely an Irishman of note who had not been "out," and many of them had fought often. Grattan, Curran, Lord Clare, Flood, Burrowes, Barrington, Toler, and many others, men of high positions, were among the Irish duellists of those times. In 1815 Daniel O'Connell fought with and killed Mr. D'Esterre, a member of the Dublin corporation, which the former had stigmatized as a "beggarly" body; and the death of his antagonist is said to have caused Mr. O'Connell great grief. He afterward became involved in a dispute with Mr. (subsequently Sir Robert) Peel, that would have led to a duel if he had not been arrested. Mr. Peel wished to fight the gentleman who was to have been Mr. O'Connell's second.—In Scotland duels have not been so common as in Ireland, yet the Scotch have always evinced something more than readiness to go to "the field of honor." In 1822 Mr. James Stuart, well known by his work on the United States, killed Sir Alexander Boswell, son of Johnson's biographer, in a duel, which grew out of gross newspaper attacks on the former. Mr. Stuart was tried and acquitted. Mr. Francis Jeffrey, who was of counsel for the defence, went almost the entire length of upholding duelling, and boldly assumed that the man who slew another under the circumstances that caused Mr. Stuart to slay Boswell was not guilty of murder in any sense. The court, while it charged that killing in a duel was murder, declared that there was no evidence of malice on the part of Mr. Stuart, and praised his conduct on the ground; and when the acquittal was given, the court congratulated him on the result. These incidents, and the stress which the court laid on the licentiousness of the press, through which Mr. Stuart had been assailed without provocation, show how strongly even the opinion of enlightened men has been pronounced in favor of duelling. It is a singular fact that Boswell, when a member of parliament, took the principal part in getting two old Scotch statutes repealed that were directed against duelling, one of which

made the mere fighting of a duel, though it should have no evil result, punishable with death. —Duelling has been known in the United States from the very beginning of their settlement, the first duel taking place in 1621, at Plymouth, between two serving men. Mr. Sabine thinks it possible that in the ludicrous punishment inflicted on these chivalrous combatants we can find the cause of the difference in opinion on duelling that exists between the North and the South. They were sentenced to be tied neck and heels together for 24 hours, but a portion of the punishment was remitted. Castle island, in Boston harbor, is said to have been a duelling ground for Englishmen. In 1728, a young man named Woodbridge was killed in a duel on Boston common, by another young man named Phillips. They fought without seconds, in the night time, and with swords. Aided by some of his friends, Phillips got on board a man of war and escaped to France, where he died a year afterward. A great sensation was caused, and a new and severe law against duelling was enacted. There were few duels in the revolution, the most noted being those between Gen. C. Lee and Col. John Laurens, in which the former was wounded, and between Gens. Cadwallader and Conway, in 1778, in which the latter received a shot in the head from which he recovered. Button Gwinnett, one of the signers of the declaration of independence, from Georgia, was killed in a duel with Gen. McIntosh, in May, 1777. In 1785 Capt. Gunn challenged Gen. Greene twice, both being citizens of Georgia, and threatened a personal assault when the latter refused to meet him. Greene wrote to Washington, acknowledging that if he thought his honor or reputation would suffer from his refusal he would accept the challenge. He was especially concerned as to the effect of his conduct on the minds of military men, and admitted his regard for the opinion of the world. Washington approved of his course in the most decisive terms, not on moral grounds, but because a commanding officer is not amenable to private calls for the discharge of his public duty. Gen. Hamilton was killed in a duel with Col. Burr in 1804, the latter being vice-president, and the former the greatest leader of the opposition. This duel is always allowed the first place in the history of American private combats. That which stands next is the duel between Capts. Barron and Decatur, the latter being killed, and Barron severely wounded. Henry Clay and John Randolph fought in 1826, and Col. Benton, in closing his account of the fight, says: "Certainly duelling is bad, and has been put down, but not quite so bad as its substitute—revolvers, bowie knives, blackguarding, and street assassinations under the pretext of self-defence." Gen. Jackson killed M. Dickinson in a duel, and was engaged in other "affairs." Col. Benton killed a Mr. Lucas, and had other duels. In 1841 Mr. Clay was on the eve of fighting with Col. King, then a senator from Alabama, and elected vice-president in 1852. Mr. Cilley of Maine fought with Mr. Graves of Kentucky in 1838, near Washington, and the former was killed. This duel caused nearly as much excitement as that between Hamilton and Burr. Both parties were members of congress. Duels have been numerous in California since that country became a part of the United States, and some of them have been of a very severe character. Formerly they were very common in the U. S. navy, and valuable lives were lost. It is related of Richard Somers, who perished in the Intrepid, and who is said to have been a mild man, that he fought three duels in one day. Capt. Bolton (then Finch) shot Lieut. White, on an island in Boston harbor, in 1819; but White forced the duel on him, and fell. In 1830 President Jackson caused the names of 4 officers to be struck from the navy roll because they had been engaged in a duel. These encounters have not been so common in the navy of late years as formerly. The army has furnished duellists, some of them of the highest rank in the service. In the northern states, the force of opinion is strong against duelling; yet, at the beginning of the century, duelling was there common, and several duels were fought in New England, while the "code of honor" was in full force in New York and New Jersey. Five shots were exchanged between De Witt Clinton and John Swartwout, in 1802; and a challenge passed between Mr. Clinton and Gen. Dayton of New Jersey, in 1803.—Duels have been not unfrequent in the different parts of British America, and in Canada and the other provinces the state of opinion resembles rather that which prevails in our southern states than the opinion of neighboring New England.—By the common law, when one of the parties to a duel is killed, the survivor and the seconds are guilty of murder; and the participation in a duel where there is no fatal result, either as principal or second, is regarded as a misdemeanor. Many of the states of the American Union have, however, modified this rule by legislative enactment, and while in some of them the killing of a man is punishable with death, in others a term of imprisonment with forfeiture of political rights is substituted. Some states require certain officers of state to make oath either that they have not within a certain time been, or will not be, concerned in a duel; and in nearly all, the duellist and his abettors are disqualified from holding office or exercising the elective franchise for life, or for a term of years, according to the issue of the duel. In the American naval and military service, an officer implicated in a duel with a brother officer, either as principal or second, is liable to be cashiered, upon conviction by a court martial; and an equally stringent provision exists in the articles of war regulating the British military service. All the legislation that has been directed against it in the United States—and it is much—has been fruitless; and the labors of individuals of the highest character have been equally barren, in more than half the Union.—See J. G. Millingen, "The History of Duelling" (2 vols. London,

1841); Lorenzo Sabine, "Notes on Duels and Duelling, with a preliminary Historical Essay" (12mo., Boston, 1855).

DUER, John, an American jurist, born in Albany, N. Y., Oct. 7, 1782, died on Staten island, Aug. 8, 1858. He was the son of Col. William Duer of the revolutionary army, and on his mother's side a grandson of Gen. William Alexander, the claimant of the Scottish earldom of Stirling. In his 16th year he entered the U. S. army, but after two years left the service to pursue the study of the law and of general literature. He commenced the practice of his profession in Orange co., N. Y., whence about 1820 he removed to the city of New York, where he resided until his death. In 1825 he was appointed one of the commissioners to revise the statute law of the state, and afforded valuable assistance in the preparation of the first half of the work, his professional labors preventing him from giving more than occasional advice to his colleagues on the remainder. In 1849, after an honorable career at the bar, he was elected a justice of the superior court of New York city, a position which he filled until his decease. After the death of Chief Justice Oakley in May, 1857, he became the presiding justice of the court. He was a delegate to the convention which amended the state constitution in 1821, but seldom took an active part in public affairs. In 1845 he published a "Lecture on the Law of Representations in Marine Insurance," and in 1845–'6 a treatise on the "Law and Practice of Marine Insurance" (2 vols. 8vo.), which has become a standard authority in the United States. In 1848 he delivered a discourse on the life, character, and public services of Chancellor Kent, which was published, and at the time of his death was engaged in editing "Duer's Reports" of the decisions of the superior court. The 6th volume, which he did not live to complete, was revised by him while confined to his bed by a severe fracture of the thigh. Justice Duer was held in great esteem for his eminent judicial abilities, as well as for the dignity and impartiality with which he discharged the duties of his office.—William Alexander, brother of the preceding, a distinguished jurist, born in Rhinebeck, Dutchess co., N. Y., Sept. 8, 1780, died in New York, May 31, 1858. After serving for a short time in 1798 as a midshipman in the navy, he commenced the study of law, was admitted to the bar in 1802, and having practised for a few years in New York, removed to New Orleans to form a professional partnership with Edward Livingston. Compelled by his health to return to the north, he opened an office in his native village, and between 1814 and 1820 was a member of the state assembly, taking a prominent part in the debates on the establishment of canals and other important questions. In 1822 he was appointed judge of the supreme court in the 3d circuit, an office which he held until the close of 1829, when he was elected president of Columbia college. He discharged his academical duties with great benefit to the institution until 1842, when he retired on account of ill health, and took up his residence in Morristown, N. J. He is the author of a treatise on the "Constitutional Jurisprudence of the United States," of which an enlarged edition appeared in Boston in 1856; of a memoir of his maternal grandfather, Gen. William Alexander; and of various occasional addresses before historical and literary societies. In the early part of his life he was a frequent contributor of literary articles to the periodical press of New York.

DUFAU, Pierre Armand, a French publicist, and director of the imperial institution for the blind at Paris, born in Bordeaux, Feb. 15, 1795. His first important literary undertaking was a continuation of Velly, Villaret's, and Garnier's general history of France. In 1824 he published a collection of the fundamental laws of the nations of Europe and America, with notes upon the history of liberty and of political institutions in modern times. About the same date appeared his work on the "Partition of European Turkey between Russia, Austria, England, and the Greeks, with the Mediation of France." From 1830 to 1840 he was one of the most active writers of the moderate liberal party. He assisted in editing the *Temps* and the *Constitutionnel*, and was for a time chief editor of the latter journal. He was a teacher in the royal institution for the blind from 1815 to 1840, and its director from 1840 until within a recent period, when he retired with the title of honorary director. He took part also in founding and supporting other charitable institutions, and fulfilled several public functions until obliged to devote himself exclusively to the interests of the establishment confided to him. He continued, however, to write treatises upon political sciences, and for the amelioration of the condition of the blind, and was at the same time a contributor to some of the leading French cyclopædias. Many of his later works were crowned by the academy of sciences, and one of his earlier essays on the abolition of slavery in the French colonies (1830) by the society of Christian morality. He has also published, under the name of Armand, several light theatrical pieces. His latest works are: *Statistique comparée des aveugles et des sourds-muets* (4to., 1854), and *De la réforme du mont de piété*, a memoir presented to the academy of moral science in 1855.

DUFAURE, Jules Armand Stanislas, a French statesman and lawyer, born Dec. 4, 1798, was councillor of state in 1836, minister of public works in 1839, a member of the chamber of deputies from 1834 to 1848, and a champion of constitutional liberty until 1844, when he became the leader of a new moderate party midway between the opponents and supporters of the government. Although opposed to the agitation which caused the downfall of Louis Philippe, he adhered to the new republic in 1848, was elected to the constituent and legislative assemblies, and officiated as minister

of the interior from June 2 to Oct. 31, 1849. He was arrested on Dec. 2, 1851, but released on the following day. He has since devoted himself exclusively to the practice of the law, and holds a distinguished position at the bar of Paris. In 1858 he was one of the council for the defence in the trial of Montalembert.

DU FAY, Charles François de Cisternay, a French savant, born in Paris, Sept. 14, 1698, died July 16, 1739. In 1733 he was elected to the academy of sciences, and he was the only member of that body who has ever read papers in each of its 6 different departments that were deemed worthy of publication. He made new researches concerning phosphorus, the barometer, the refracting power of crystals, the magnet, and electricity. He introduced the theory of two kinds of electricity, the vitreous and the resinous. Among the chief services which he rendered to science were those which he performed as director of the *jardin des plantes*. Du Fay spent 10 years in rearranging and improving it, and made it the first establishment of the kind in Europe. At his request Buffon, who was as yet only known by his papers read to the academy, was appointed to succeed him in its superintendence.

DUFF, Alexander, D.D., LL.D., a Scottish missionary, born in the parish of Kirkmichael, in the co. of Perth, Scotland, in 1806. At a very early age his mind was directed to the ministry in the established church of Scotland; and with the view of preparing himself for its duties, he entered the university of St. Andrew's at the age of 15, and was graduated in due course. While a student he became intimate with Dr. Chalmers, who exercised a profound influence on his character and the direction of his career. He studied theology in St. Mary's college in the same university, and in the summer of 1829 was duly licensed to preach. During the later years of his academical studies he was the associate and bosom friend of a little circle, all of whose members became well known in the missionary field, among whom were the late John Adams and the late John Urquhart. These young men, while studying for the ministry, spent much of their leisure time in visiting the poor, distributing tracts, holding prayer meetings, and organizing and superintending Sabbath schools in destitute parts of the surrounding country. By none of the churches in Scotland had any effort yet been made to spread the gospel among the heathen. A more earnest spirit had indeed been gaining ground in the established church, and under the auspices of Dr. Inglis, aided by Chalmers and Thomson, and others of the evangelical party, a mission to India was resolved upon. Mr. Duff was selected as their first missionary, and having been ordained to the office of the ministry, he set sail toward the close of 1829. During his voyage to India he was twice shipwrecked, first on a reef while rounding the cape of Good Hope, and again on the coast of Ceylon, and narrowly escaped a third shipwreck when near the mouths of the Ganges. By the first of these mishaps he and his wife lost every thing that belonged to them. His plans of operation, his valuable library, and the fruits of his careful and laborious study, were all lost. His pocket Bible, which was picked up by a sailor among the rocks a day or two after the wreck, was alone saved. Arrived in India, a stranger among strangers, he was yet received and welcomed by many of his countrymen; but these, for the most part, were disinclined to further the special object of the Christian adventurer. They did not oppose him, but neither had they the heart to succor him. The well-known Rammohun Roy, however, who from his position and character could exercise considerable influence over the natives, entered warmly into the views of Duff, and with his assistance a school was commenced under a banian tree. Five young men assembled to receive instruction from the Scottish missionary. The shade of the banian tree was soon too narrow to protect the scholars from the fervor of the Indian sun, and it became indispensable to provide suitable accommodations for the protection and advancement alike of teachers and taught. From the very outset it was the purpose of Mr. Duff to lead his pupils through the entire range of British literature and science, and with all this the work of the missionary was never for a day lost sight of. The readings in classical literature and the scientific and philosophical lectures were all conducted with a definite end in view—the enfranchisement of the native mind, and the diffusion of the truth in philosophy and science, accompanied with the daily reading and critical and experimental exposition of the Scriptures. Mr. Duff's labors very soon began to tell, and the worth of the man, from the beginning, was apparent both to the native population and their British rulers. His honesty, perseverance, and zeal, in connection with his varied gifts and talents, soon gave a commanding influence to him and the Scottish college which he had established. In 1843 a crisis occurred in the history of the institution. It grew out of the disruption in the church of Scotland. On May 18, 1843, nearly 500 ministers of that church surrendered their livings into the hands of the state, rather than submit in the exercise of their official duties to the interpretation of the law relating to induction to benefices as given by the supreme judicatory, and confirmed by parliament. This they did on the ground that that interpretation was contrary to the law of Christ as laid down in the Scriptures. The aggregate value of the livings vacated was $10,000,000. When intelligence of this disruption reached Calcutta, Dr. Duff, and the brethren who had at intervals come to his help, had to consider the question whether they could retain their connection with the Scottish church, now, by the interpretation given to the law regarding benefices, thoroughly Erastianized, or whether they ought to throw in their lot with the seceding party, organized under the name of the Free Protesting church of Scot-

land. There was much to induce them to remain as they had been—the labors of 12 years, the complete organization of their edifices and plans, past success, the prestige of connection with a wealthy and endowed church, the sympathies of the government, and then, on the other hand, their ignorance as to the extent and ability of the Free church to aid them in the erection of new buildings, and in the carrying out of their well tried system. However, guided by a clear conviction of duty, Dr. Duff and his brethren at once and unanimously declared their adherence to the Free church, and vacated their honored and beloved institution, with all its valuable library and apparatus; and we believe they have had no cause to regret the step. On the death of Dr. Thomas Chalmers in 1846, the office of principal and professor of theology in the Free church college in Scotland was offered to him, but was refused. He returned to Europe in 1851 to recruit his broken health; but instead of finding there the necessary repose, he entered on the revival of the missionary spirit among the British people, and for that purpose visited the churches even in the remotest British isles. In 1854 he made a voyage to America, and during the months of February, March, April, and May, he visited the principal cities in the northern and western states, and passed through Canada. While he was in New York the various evangelical churches met by representation, and gave him a fraternal welcome, and the university of New York conferred on him the honorary degree of LL.D. In 1855 he returned to India, where he still remains, devoted with untiring industry to his missionary labors.

DUFFY, Charles Gavan, an Irish journalist and politician, born in Ulster in 1816. He embraced the profession of journalism at an early age, and for several years edited an influential newspaper at Belfast. At the same time he pursued the study of the law, and was subsequently called to the bar, but he has never practised. In 1841 he went to Dublin, where in 1842 he established the "Nation," a publication strongly in the interest of O'Connell and the advocates of repeal of the union; and in 1844 he was compromised in the proceedings instituted against O'Connell and the prominent repealers. In 1847 he joined the party of young Ireland, and in the succeeding year was tried with Smith O'Brien, Thomas Francis Meagher, and others, for sedition, but was acquitted. He then resumed the direction of the "Nation," in which he advocated various social reforms for Ireland, and between 1852 and 1856 represented New Ross in parliament. He has since emigrated to Australia, where he has been a member of the colonial legislature, and also of the ministry. He is the author of "Ballad Poetry of Ireland," and other publications.

DUFOUR, Guillaume Henri, a Swiss general, born in Constance in 1787. He was educated in Geneva, and after the annexation of that city to France in 1807, studied at the polytechnic school in Paris. Having entered the French army, he obtained a commission in 1809, served in the last campaigns of Napoleon, and distinguished himself during the Hundred Days. When Geneva was restored to Switzerland, he became a citizen of the republic; was continued in the rank of captain, which he had received under the empire, and in 1827 was promoted to that of colonel. In 1831 he was made chief of the staff of a corps destined to defend the neutrality of the republic. Intrusted with the management of the military school at Thun, with the survey of Switzerland, and, as quartermaster-general, with the reorganization of the federal army, he performed his duties with zeal and ability. When the organization of the Sonderbund, and the apprehended intervention of foreign powers, seemed to threaten the existence of the confederation in 1847, Dufour, at the age of 60, was chosen by the diet commander-in-chief of the federal forces, and not only rapidly suppressed the civil war, but also raised the reputation of his country in the eyes of Europe. His moderation on that occasion equalled his military ability. Being a conservative in politics, the events of 1848 lost him some part of his popularity; but he has since rendered important services to his country as a negotiator with foreign powers, especially in the question of the relations of Ticino and Neufchâtel with Austria and Prussia. Shortly before the termination of the Neufchâtel affair, he was again appointed commander-in-chief of the federal army in consequence of the warlike preparations of Prussia. He is the author of several works in French, the most important of which are: *De la fortification permanente* (1824; 2d edition, 1850); *Géometrie perspective*, &c. (1827); *Mémoires sur l'artillerie des anciens et sur celle du moyen âge* (1840); *Manuel de tactique* (1842).

DUFRÉNOY, Pierre Armand, a French geologist and mineralogist, born in Sévran, Seine-et-Oise, in 1792, died in Paris, March 20, 1857. His mother (born in 1765, died in 1825) was a poetess of some distinction. He entered the polytechnic school in 1811, and the school of mines in 1813. His first essay appeared in 1819, and was followed by a great variety of papers on mineralogy and geology, which gained for him a high reputation in the scientific world. His explorations in southern France and in the Pyrénées led him to develop the theory of metamorphism, according to which the production of many of the newer rocks is explained by the action of heat upon those of older date. He explored the vicinity of Naples, and in his work on the subject (*Des terrains volcaniques des environs de Naples*) he maintains that Herculaneum and Pompeii were destroyed by a landslide from Vesuvius, and not by lava ejected from the crater. In concert with Élie de Beaumont he explored between 1823 and 1836 various parts of France, England, and northern Spain, and the remarkable geological map of France which appeared in 1841 was the result of their labors. He was intrusted with a mission to England for the

purpose of investigating the effect of the substitution of the hot for the cold blast in furnaces employed for melting iron. He also investigated the methods of various metallurgical operations in Great Britain, and published in conjunction with Élie de Beaumont, Coste, and Perdonnet, an elaborate and valuable report entitled *Voyage métallurgique en Angleterre* (2d ed. 1837–'39, 2 vols. 8vo.). He was one of the most active members of the academy of miners, director of the *école des mines*, and professor of mineralogy and geology. He introduced a new classification of minerals based upon crystallography, and promoted in various other ways the study of mineralogy and meteorology. The 4th and last volume of the 2d and enlarged edition of his *Traité de minéralogie* appeared in Paris in 1859, with an additional volume of illustrations.

DU FRESNE, Charles. See Du Cange.

DU FRESNOY, Charles Alphonse, a French painter and poet, born in Paris in 1611, died at Villiers-le-Bel, near Paris, in 1665. His pictures are correct, but not otherwise remarkable, and he is now chiefly remembered as the author of a Latin poem entitled *De Arte Graphica*, the "Art of Painting," which has been 3 times translated into English, viz.: into prose by Dryden (4to. London, 1695), by Wills (4to. 1754); and into verse by William Mason, with notes by Sir Joshua Reynolds (4to., York, 1783).

DUFRESNY, Charles Rivière, a French dramatist, born in Paris in 1648, died there, Oct. 6, 1724. He was descended from Henry IV. by one of the mistresses of that monarch, known as *la belle jardinière*. In consequence of his descent and his talents, he enjoyed the favor of Louis XIV., but his improvident habits were constantly involving him in embarrassments. He wrote some excellent comedies, had great skill as a landscape gardener, and was known as a pleasant companion and a wit. It is related of him that he married his washerwoman in order to avoid paying her bill. Among his comedies which obtained the most success, may be mentioned *L'esprit de contradiction*, *La coquette de village*, and *Le faux sincère*. His *Poésies diverses* are also praised. A selection of his works was published at Paris in 2 vols. in 1805.

DUGANNE, Augustine Joseph Hickey, an American poet and novelist, born in Boston in 1823. He has been a frequent contributor to the periodical press, having written between 20 and 30 novelettes and romances, and a great number of miscellaneous papers under various signatures. His poetical works consist of the "Iron Harp," "Parnassus in Pillory," a satire, the "Mission of Intellect," a poem delivered in New York in 1852, the "Gospel of Labor," delivered before the N. Y. mercantile library association in 1853, and a number of short pieces originally appearing in newspapers and magazines, which were published in a large illustrated edition, in Philadelphia, in 1856. He is also the author of the "Lydian Queen," a tragedy performed at the Walnut street theatre, Philadelphia, in 1848. Among his writings are a "Comprehensive Summary of General Philosophy," published at Philadelphia in 1845, and a "Class Book of Governments and Civil Society," printed in 1859 in New York. One of his latest productions is the "Tenant House," a work prepared from information acquired while he was a member of the legislature of New York.

DUGDALE, Sir William, an English antiquary, born in Shustoke, Warwickshire, Sept. 12, 1605, died Feb. 10, 1686. He was educated partly in the free school of Coventry, partly by his father, was made pursuivant at arms extraordinary under the name of Blanche Lyon in 1638, rose by degrees in the herald's college until he became garter principal king at arms in 1677, and was knighted. In 1641 exact drafts of all the monuments in Westminster abbey and in many of the churches of England, with copies of their inscriptions, were made under his superintendence and deposited in Sir Christopher Hatton's library. With Roger Dodsworth he projected the publication of the charters and descriptions of all the monasteries of the kingdom; and after having attended King Charles at Edgehill and followed him to Oxford, he improved a long stay in that town by collecting from the Bodleian and other libraries there materials for this great work. From the tower records, the Cottonian library, and the papers of André Du Chesne which he examined in Paris, he gathered still more information; and in 1655 the first volume of the work appeared in Latin at London, under the title of *Monasticon Anglicanum;* the 2d and 3d vols. were issued in 1661 and 1673; a new and enlarged edition, in 6 vols. crown folio, was published in 1817–'30, with plates, the cost of drawing and engraving which amounted to $30,000. This edition was reprinted at London in 8 vols. fol. in 1846. Several abridgments of the original work have been made in English. Among Dugdale's other contributions to history are the "Antiquities of Warwickshire" (fol., 1656), one of the best works of the kind ever published, and the author's *chef d'œuvre;* "History of St. Paul's Cathedral" (fol., 1658); "History of Imbanking and Drayning of divers Fenns and Marshes" (fol., 1662), undertaken at the instance of several gentlemen who were interested in the draining of Bedford Level; "*Origines Juridiciales*, or Historical Memoirs of the English Laws, Courts of Justice, Forms of Trial, Punishment in Cases Criminal, Law Writers," &c. (1666); the "Baronage of England, or an Historical Account of the Lives and most memorable Actions of our English Nobility" (3 vols. fol., 1675–'6); "A Short View of the late Troubles in England" (Oxford, 1681); "Ancient Usage in bearing of such Ensigns of Honor as are commonly called Arms" (Oxford, 1682); "A Perfect Copy of all Summons of the Nobility to the Great Councils and Parliaments of this Realme, from the XLIX. of Henry the IIId. until these present Times" (London, 1685). Dugdale also completed the 2d volume of Sir Henry Spelman's *Concilia*. His works are ad-

mirable for their accuracy, and his industry was almost incredible. His "Life, Diary, and Correspondence," with an index to his MS. collections, many of which are preserved in the Ashmolean museum at Oxford, was published at London in 1827 by William Hamper, F.S.A. —His son, Sir John Dugdale, was Norroy king-at-arms, and published a catalogue of the English nobility.

DUGONG, a herbivorous cetacean, of the genus *dugungus* (Lacépède), or *halicore* (Illiger), the only genus of its family, and the only undisputed species of the genus; the Malay name is *duyong*, and the scientific *halicore Indicus* (Desm.) or *H. dugung* (F. Cuvier). The general shape is fish-like; the head is proportionately small, and separated from the body by a slight cervical depression; there is no dorsal fin, and the horizontal tail is crescent-shaped; there are no posterior limbs, but the anterior are like cetacean paddles without any trace of nails or division into fingers. The upper lip is very large, thick, obliquely truncated, forming a blunt snout such as would be made by cutting off an elephant's trunk near the mouth; the anterior portion is covered with soft papillæ with a few stiff bristles; the lips have a corneous edging which assists it in tearing sea-weeds from the bottom. In the old animal the incisors are 2 above and none below, large, but nearly covered by the tumid and movable lip; in the young, the 2 upper permanent incisors are preceded by 2 deciduous ones, and there are 6 or 8 lower incisors which fall and are not succeeded by any permanent ones. The molars in the adult are $\frac{2\cdot2}{2\cdot2}$, simple and elliptical, in the young $\frac{6\cdot6}{6\cdot6}$, far back on the horizontal portion of the jaw; the grinding surface presents an outer rim of enamel, with the central ivory portion slightly depressed; they have no proper roots, and grow as long as they can be of use to the animal. The skin is thick and smooth, with a few scattered bristles; the color is bluish above and white beneath; the mammæ are 2, and pectoral; the fins are used not only for swimming, but for crawling along the bottom. The cranial bones are dense and large, with loose connections where any sutures exist. The intermaxillaries are very large, extending back as far as the middle of the temporal fossæ, and bent down at a right angle over the symphysis of the lower jaw, terminating nearly on a level with its lower margin; this is necessary for the accommodation of the incisors, one of which is in each intermaxillary; for this reason also the nostrils are displaced upward, different from the allied manati, so that their opening is turned up as in the typical cetacea; indeed this animal comes nearer than its congener to the whales in its forked tail, absence of nails, and superior opening of the nostrils. The whole skull (and especially the frontal bones) is comparatively short; the parietal crests are widely separated; there is no bony tentorium, no sella turcica, very few and small openings in the cribriform plate of the ethmoid bone, and the optic foramina are converted into a long and narrow canal. The lower jaw corresponds to the angle of the intermaxillaries, and is bent downward at the symphysis; on its anterior surface are 3 or 4 rough and shallow alveoli, sometimes containing rudimentary incisors, according to Sir Everard Home. The cervical vertebræ are 7, separate; the dorsals 18, with spinous processes bent back and elongated from the first to the last, and of the same length as the transverse; the lumbar 3, with long spinous and transverse processes; one sacral, to which rudimentary pelvic bones are suspended; caudals about 24, with chevron bones for the anterior $\frac{3}{4}$, and becoming flattened posteriorly. The ribs are 18, less thick and dense than those of the manati, the 1st 3 attached by cartilages to the sternum; the shoulder blade is large, with the anterior angle rounded, the posterior extended backward with a concave margin; the spine is prominent, and the acromion and coracoid processes are pointed; the humerus is short, thick, with a prominent deltoid ridge; the radius and ulna are very short, rounded, anchylosed together at each end; the carpal bones are 4, in 2 rows; the thumb is rudimentary, its metacarpal bone small and pointed; the other metacarpals are flattened, with 3-jointed phalanges. The tongue is thick, the anterior upper surface with cuticular spines, and on each side at the base a horny, retroverted, pointed process. The stomach is divided into 2 portions, the cardiac large and globular, the pyloric narrower; at the constriction between the 2 are 2 tubular cæcal prolongations as in some pachyderms, and at the cardiac end is a rounded glandular mass as in some rodents; the intestines are 14 times as long as the body, and the cæcum is simple and heart-shaped. The liver is transversely oblong, with 1 large and 3 small lobes; the gall bladder is present, elongated, receiving bile directly from the hepatic ducts; the spleen is very small and rounded. The heart has its ventricles deeply cleft, not however affecting the circulation; the capacity of the pulmonary artery is very great, to accommodate the delay of the blood in the lungs during submersion. The lungs are very long, flattened, $\frac{1}{4}$ as long as the body; the superficial air cells are large, the dorsal extent is great, the trachea divides high up, and the bronchi are long, as in marine turtles; the cartilages of the bronchial tubes are continued spirally into each other. The sense of smell must be dull; the eye is very small and convex, with a nictitating membrane beside the lids; the external orifice of the ear is hardly perceptible; the nasal openings are 2 parabolic slits, whose semi-lunar edge performs the office of a valve which can be opened and shut at pleasure; the interior of the cheeks, according to F. Cuvier, is entirely covered with strong hairs. The usual length of the dugong is from 8 to 10 feet, though it has been seen as long as 20 feet; it is found in the seas of the East Indies, especially in the Malayan archipelago, never on land, rarely if ever in fresh water, but generally in troops in shallows of the sea where the depth is not more than 3 fathoms.

Its food consists of fuci and algæ, and it browses on the marine vegetation as a cow does on land. It yields little or no oil, but is hunted by the Malays for its flesh, which resembles young beef, is tender and palatable, and is considered a royal dish. It is generally speared, and at night, especially during the northern monsoon, at the mouths of rivers, when the sea is calm. The affection of the mother for her young is very remarkable. There are doubtless several species in the Indian seas, as it is hardly probable that only one species would be found from the Philippine islands to the coast of New Holland; in the Red sea is a species called *H. tabernacularum* by Rüppell, from his belief that the Hebrews covered with its skin their tabernacle and sacred ark; this is generally considered a mere variety. In the article MANATEE will be given reasons for considering the herbivorous cetaceans as belonging rather to the pachyderms than to cetaceans, the manati coming nearer to the former, and the dugong probably nearer to the latter. (See also DINOTHERIUM.) An allied fossil genus, *halitherium* (Kaup), is found in the tertiary calcareous deposits of Europe.

DUGUAY-TROUIN, RENÉ, a French admiral, born in St. Malo, June 10, 1673, died in Paris, Sept. 27, 1736. He was at first intended for the church, but his family yielded to his inclinations, and allowed him to follow the sea as his profession. He distinguished himself as commander of a privateer in the war against England and Holland, and attracted the attention of Louis XIV., who presented him with a sword, and afterward, in 1697, admitted him to the royal navy, giving him the command of a vessel. He continued his career, and, in the letters of nobility granted him for his conduct in the Spanish war, it was stated that he had captured more than 300 merchant ships and 20 ships of war. The exploit, however, which won him the most renown, was the capture of Rio Janeiro in 1711, which brought an immense sum of money to the French government.

DUGUET, JACQUES JOSEPH, a French theologian, born at Montbrison, Dec. 9, 1649, died in Paris, Oct. 25, 1733. He officiated for many years as professor of divinity at the *oratoire*. His zeal for the cause of the Port Royalists, although tempered by moderation, which formed one of the chief traits of his character, involved him in the religious controversies of his times. His writings, which comprise nearly 20 works chiefly on theological and ethical subjects, are, without being very vigorous, conceived in the gentle and Christian tone which distinguished him in his life.

DU HALDE, JEAN BAPTISTE, a French geographer, born in Paris, Feb. 1, 1674, died Aug. 18, 1743. In 1708 he became a member of the society of Jesus, and was afterward appointed to the task of editing the letters of missionaries sent out by that society to various parts of the world, and especially to China. The result of these labors is the well-known *Lettres édifiantes et curieuses écrites des missions étrangères*, edited by Du Halde from the 9th to the 26th volume inclusive; and his *Description géographique, historique, chronologique, politique, et physique de l'empire de la Chine et de la Tartarie Chinoise* (4 vols. fol., Paris, 1735); two works of considerable interest and importance, and which contributed not a little to advance the science of geography. An English translation of the latter appeared in London in 1736 (4 vols. 8vo.), in 1742 (2 vols. fol.), and again in 1744 (4 vols. 8vo.). The *Lettres édifiantes et curieuses* have not been translated into English, but a selection from the earlier volumes appeared in London in 1743, in 2 vols. 8vo., under the title of "Jesuits' Letters."

DUHAMEL DU MONCEAU, HENRI LOUIS, a French botanist and writer on agriculture, born in Paris in 1700, died there, Aug. 23, 1782. He was educated at the college of Harcourt, where he first displayed a taste for the natural sciences. Having been appointed naval inspector, he directed his attention to the culture and preservation of wood suitable for nautical purposes, whence he was led to investigate the properties of the different species of plants and trees adapted to the climate of France, of which he drew up a catalogue arranged in the alphabetical order of their Latin generic names. His most important works are: *De la physique des arbres* (2 vols. 4to., Paris, 1758); *Des semis et plantations des arbres et de la culture* (4to., 1760); *Éléments de l'agriculture* (2 vols. 12mo., 1762).

DUIDA, a lofty mountain near the southern extremity of Venezuela. On the S. and W. it presents a perpendicular front, bare and stony to the summit. The other sides are less steep, and covered with magnificent forests. The summit, 8,500 feet above the sea, has never been reached by man. At the beginning and end of the rainy season small shifting flames are seen to play about the highest peaks, and have sometimes induced the supposition that the mountain is a volcano. At its foot is the solitary mission of Esmeraldo.

DUILIUS, CAIUS NEPOS, consul of Rome, 260 B. C., noted for his naval victory over the Carthaginians, the first success ever obtained by the Romans on the sea. The battle was fought off Mylæ in Sicily, and the triumph of Duilius is attributed to his invention of grappling irons, by means of which he attached his ships firmly to those of the enemy, and enabled his men to fight hand to hand. On his return to Rome he was honored with a magnificent triumph, and a column was raised to commemorate the event.

DUISBURG, a Prussian town, capital of a circle of the same name, in the province of the Rhine, 18 m. W. N. W. from Düsseldorf, at the confluence of the Agger with the Ruhr, on the railway from Cologne to Minden; pop. of the circle, 110,000; of the town, 12,000. It is surrounded by dilapidated walls, has a library, a botanic garden, and important manufactories of woollen and cotton, velvet, leather, tobacco, and porcelain. It has also in its vicinity extensive sugar refineries and iron forges.

DUJARDIN, Félix, a French naturalist, born in Tours, April 5, 1801. The son of a watchmaker, he was obliged to learn with little assistance the sciences which he has since been employed in teaching. From 1827 to 1834 he delivered public lectures in Tours upon geometry and chemistry as applied to the arts. During the same period he published several geological works, in one of which he first made known the curious fact that Artesian wells bring to the surface seeds and remains of insects, which have been taken from long distances and transported through subterranean passages. In 1833 and 1834 he published descriptions of the flora of the region of the Loire, and of the geology and fossils of Touraine. He then devoted himself to zoological researches, and published observations upon the *rhizopodæ*, for which he proposed a new classification. In 1839 he added extended annotations to the 3d volume of De Lamarck's "History of Invertebrate Animals," and among his later publications have been his researches upon the brain of insects, and upon the instinct of bees.

DUJARDIN, Karel, a Dutch painter, born in Amsterdam in 1640, died in Venice, Nov. 20, 1678. He was the best pupil of Berghem; studied in Italy, where his pictures were very popular; went to Lyons, got into debt, and married his landlady, whom he soon deserted, and returned to Amsterdam. He again went to Italy to escape from his wife. On his death, the Venetian senate paid him unusual honors. In spite of his dissipation he left a great number of paintings, principally of pastoral scenes and animals. His pictures are now scarce and dear.

DUKE (Lat. *dux;* Byz. Gr. δουκας, a leader), a title belonging originally to the commanders of armies. In the later periods of the Roman empire it designated the military governor of a district, and until the time of Theodosius the rank of dukes was esteemed inferior to that of counts. Subsequently their dignity greatly increased, several provinces often became subject to a single duke, and the title was not disdained by conquerors such as Alaric and Attila. The northern barbarians who invaded the vast territories of declining Rome adopted, if they had not before borrowed, the titles of duke and count; but among these martial tribes, the dukes, as military chieftains, acquired a decided preëminence over the counts, who both in the Byzantine and western empires had been employed chiefly in civil offices. Under the successors of Charlemagne, the governors of provinces generally assumed the title of duke, and achieved an almost absolute independence. The kings of France, however, succeeded in reuniting to the crown the dukedoms which had been severed from it; and the ducal sovereignty being extinguished, the name has remained in France only as a title of dignity hereditary in certain families. Prior to the revolution dukes were created by letters patent of the king, and were of 3 kinds, of which those designated as dukes and peers held the first rank, and had a seat in parliament, and certain honors and prerogatives at court. The dignity of the second class or hereditary dukes was transmissible to their male children, but that of the dukes by brevet ceased with themselves. The ducal and all other titles of nobility, abolished at the commencement of the revolution, were established again in 1806. The rank of duke in the royal family of France was superior to that of prince, inferior sometimes to that of count, and always to that of dauphin. In other great families also the title was higher than that of prince. In Germany, where the idea of sovereignty is inseparable from the ducal dignity, this title comes immediately after that of royalty. Under the emperor Henry IV. dukes began to usurp those sovereign rights which they have since exercised, and 6 dukedoms were then established. Several of the primitive dukes have exchanged their title for that of grand duke. The princes of the house of Austria bear the title of archduke. In England, it was not till the reign of Edward III. in the 14th century that dukedoms were established giving their proprietors the first rank in the British peerage, a rank which has since belonged to the title. The first person created an English duke was Edward the Black Prince, who was made duke of Cornwall in 1337, and that title is still borne by the prince of Wales. The duke of Norfolk, whose title is the most ancient of all those now in existence, except the above, is descended from Margaret, the daughter of a younger son of Edward I., who was created duchess of Norfolk in 1358. The dignity became extinct in the reign of Elizabeth, in 1572, but was revived in 1623 in the person of Ludovic Stuart, created duke of Richmond. Since the accession of George II. the title has been frugally bestowed. From that period to 1766 no person, except of the royal family, was raised to a dukedom, but in the latter year the representative of the ancient house of Percy was made duke of Northumberland; 47 years later the duke of Wellington received this title from the king, as the highest honor which could be rendered for his great services. There are now in the English peerage 21 dukes exclusive of those of the royal family. Ireland has but one duke, the duke of Leinster; of the 7 Scottish dukes, 2 are also English dukes. The title of duke, or properly prince, was originally borne by the czars of Russia, and that of grand duke or grand prince still distinguishes the princes of that house. The kings of Poland were grand dukes or grand princes of Lithuania, and the kings of Prussia were the dukes of Silesia. Italy has several sovereign dukes, as the grand duke of Tuscany, and the dukes of Modena and Parma. The title exists also in the papal states, the kingdom of Naples, the Netherlands, and in Portugal and Spain. In some of the countries of Europe it retains the attributes of sovereign power which it received in the middle ages; in others, as in England, it continues to designate the highest rank of nobility; in others, as

in France, it is but a tradition of an ancient political order.

DUKES, a co. of Mass., consisting of a number of islands in the Atlantic ocean, with an aggregate area of 118 sq. m.; pop. in 1855, 4,401. Martha's Vineyard, the largest of these islands, lies about 5 m. S. of Barnstable co., from which it is separated by Vineyard sound. A great part of the surface is occupied by forests, but there are large cultivated tracts yielding good crops of potatoes, hay, and grain. In 1855 the productions were 16,023 bushels of Indian corn, 11,586 of potatoes, 3,024 of oats, 1,810 tons of hay, and 28,382 lbs. of butter. In 1858 the county contained 12 churches and 1 newspaper office. It was organized in 1695. Capital, Edgartown.

DULAURE, Jacques Antoine, a French author and statesman, born in Clermont-Ferrand in 1755, died in Paris, Aug. 9, 1835. He studied architecture and engineering, but the work on which he was employed in the latter capacity being suspended in consequence of the war with England in behalf of American independence, he turned his attention to literature, and on the breaking out of the revolution joined the republican party. In 1792 he was elected member of the convention, in which he voted for the execution of the king, but afterward became connected with the Girondists. Compelled to fly from France during the reign of terror, he supported himself in Switzerland by his labor as an engraver. He afterward returned, and was elected to the council of 500, but retired from public life after the revolution of the 18th Brumaire, 1799. As a historian he has not the reputation of impartiality.

DULCE, Gulf of (sometimes called lake of Isabal), a large body of fresh water, extending into the state of Guatemala from the bay of Amatique, 30 m. long by about 12 broad. It seems to be a widening out, over a considerable valley, of the waters of the Rio Polochic. Between the gulf and the sea is a small lake, 15 m. long by 3 broad, called La Golfete. The waters from both reach the ocean through a narrow and picturesque stream or strait, called La Angostura or Rio Dulce. This is shut in by a rampart of rock, rising perpendicularly to a height of from 300 to 400 feet above the water. This river has a bar at its mouth, with but 6 feet of water, which deprives the gulf of most of the advantages that would otherwise attach to it, as the most convenient avenue for the commerce of Guatemala. Notwithstanding this deficiency, a considerable part of the trade of the state is carried on through the little, unhealthy town of Isabal, situated on the gulf, by means of vessels sailing from Balize. The trade of Isabal amounts to about $800,000 annually.

DULCIMER, an ancient musical instrument, resembling, if not identical with, the psaltery or *nebel* of the Jews. The modern dulcimer consists of a small box, in shape a triangle or a trapezium, containing a number of wire strings stretched over a bridge at each end, and which are set in vibration by little iron rods or wooden sticks in the hands of the performer. It is now principally used by street musicians.

DULONG, Pierre Louis, a French natural philosopher, born in Rouen, Feb. 12, 1785, died in Paris, July 19, 1838. At the age of 16 he was received into the polytechnic school, on his departure from which he studied medicine, which he practised for some time, and then devoted himself, at the suggestion of Berthollet, to physical science. After numerous analyses and researches upon chlorine and ammonia, he was led in 1812 to the discovery of the chloride of nitrogen. He was twice injured by the explosions of this new compound, and lost an eye and finger. In 1816 he discovered hypo-phosphorous acid, and introduced into the nomenclature the prefix *hypo*, to denote a less degree of oxidation. In 1820 he labored with Berzelius in the laboratory of Berthollet, and began to investigate the origin of animal heat. In opposition to Lavoisier and Laplace, who thought that animal heat was produced by the transformation of oxygen into carbonic acid, he found that in the carnivora the heat due to this cause was not more than ⅓ of the whole, and was even a smaller proportion in the herbivora, thus proving that the body must have another source of calefaction. In 1825 he was associated with Prony, Arago, Ampère, and Girard, as a commission to provide precautions against the explosion of steam boilers; and for 4 years he labored almost alone with Arago in determining the elastic force of steam at different temperatures. Dulong was a member of the academy of sciences, in which in 1832 he succeeded Cuvier as perpetual secretary for the department of physical sciences. His numerous works treat particularly of the gases, and of the nature and laws of heat.

DULWICH, a village of England, in Surrey, 5 m. S. of London; pop. in 1851, 1,904. It is chiefly remarkable for its college, founded and endowed in 1619, by Edward Alleyn, a distinguished actor. The college originally consisted of a master, warden, 4 fellows, 6 poor brethren, 6 poor sisters, 12 scholars, and 30 out members. Its income from endowment in 1626 was £800, but through the rise in the value of the estates for building sites, this gradually increased to £12,000 or £14,000, all paid to the master and trustees. By act of parliament, passed Aug. 28, 1857, a thorough reform was effected. The old officers were superseded, and a board of 19 unpaid members created to conduct the government of the college from Dec. 31, 1857. This board is in part elected by the parishes for whose benefit the institution was founded, and in part appointed by the court of chancery. One fourth of the revenue is applied to the support of aged men and women, not to exceed at first 24 in number. The educational department, consists of an upper and a lower school, to the former of which all boys between the ages of 8 and 15 are admitted on payment of a fee varying from £6 to £8, whose parents or next friends reside

in any of the parishes to which the benefits of the establishment are limited, while boys from other parishes may be received with a fee of from £8 to £10. To the lower school all boys from the parishes already alluded to are admissible as day scholars on payment of 5*s.* a quarter each when under 14, and 10*s.* a quarter each if over 14. No boy can remain in the upper school after attaining the age of 18, nor in the lower school after 16. The number of foundation scholars is not to exceed 24, and all boys, whether of the upper or lower school, may become annual candidates for this privilege, which entitles its possessors to be clothed, supported, and educated at the expense of the institution. There is a valuable picture gallery, chiefly of Italian and Flemish paintings, attached to the college.

DUMANOIR, Philippe François Pinel, a French vaudevilliste, born in Guadeloupe, July 25, 1808. He received his education in Paris, and his first play, produced at the *Variétés* theatre, *La semaine des amours*, was received with favor. His most popular pieces are *Don César de Bazan* and *Les premières armes de Richelieu*. D'Ennery was his collaborator in the former, and Bayard in the latter. From 1838 to 1841 he was manager of the *Variétés*. His *École des agneaux* obtained for him a gold medal from the minister of state in 1855.

DUMAS, Alexandre Davy (De la Pailleterie), a French general, born in Jérémie, Hayti, March 25, 1762, died in Villers-Cotterets, France, Feb. 26, 1806. He was the son of a wealthy planter, the marquis de la Pailleterie, by an African negro girl, was sent to France to be educated, and at the age of 14 enlisted, under his mother's name of Dumas, as a private in a cavalry regiment. He made himself known by his vivacious temper, handsome figure, and prodigious strength, being able, it is said, to strangle a horse between his knees; but this did not much improve his condition, as at the end of 16 years he was merely a non-commissioned officer. But while serving under Dumouriez, he performed several daring acts which pointed him out for promotion. He rapidly passed through every rank until, in Sept. 1793, he was appointed general of division. In 1796 and 1797 he served in Italy under Bonaparte, and was especially employed in the Tyrol, where, at the battle of Brixen, he alone defended a bridge against the enemy, giving the French time to come to the rescue, in consequence of which Bonaparte presented him to the directory as "the Horatius Cocles of the Tyrol." He served with no less distinction in Egypt; but upon some disagreement with Berthier, he departed for France. The ship on board of which he had embarked being obliged to put into Taranto, he was arrested by the Neapolitan government and detained for 2 years. After his release the first consul declined to give him an appointment on account of his republican opinions. He retired to the small town where he had married, and there after 3 years' sufferings died of consumption, in a state bordering on destitution.—Alexandre Davy, a French dramatist and novelist, son of the preceding, born in Villers-Cotterets, July 24, 1803. After his father's death, he was left to the care of his mother, who left him entirely to his own guidance; she sent him indeed to school, but the boy was very irregular in his attendance, learned very little French and less Latin, but became a good horseman, billiard player, fencer, and shot. At the age of 15 he was placed as copying clerk with a notary; at 18 he began to write for the stage, though none of the plays produced at this period were accepted; and at 20 the pressure of family difficulties sent him to Paris, where he applied to his father's friends to obtain employment for him. After several disappointments he was befriended by Gen. Foy, who procured for him a small office in the household of Louis Philippe, then duke of Orleans. His salary of 1,200 francs a year was a fortune to the young man; he summoned his mother to Paris; but his active mind already aimed at higher pursuits. He devoted his leisure hours to completing his imperfect education, wrote some light poems, and as early as 1825 produced at the *Ambigu* a play called *La chasse et l'amour*, the composition of which he shared with MM. Rousseau and De Leuven. His first pieces were mostly vaudevilles, brought out anonymously; tragedy also engaged his attention for a while, but he soon abandoned it. His genius was awakened by the performances of an English company, which in 1827 presented some of Shakespeare's plays in Paris; in common with several of his contemporaries, he felt that the French stage needed reform, and he resolved to be one of the apostles of the new dramatic creed. He brought out in 1828 a historical play, *Henri III. et sa cour*, constructed with utter disregard of the ordinary rules. It created a lively sensation, and though vigorously assailed by the critics was enthusiastically applauded by the public; the young author realized from it no less than 30,000 francs in a few months. *Christine*, or *Stockholm, Fontainebleau, et Rome*, another historical drama in verse, was also well received; and new pieces from his fertile pen appeared in rapid succession, which, while eliciting severe criticism, drew crowded houses. *Antony* was received with signal favor in 1831; if not the best, it is the most characteristic production of its author. *Richard d'Arlington* and *Térésa* came next. *Le mari de la veuve* appeared in April, 1832; and the *Tour de Nesle*, first represented in the following month, had the unparalleled run of over 200 successive nights; the germ of this piece had been furnished by Frédéric Gaillardet, but its details, historical character, powerful interest, and irresistible pathos belonged to Dumas. *Angèle* came out in 1833, *Catherine Howard* in 1834, and *Kean* in 1836; the latter was written expressly for Frédéric Lemaitre. *Don Juan de Maraña*, a fantastic drama, followed; then a Roman tragedy, *Caligula*, the prologue of which is in itself a poem; and finally *Mlle. de*

Belle-Isle, which is in some respects perhaps the best of his dramatic productions. Dumas was now unquestionably the first among the French dramatists. He had meanwhile entered the field as a novelist, beginning with *Isabelle de Bavière*, a romantic picture of France in the 15th century. His intention was to give, under the title of *Chroniques de France*, a series of novels, in which he intended, somewhat in imitation of Walter Scott, to treat the most interesting incidents of French history; and this project he has pursued with some perseverance. These, and his *Impressions de voyage*, narrating his travels through Switzerland and Italy, were eagerly read, and the public found that the stirring dramatist was a still more enticing story-teller. *Les trois mousquetaires* and *Le comte de Monte Christo*, both of which appeared in 1844, even excelled his theatrical works, and gave a new character to his reputation. The success of these and similar books was only equalled by the wonderful rapidity with which they were produced. Such was the confidence of Dumas in the fertility of his imagination, that in 1846 he made a contract to furnish 2 newspapers with an amount of manuscript equal to 60 volumes a year; and this exclusive of his plays and other occasional productions. Such abnormal fecundity raised the question whether he was really the author of the books bearing his name. A lawsuit in which he was involved in 1847 with the directors of the *Presse* and *Constitutionnel* brought to light the fact that he had engaged to furnish those journals with more volumes than a rapid writer could even copy; but though it is certain that he makes liberal use of the talents of assistants, he claims sufficient share in the plan and execution of every work to make it truly his own. A judicial decision finally supported this claim. He is remarkable for indefatigable industry and singular facility of composition, his daily work averaging 32 pages of an ordinary French octavo volume. Among his novels we may mention *Les mémoires d'un médecin*, or rather *Joseph Balsamo*, *Le collier de la reine*, *Ange Pitou*, and *La comtesse de Charny*, a sort of romantic review of the latter part of the 18th century. Novel writing has not withdrawn Dumas from the drama; beside adapting for the stage some of his most successful romances, he has occasionally written original pieces, such as *Un mariage sous Louis XV.*, *Les demoiselles de St. Cyr*, *Le comte Hermann*, *La jeunesse de Louis XIV.*, *La conscience*. He has found time also to publish historical books: *Louis XIV. et son siècle*, *Le drame de 93*, *Le régent et Louis XV.*, *Florence et les Médicis*. In 1852 he began the publication of his *Mémoires*, a curious autobiography, which also presents interesting sketches of literary life during the restoration; and though in itself a monument of egotism, it is full of such unfeigned admiration for his eminent contemporaries, such candor, generosity, and genuine humor, that no impartial reader can help sympathizing with its author. In March, 1856, it had extended to 27 volumes. Though a republican in politics, Dumas was on terms of friendship with the royal family of Orleans, used his influence to elicit from them acts of benevolence, not unprofitable to their popularity, and when they were exiled from France, he was bold enough to praise the young princes in several public meetings. He now tried to acquire political importance through the publication of a daily newspaper, *La Liberté*, and afterward a monthly review, *Le Mois;* but failing in this attempt, he published for 2 or 3 years the brilliant *Mousquetaire*, which he revived in 1857 under the title of *Monte Christo*, and in which he continues to publish his romances, translations, *Mémoires*, &c. Previous to 1848 his pen procured him an income of nearly 60,000f. a year, and he had undertaken, near St. Germain, the building of a small but fantastic and costly country seat, which became celebrated under the name of *château de Monte Christo*. The revolution cutting short his means, the chateau, upon which he had already expended 450,000f., was offered at auction in 1854, and sold for less than a tenth of its original cost. Dumas was married in 1842 to Mlle. Ida Ferrier, an actress of the Porte St. Martin. In 1853 he went for a time to Belgium; in 1858 he travelled in Russia, the Caucasus, Greece, and Turkey, and returned to Paris in the spring of 1859. Among his works published in 1858 are *Le capitaine Richard* (3 vols. 8vo.), *L'Horoscope* (3 vols.), *Les louves de Machecoul* (10 vols.), and *L'honneur est satisfait*, a prose comedy in one act, played at the *théâtre du Gymnase;* and a sketch of his recent travels, *De Paris à Astrakan*, appeared in 1859. Notwithstanding his bold plagiarisms, and the faults incident to his writing so much and so fast, his books enjoy a popularity, even in other languages, such as few others can boast, and it is probable that literary labor never before brought a man so large a fortune. In skilfulness of arrangement, vivacity and sustained interest of narrative, and inventive faculty, no living French author rivals him; but most of his writings pander to a morbid love of the extravagant, eccentric, melodramatic, and frivolous, and tend rather to amuse and dazzle the fancy than to produce any abiding influence upon the mind of the reader. Dumas, though the son of a white woman, presents all the characteristics of the mulatto, except color, even more strongly than his father. The English translations of his principal novels have attained an immense circulation in the United States. The most popular are the "Count of Monte Christo," the "Three Guardsmen," "Twenty Years After," the "Vicomte de Bragelone," "Margaret of Anjou," and the "Memoirs of a Physician" and its continuations.—Alexandre, a French novelist and dramatist, son of the preceding, born in Paris, July 28, 1824. At 16 he published a volume of light poems under the title of *Péchés de jeunesse*, which have been forgotten and forgiven; then he took to novel writing, and produced *Quatre femmes et un perroquet*, *Le roman d'une femme*,

Le docteur servant, *Quatre hommes forts*, *La vie à vingt ans*, which presented indications of neither extraordinary talent nor originality. But suddenly in 1851 he published the *Dame aux camélias*, which showed him under a new aspect, and made a prodigious sensation. This was nothing else than the history, slightly amended and embellished, of a woman of the town, Marie Duplessis, with whom he had been on intimate terms, and who had lately died of consumption; but it was narrated with such simplicity and pathos that it had, as the French say, a "success of tears." Two other novels, *Diane de Lys* and *La dame aux perles*, having however followed without attracting particular attention, he tried his hand at the stage. An unparalleled popularity attached to the *Dame aux camélias* under its new garb; it drew crowded and enthusiastic houses at Paris and all over France, was translated, performed, and admired everywhere, and was set to music by Verdi in his *Traviata*. In the United States several versions, "Vice and Virtue," "Camille," "The Fate of a Coquette," were presented at once on the stage. *Diane de Lys* underwent the same process of transformation, but not with the same success; and then, instead of continuing this adaptation of novels to the stage, Dumas wrote original pieces. *Le demi-monde*, performed in 1855, gave new evidence of acuteness of observation, dramatic power, and cutting wit. The same merits are perceptible in *Le fils naturel* and *La question d'argent*, which appeared in 1856 and 1857, the former a mere drama of the imagination, the latter a satire on the worship of money. Dumas *fils*, as he is generally called, presents a striking contrast to his father; instead of imprudently lavishing his wit and money, he uses both with a sparing hand.

DUMAS, Jean Baptiste, a French chemist and politician, born in Alais in July, 1800. Under the patronage of De Candolle, at Geneva, he early acquired considerable proficiency as a botanist and a chemist. In 1821 he repaired to Paris, married there the daughter of Alexandre Brongniart, and henceforth gave his undivided attention to chemistry. He was a professor in the polytechnic school, in the faculty of science, and in the school of medicine, a member of the academy of science and that of medicine, and president of the society for the encouragement of national industry; he was frequently consulted by the government of Louis Philippe, and presented several reports on important questions. After the revolution of 1848 he was elected to the legislative assembly, and was called by President Bonaparte, Oct. 31, 1849, to the ministry of agriculture and commerce, which he held until Jan. 9, 1851. After the *coup d'état* of Dec. 2, 1851, he was appointed a senator and vice-president of the municipal commission of Paris. His scientific memoirs, and his *Traité de chimie appliquée aux arts* (8 vols. 8vo.), including his organic chemistry, are highly valued.

DUMAS, Matthieu, count, a French soldier and historian, born in Montpellier, Nov. 23, 1753, died in Paris, Oct. 16, 1837. In 1780 he sailed from Brest as aide-de-camp to Rochambeau, the commander of the French troops sent to assist the Americans in their struggle for independence, and participated in nearly all the subsequent important actions of the war, including the victory of Yorktown. On the conclusion of peace in 1783, he visited Hayti; then returning to Europe, he was for two years employed in the exploration of the sea-coasts and islands of Turkey. At the beginning of the revolution he sided with Lafayette and the constitutional party; when Louis XVI. was arrested at Varennes he commanded the troops who accompanied him to Paris. As a member of the legislative assembly, he evinced wisdom, firmness of opinion, and considerable oratorical power. During the reign of terror he was arraigned and sentenced to death, but succeeded in escaping to Switzerland. After the 9th Thermidor he returned to France, and was afterward elected to the council of 500. Being proscribed as a monarchist on the 18th Fructidor, he fled to Germany, where he commenced writing his annals of military events. Returning to his country under the consulate, he was intrusted with several important missions. In 1806 he followed Joseph Bonaparte to Naples, was appointed by him minister of war, and organized the Neapolitan army. On the removal of Joseph to Spain he reëntered the French army, and actively participated in the campaigns of 1808 in Spain and 1809 in Germany. He was superintendent of the administrative service of the Russian expedition in 1812, escaped the dangers of the disastrous retreat, was made prisoner in Germany in 1813, was liberated on the peace of 1814, and served the Bourbons during the first restoration. On the return of Napoleon from Elba he refused at first to join him; but yielding to the entreaties of Joseph Bonaparte, he consented to superintend the organization of the national guards of the empire. For this he was placed on the retired list when Louis XVIII. resumed the crown. He now completed his *Précis des événements militaires*, an excellent work, giving a copious and lucid account of military operations from 1798 to 1807 (19 vols., Paris, 1816–'26). The almost total loss of his sight disabled him from continuing his work, but did not prevent him from translating a portion of Napier's "History of the Peninsular War," as a sort of supplement to it. He was elected to the chamber of deputies in 1828, actively participated in all the parliamentary proceedings, evinced decision and energy during the revolution of 1830, and was instrumental in the elevation of Louis Philippe to the throne. Beside the works above mentioned, he left some interesting personal memoirs, since published by his son under the title of *Souvenirs*.

DUMBARTONSHIRE, an E. co. of Scotland, anciently called Lennox, consisting of 2 detached portions, the larger lying between Lochs Lomond and Long and the frith of Clyde, the smaller

between the counties of Lanark and Stirling; area, 297 sq. m.; pop. in 1851, 45,103. The surface is mostly mountainous, and the soil, except in the lowlands, is poor. The best land, however, is highly cultivated, producing potatoes, grain, beans, and turnips. Large tracts are devoted to pasturage, and there are several nurseries for raising timber. The principal minerals are coal, iron, limestone, and freestone.—DUMBARTON, or DUNBARTON, on the Leven, commanded by an ancient fortress, a stronghold for at least 1,000 years, and one of the 4 stipulated to be kept in repair by the articles of the union between England and Scotland, is the capital; pop. in 1851, 4,590.

DUMDUM, a town and military station in the district of the Twenty-four Purgannahs, presidency of Bengal, British India, 10 m. S. E. of Barrackpoor and 8 m. N. E. of Calcutta. It was formerly the head-quarters of the Bengal artillery, and the seat of a training school for young officers and recruits from England. It contains handsome establishments for the officers, a large church, a free school, a depot of musketry, and an excellent cannon foundery containing a boring room in which 12 guns can be bored at once, and said to be better arranged than that at Woolwich. Though not actually the scene of revolt in 1857, Dumdum was one of the first places at which the sepoys exhibited symptoms of dissatisfaction. About the end of Jan. 1857, it became known that the native soldiers connected with the musketry school of practice here objected to the new cartridges furnished them for use with the Enfield rifle, on the ground that they were greased with cow's and hog's fat, to touch which with the lips would be sacrilege for a Hindoo and pollution for a Mohammedan. The objectionable missiles were at once withdrawn and the troops were appeased, but the grievance was taken up at other stations and became one of the causes or pretexts of the sepoy mutiny.

DUMÉRIL, ANDRÉ MARIE CONSTANT, a French physician and naturalist, born in Amiens, Jan. 1, 1774. From 1801 to 1818 he was professor of anatomy and of physiology of the medical faculty of Paris. In 1825, on the death of Lacépède, whose adjunct professor he had been for 22 years, he assumed his functions as the professor of herpetology and ichthyology at the museum of natural history. During a period of 4 years he also lectured on natural history in the *école centrale* of the Pantheon in the place of Cuvier. His works on natural history and analytical zoology are distinguished both for accuracy of details and for philosophical treatment. In his most celebrated production, *L'erpétologie générale* (Paris, 1834–'54, 9 vols. with illustrations), which contains the first attempt at a systematic description of all known reptiles, he had Bibron as collaborator. One of his best essays on the classification of fishes appeared in 1855 at Paris.

DUMFRIESSHIRE, a frontier co. of Scotland, on the Solway frith; area, 1,129 sq. m.; pop. in 1851, 78,123. A large portion of its surface is mountainous, especially in the N. and N. E. parts, where there are summits over 3,000 feet above the sea. There are many lochs, the principal of which are Castle loch of Lochmaben, and Loch Skene, 1,300 feet above the level of the sea, whose waters in making their way to the valley below form the beautiful cascade called the Gray Mare's Tail. Three rivers, the Nith, the Annan, and the Esk, give their names to the 3 popular divisions of the county, Nithsdale, Annandale, and Eskdale, and beside these there are a few smaller streams. Limestone is found in considerable quantities, and there are also mines of coal and lead, and some manufactures; but agriculture, and especially the rearing of cattle, sheep, and pigs, are the principal occupations of the inhabitants. The county was included by the Romans in the province of *Valentia*.—DUMFRIES, the capital of the county, is situated on the Nith, 9 m. from its mouth. It has a large trade in cattle and pork, and manufactures of hats, stockings, clogs, and common shoes. It was here that Bruce in 1306 assembled the Scottish nobles to deliberate on his project of gaining the throne of Scotland; here, in the chapel of the gray friars' convent, John Comyn was killed by Bruce, Feb. 10 of that year; and here was the residence of the poet Burns during the last years of his life.

DUMMER, JEREMIAH, an American scholar, born in Boston about 1680, died in Plastow, England, May 19, 1739. He was graduated at Harvard college in 1699, where he was noted for the vigor and brilliancy of his genius. With the purpose of preparing for the clerical profession, he went abroad, and studied in the university of Utrecht. On his return to America he abandoned his chosen vocation, and soon after went to England, where, as agent of Massachusetts, he rendered important services to his countrymen. He was an admirer of Lord Bolingbroke, in whose daring and reckless genius he found much that was congenial to his own character, and in intimacy with whom he adopted something of his moral and religious license. He published theological and philosophical disquisitions in Latin while at Utrecht, and his defence of the New England charters, written in England, is admirable both in style and matter. The traditions and records concerning Mr. Dummer alike testify to his remarkable powers, and his easy command of them in speaking, writing, and in intercourse with men.

DUMMODAH, or DAMMOODAH, a river of Bengal, rising in the British district of Ramgurh, flowing S. E., and then S., and joining the Hoogly on its right bank, after a course of 350 m. Its valley is to be traversed by a railway from Calcutta, and is known to abound in coal and iron.

DUMONT, PIERRE ÉTIENNE LOUIS, a Swiss scholar, the editor in French of the writings of Jeremy Bentham, born in Geneva, July 18, 1759, died in Milan, Sept. 29, 1829. His father, who had experienced great reverses of fortune, left

him in early infancy an orphan along with 3 sisters, to the care of a mother who had no resources but her talent and virtues. He was destined for the pulpit, and was ordained a minister of the Protestant church of Geneva in 1781. He distinguished himself as a preacher, at the same time taking a warm interest on the liberal side in the political controversies of his native city. In consequence of the triumph of the aristocratic faction in the spring of 1782, by means of the armed mediation of France, Savoy, and the aristocratic Swiss cantons, he went in 1783 into a sort of voluntary exile, betaking himself to St Petersburg, where his father had formerly been court jeweller. He was appointed pastor of the French Reformed church in that city; his mother followed him thither, and his sisters were honorably married there. Here also his eloquence attracted much attention; but, after a residence of 18 months, he was induced in 1784 to go to London to act in the capacity of reader to Col. Barré, who had become blind, and needed a companion. Barré was an intimate friend of Lord Shelburne, created marquis of Lansdowne, into whose family Dumont soon passed to assist in the education of the 2d son of the marquis. Here he became acquainted with Romilly and with Bentham, with the writings and ideas of the latter of whom he was so much impressed as to conceive the scheme of bringing them out in a French version. In 1788 he took a journey to Paris in company with Romilly, and through him was introduced to Mirabeau, who had made Romilly's acquaintance during a visit to London in 1784. At the request of the Genevan exiles in London, Dumont in 1789 made a second journey to Paris in company with M. Duroverai, ex-attorney of the republic of Geneva. Their object was to attain through the return of Necker to office, and the events then passing in France, support for the revolution already commenced at Geneva, and an unrestricted restoration of Genevese liberty, by cancelling a treaty between France and Switzerland, which prevented Geneva from enacting new laws without the consent of the parties to that treaty. His acquaintance with Mirabeau was renewed, and he as well as Duroverai immediately entered into very close relations with that remarkable person, assisting him in the preparation of his speeches, writing for him his published letters addressed to his constituents, advising with him as to his course, and becoming joint editor with him of a journal called the *Courrier de Provence*. The pecuniary ill success of this publication, the abatement of Dumont's sanguine hopes of political regeneration, the character of Mirabeau himself, and the attacks levelled at Duroverai and Dumont in journals and pamphlets, as being his tools, determined Dumont to leave Paris. His friends in London strongly urged his return on the ground of the antipathy then springing up in England against the French revolutionary party —a consideration of the more importance to Dumont, since he held by the appointment of Barré a sinecure under-clerkship worth about £400 a year. He quitted Paris in March, 1791, shortly before Mirabeau's death, for Geneva, but returned again in May, proceeding afterward to London in company with Thomas Paine, whom he had met in Paris, but whose acquaintance he did not keep up. In March, 1792, he again returned to Paris in company with Duroverai and Talleyrand, the latter of whom had lately visited England. Talleyrand wished to use the influence of Duroverai and Dumont in softening the feelings of the Girondists toward England, and induced them to return with him to Paris. When Talleyrand was soon after appointed one of a formal embassy to England, Dumont went with him. The embassy was very coolly received, and Talleyrand returned soon after to Paris. Dumont refused to accompany him; but in November of the same year, the French government having then passed into the hands of the Girondists, he visited Paris, on behalf and at the request of the magistrates of Geneva, that city being threatened with an attack from the French. Having completed this business, Dumont paid a short visit to Geneva, and thence returned to London. His "Recollections of Mirabeau," written some 10 years after, but which only appeared as a posthumous work, contains a very interesting account of his observations and experiences in Paris. Still enjoying, after his return to England, the hospitalities of Bowood, the seat of the Lansdowne family, and of Holland house, he now devoted himself to the labor of drawing from the manuscripts and printed works of Bentham a lucid and popular view of that philosopher's system of jurisprudence; a work, however, in which Bentham, then much engrossed with his panopticon project, declined to take any part. In 1802, during the peace of Amiens, Dumont visited Paris, and published there the first instalment of his labors, *Traités de législation civile et pénale* (3 vols. 8vo.). This work attracted great attention throughout Europe; and in 1806, while Lord Henry Petty, Dumont's former pupil, was chancellor of the exchequer, his sinecure clerkship was superseded by a pension of £500, one ground of which was the service he had rendered by this publication. In 1811 he published at London another instalment of his labors in 2 vols., *Théorie des peines et des récompenses*, of which 2 editions subsequently appeared at Paris. In 1816 he published at Geneva *Tactique des assemblées législatives;* in 1823 at Paris, in 2 vols., *Preuves judiciales;* and in 1828, *Organisation judiciale, et codification.* All these treatises reappeared in a single collection edited by Dumont, and published at Brussels in 1828, shortly before his death. However small Dumont's share in the substance of these works, they owed almost entirely to the dress in which he clothed them the attention which they attracted, and the impression which they made; and it was to his labors that Bentham was indebted for his wide-spread reputation in Europe, into the principal languages of

which, including the Russian, the *Traités de législation* were translated. When Geneva recovered her liberties in 1814, Dumont hastened to return thither. He carried with him a small fortune, married, and spent there most of the remainder of his life. Upon his first arrival he drew down upon himself a bitter storm by some criticisms which he made upon the form of government adopted by the republic, and which seemed to him too aristocratically narrow. He was chosen, however, a member of the sovereign representative council, and did what he could to liberalize and improve the institutions of his native city. Being placed on a committee to prepare rules of proceeding, he drew up a set based on Bentham's legislative tactics, the adoption of which was agreed to. In 1817 he laid before the magistrates a draft of a penal code, borrowed principally from Bentham's manuscripts, and accompanied according to Bentham's system with a running commentary of reasons. This plan was referred to a commission, of which Dumont was a member, before whom, and a sub-committee of the same, it underwent during 4 years innumerable discussions. Dumont then published it as originally offered. The lawyers made a violent opposition to it. The commentary of reasons proved a great stumbling block. It was again referred to new committees, before which it was still lingering at the time of Dumont's death. He was more successful in obtaining the establishment of a penitentiary on Bentham's panopticon plan. In his latter years he occasionally visited England, whence he still continued to draw his pension, and where he had many friends. Bentham, for some reason which does not appear, perhaps from the mere caprice of old age, finally became estranged from him, spoke of him with some asperity, and the last time he called at Queen's square place, refused to see him. This coolness much affected Dumont, who retained his reverence for Bentham to the last.

DUMONT D'URVILLE, Jules Sébastien César, a French admiral and navigator, born in Condé-sur-Noireau, May 23, 1790, died May 8, 1842. In 1816 he visited the Grecian archipelago and the shores of the Black sea, collected a number of new plants, of which he afterward published descriptions, and investigated the ruins of several ancient cities. It is said to have been at his suggestion that the French ambassador at Constantinople purchased the statue of Venus of Milo, which a peasant had lately found in his field. In 1822 he accompanied Duperrey in his voyage round the world, and returned in 1825, bringing a rich collection of insects, and a herbarium containing 3,000 specimens, about 400 of which were new. Soon after, being appointed to the command of a frigate, he was sent upon a new expedition to explore the Australian archipelago and the islands of New Zealand and New Guinea. He discovered several islands which Cook had not perceived, established the locality of the Loyalty isles, and brought home over 4,000 sketches of scenery and natural history, 10,000 specimens of various kinds of animals, and more than 6,000 species of plants. He was living in retirement, engaged in writing the account of his voyages, when the revolution of July broke out, and he was chosen to conduct the unfortunate Charles X. to England. In 1837 he undertook, with the sloops of war Astrolabe and Zélée, his third and last voyage, with the design of exploring the antarctic regions, and before his return circumnavigated the globe through the southern seas. He brought back vast collections illustrative of botany, zoology, and mineralogy. He landed at Toulon after an absence of 38 months, was raised to the dignity of rear admiral, and went to Paris to superintend the publication of the account of this voyage at the expense of the government. Only the 2d volume was published, when the author was killed, with his wife and son, in the great railway disaster on the line of Paris and Versailles. The whole work was completed under the supervision of M. Vincendon-Dumoulin, in 24 vols. 8vo., with 6 folio vols. of illustrations (Paris, 1841–'54). The departments of zoology, botany, anthropology, geology, &c., were treated by special writers attached to the expedition.

DUMOURIEZ, Charles François, a French general, born in Cambray, Jan. 25, 1739, died in Buckinghamshire, England, March 14, 1823. He served with great distinction and was frequently wounded during the 7 years' war, but his only reward was a pension of 600 livres a year and the cross of St. Louis. Impatient of an inactive life, he engaged in the war and intrigues which brought on the annexation of Corsica to France, and would possibly have prevented the partition of Poland, if his protector Choiseul had not been dismissed from power. On the accession of Louis XVI. he was put in command at Cherbourg, where important improvements were accomplished under his direction. In 1788 he was appointed brigadier-general. During the first years of the revolution, he managed to maintain friendly intercourse with the court while gaining popularity with the revolutionists. A member of the club of Jacobins, and on very good terms with the Girondists, he assumed in March, 1792, the ministry of foreign affairs in the cabinet formed by the latter. His counsels displeased the king; he also disagreed with his colleagues, who were dismissed, and he himself resigned. Assuming, Aug. 20, 1792, command of the French army on the N. E. frontier, then invaded by the Prussians under the duke of Brunswick, he succeeded by a series of brilliant operations in stopping the advance of the enemy, who were defeated, Sept. 21, at Valmy, and forced to retreat. He now crossed the frontier, routed the Austrians at Jemmapes, Nov. 6, took possession of Brussels, and within one month completed the conquest of Belgium. In the beginning of Jan. 1793, he repaired to Paris, entered into secret negotiations for the rescue of the king, which soon transpired, and he was denounced but not deprived of his commission. He now planned the conquest of Holland; but having been defeated

at Neuwinden, March 18, 1793, by the duke of Coburg, he plotted, in concert with the enemy, the overthrow of the republic. The convention then summoned him to appear at their bar, and on his refusal the minister of war, Beurnouville, and 4 commissaries were sent to arrest him in the midst of his own army. Dumouriez had them seized by some of his hussars and delivered to the Austrians; but he had mistaken the sentiments of his own troops, and no alternative was left him but to desert his army and country. This he did in company with the young duke of Chartres, the future king Louis Philippe, the indignant soldiers firing at them while they escaped. He was coldly received by the Austrians, who looked for a powerful army and not a lonely fugitive. After wandering through Belgium, Switzerland, Germany, Denmark, and Russia, he finally repaired to England, where, in consideration of some secret services, he received a pension of £1,200. He then published his *Mémoires* and a series of pamphlets on the affairs of France. He is reported to have had a large share in devising the plans of military operations against the French armies; and Wellington studied with advantage his annotations to the translation of Hagner's "Campaigns of Schomberg in Portugal," in which he pointed out the best means of opposing the French in the peninsula. He is positively charged by Montgaillard with having in 1814 given directions to the allied armies for the invasion of France. However this may be, he did not succeed in conciliating the favor of the Bourbons, and vainly solicited from Louis XVIII. a marshal's baton. He never returned to France.—See *La vie et les mémoires du général Dumouriez*, by himself (3 vols. 8vo., Hamburg, 1795).

DÜNA, or Southern Dwina, an important river of Russia. It rises near the source of the Volga in the government of Tver, flows about 500 m. with a very circuitous course, but with a general W. direction, separating the governments of Vitebsk and Livonia on the right from Wilna and Courland on the left, and discharges into the gulf of Riga near the town of the same name. Its waters abound in fish, and the river is deep enough to be navigable for the greater part of its length, but is obstructed by rocks and shoals. It is connected by canals with the Volga, the Beresina, the Niemen, and Lake Ilmen.

DUNBAR, a small seaport town in the eastern part of Scotland, in the county of Haddington, at the mouth of the firth of Forth, 28 m. E. from Edinburgh; pop. in 1851, 3,038. It has manufactories of soap, iron, steam engines, sail cloth, and cordage, and some trade. Vessels of 300 tons can enter the harbor, but the navigation is somewhat dangerous. Dunbar is a place of great antiquity, and its castle, now in ruins, was formerly a famous stronghold. It has been the scene of many interesting events in history. In 1296 the Scots were defeated here with great slaughter by the English army of Edward I. In 1337, Black Agnes, countess of Dunbar, defended the castle for nearly 5 months against the earl of Salisbury. Another important battle was fought near this town in 1650 between Cromwell with 11,000 men and Gen. Lesley at the head of a Scottish army twice as large, in which the latter was decisively defeated.

DUNBAR, William, an early Scotch poet, pronounced by Sir Walter Scott "unrivalled by any that Scotland has ever produced," born in Salton about 1460, died about 1520. He received the degree of master of arts from the university of St. Andrew's in 1479, and then becoming a friar of the Franciscan order he travelled over England and France, occasionally preaching and receiving alms, and deriving a precarious sustenance, as he himself admitted, by deceit and flattery. Weary of this errant life, he returned to Scotland, was received at the court of James IV., and delighted his royal master with his poetical compositions, and probably also with the charms of his conversation, in which he revealed both his native wit and his knowledge of mankind. His poems show a mastery of almost every kind of verse. Some of them were printed in 1508; many remained for 2 centuries in manuscript, but their fame has steadily increased since their publication at Edinburgh and Perth in 1770 and 1778. The "Thistle and Rose" was a nuptial song to celebrate the marriage of King James IV. with the princess Margaret of England. The "Dance" is a strangely imaginative poem, in which Mahoun (a name of Satan, derived from Mohammed) asks his principal ministers to entertain him with a mummery, or sort of ballet spectacle; whereupon the 7 deadly sins present themselves and deliver verses, some of which are hardly surpassed in strength and sublimity, and which are severe criticisms upon the vices of the time. The short poem of the "Merle and Nightingale" is a striking picture of the contest between earthly and spiritual affections, the merle recommending a lusty life in love's service, and the nightingale declaring that all love is lost but upon God alone. All the poems of Dunbar abound in allegory. A complete edition of them was published in Edinburgh in 1824 by Mr. David Laing, with an excellent life of the poet.

DUNCAN, Adam, lord viscount of Camperdown, an English admiral, born in Dundee, July 1, 1731, died near Edinburgh, Aug. 4, 1804. He entered the British naval service at an early age, and was promoted to a post-captaincy in 1761. He distinguished himself under Keppel in the successful attack upon Havana, and after the war with France recommenced he was in 1780 placed in command of a ship under Rodney, whose orders were to force a passage to Gibraltar through whatever impediments and relieve that fortress, then attacked by the Spaniards both by land and sea. Off Cape St. Vincent Rodney met a Spanish squadron under command of Langara, which had been sent to intercept him, and in the engagement which ensued Duncan signalized his valor by being the first to bring his ship into action, and the flag of one of the heaviest of the enemy's ships was struck to

him. In 1787 he obtained the rank of rear admiral, and in 1795 became admiral of the blue, and was appointed to the command of the British forces in the North sea. The service which his position required of him was to guard the coast of Holland and capture any merchant vessels which might venture to sea, and in this employment within 2 years he had annihilated the Dutch, or, as it was then termed, the Batavian commerce. In 1797 he succeeded in blockading a large fleet under Vice-Admiral De Winter in the Texel, when a serious mutiny broke out in his own squadron. Insubordination had become general throughout the British navy, and the ships which abandoned the fleet of Duncan joined at the Nore other mutinous ships from Plymouth and Sheerness. The English government trembled for its navy; the rebels refused all terms of accommodation, and Duncan had but 2 ships faithful to him. Yet when he advanced against the mutineers with even this force, the dissensions which had taken place among them caused several of their ships to drop the red flag and return to their duty, and the sedition was quickly ended. Duncan then resumed the blockade of the Texel, but was at length obliged to put into Yarmouth roads for repairs and provisions. There intelligence was brought to him that De Winter, the Batavian commander, had availed himself of his absence to put to sea. The English admiral immediately weighed anchor and set sail, and with a favorable wind and by a masterly manœuvre succeeded in placing himself between the Dutch and their place of retreat in the Texel, and thus in forcing them to an engagement. The two fleets met between Camperdown and Egmont, within 5 m. of the coast. De Winter was drawing fast toward the land, with the design, if attacked, to bring both fleets ashore, and thus to make it a victory to himself, it being upon his own coast. Duncan, however, began the action precipitately, without waiting to form a line, and the purpose of the Batavian vice-admiral was frustrated. De Winter maintained the contest for some time with his own flag ship after the rest of his fleet had either been captured or had quitted the action, and struck his colors only when his ship was entirely dismasted, riddled, and disabled. The loss of the English in this hard-fought battle was 1,030 killed and wounded, while that of the Dutch was considerably greater. The English took 9 sail of the line and 2 frigates. The victory created the utmost enthusiasm in England, where it was hailed as a presage of the downfall of the maritime power of Holland, long the most formidable rival of England on the seas. Duncan was created lord viscount of Camperdown, with a pension of £2,000; parliament addressed to him its thanks, and London voted him a sword of honor. He remained in active service against the Batavian republic till 1800, after which time he retired to Scotland.

DUNCAN, Joseph, an American general and politician, born in Kentucky about 1790, died in Jacksonville, Ill., Jan. 15, 1844. In the war of 1812 he took part in the brilliant defence of Fort Stephenson, under Col. Croghan, and after the close of the war he removed to Illinois. In 1824 he was elected to the senate of that state, after which he was successively representative in congress and governor of Illinois. While in the state legislature he originated the law establishing common schools.

DUNCAN, Thomas, a Scottish artist, born in Perthshire, May 24, 1807, died in Edinburgh, May 25, 1845. His paintings gained for him the appointment of professor of coloring and drawing in the academy of Edinburgh, and an election as associate of the royal academy. His picture of Charles Edward asleep after the battle of Culloden, protected by Flora Macdonald, has been frequently engraved. Among the finest of his other pieces are "Charles Edward and the Highlanders entering Edinburgh, after the Battle of Prestonpans," and the "Martyrdom of John Brown of Priesthill."

DUNDALK, a seaport town of Ireland, in the co. of Louth, near the mouth of the Castletown river, 45 m. N. of Dublin; pop. in 1851, 9,995. It has a good harbor on Dundalk bay, contains a number of schools and literary and benevolent institutions, and communicates by railway with Drogheda and Dublin. The manufactures comprise flax spinning, machinery, and agricultural implements, ropes, soap, leather, pins, and starch; and there are also flour mills, breweries, and distilleries. Its trade is important and increasing, especially in agricultural products, which are largely exported.

DUNDAS, an E. co. of Canada West, bordering on the St. Lawrence; area, 377 sq. m.; pop. in 1852, 13,811. Capital, Cornwall.

DUNDAS, Henry, Viscount Melville, a British statesman, born in Edinburgh in 1741, died there, May 27, 1811. He was of the ancient and distinguished family of the Dundases of Arniston, received his education at the high school and university of Edinburgh, was admitted a member of the faculty of advocates in 1763, displayed at once a love of gayety and dissipation and a persevering application to professional duties, and especially availed himself of every opportunity for cultivating his oratorical powers, speaking frequently as a lay member in the annual sittings of the kirk of Scotland, where he first gave signs of that manly eloquence and address which afterward made him the able coadjutor of Pitt in managing the house of commons. His celebrity as an advocate gained him the appointment of solicitor-general in 1773; he was returned to the house of commons for the county of Edinburgh in 1774, and was made lord advocate of Scotland in 1775. He was subsequently chosen member of parliament for the city of Edinburgh, which he continued to represent till his advancement to the peerage. The unpopularity and disasters of the American war, and the invectives of an opposition probably the most talented ever encountered by a British ministry, soon made the fall of Lord North's administration

certain; and though Dundas had been a supporter of that nobleman, his familiarity with affairs made him a valuable accession to the administrations of Rockingham and Shelburne, which quickly succeeded, in the 2d of which he held the office of treasurer of the navy. This ministry was obliged to give way before the combined opposition of Fox and Lord North, who, after having for 7 years mutually ridiculed and denounced each other as republican and absolutist, came together in 1783 to form the celebrated coalition ministry, the opposition to which was headed by Pitt and Dundas. The latter had been appointed chairman of a secret committee of the house of commons to inquire into the condition of British India and the causes of the war in the Carnatic, and he now made an elaborate report, extending to several folio volumes, in which he exhibited a complete mastery of the subject, and which he followed up by a bill for the better regulation of Indian affairs. The ministry, however, promising to bring in a bill upon the same subject, Dundas did not press his own proposals, and soon the ministerial pledge was redeemed by the introduction of Mr. Fox's famous East India bill. In spite of the uncompromising opposition of Pitt and Dundas, the passage of this bill was prevented only by the firmness of the king, which necessitated the resignation of the ministry. Pitt was now called to the helm of affairs with a majority in parliament against him. He was powerfully aided by Dundas, who again held the office of treasurer of the navy, and in Pitt's absence led the ministerial party in the house of commons, and whose dexterity as a debater and minute acquaintance with Indian matters were of especial value in carrying Pitt's India bill successfully through parliament against a very serious opposition. Dundas became president of the board of control under this bill, and in 1791 entered the cabinet as secretary of state for the home department. He exchanged this post for that of secretary of war in 1794, when he introduced a bill for restoring the estates in Scotland forfeited on account of the rebellion of 1745; and though the assigned reason for this measure was the valor of the Scotch in the recent wars, it was also most expedient as a means of reconciling the population beyond the Tweed to the reigning family. The investigations of Dundas into eastern affairs originated those discussions which terminated in the impeachment of Warren Hastings; but though his information on the subject was perhaps unsurpassed by that of any of his contemporaries, he neither favored the accusers nor vigorously attempted to vindicate Mr. Hastings from their invectives. He was the principal supporter of Pitt during the wars with France which followed the revolution, until he resigned his offices upon the retirement of that statesman in 1801, and on that occasion he laid before parliament a favorable statement of the condition of the East India company's affairs. In 1802 he was raised to the peerage by the titles of Viscount Melville and Baron Dunsira, and on Mr. Pitt's return to power in 1804, became first lord of the admiralty. He quickly retired from this office, having incurred a charge of violating while treasurer of the navy one of the statutes which he himself had proposed, by which the treasurer was forbidden, contrary to previous custom, to receive any perquisites or make any private or individual use of the public money. The articles of impeachment were prepared by the most celebrated leaders of the opposition, and the trial, opened in the house of lords, April 29, 1806, was conducted with imposing pomp. It resulted in the acquittal of Lord Melville by triumphant majorities, yet not, however, until after the death of Pitt. From this time Lord Melville took part only occasionally in the debates of the house of lords, and spent the most of his time in Scotland. As a statesman he was distinguished for his great capacity for business and his mastery of the subjects on which he spoke. Though his manner was ungraceful and his accent betrayed his northern birth, yet his clear and forcible statements always commanded the attention of the house. He loved society and convivial entertainments, and remembered no party distinctions on festive occasions. The city of Edinburgh contains 2 public monuments to his memory, a fine marble statue by Chantrey, in the parliament house, and a monument surmounted by a statue in St. Andrew's square.—Robert Saunders, Viscount Melville, a British statesman, only son of the preceding, born March 14, 1771, died June 10, 1851. Having previously held several high offices, he was in 1812 appointed first lord of the admiralty, which station he filled until 1827. It was during his administration that the arctic voyages were undertaken, and the navigators bestowed his name upon some of their discoveries. He was afterward again in the ministry from 1828 to 1830, when, his party having been driven from power, he retired from political life. Beside his other honors, he was lord privy seal for Scotland from 1811, and chancellor of the university of St. Andrew's from 1814, until his death.

DUNDAS, Sir James Whitley Deans, vice-admiral in the British navy, born Dec. 4, 1785. He is the son of Dr. James Deans of Calcutta, and assumed the names of Whitley and Dundas in 1808. He entered the navy in 1799, and participated with considerable activity in the naval operations of the next few years, receiving his captain's commission in 1807. He has been a member of parliament and a lord of the admiralty. At the commencement of the war with Russia he was in command of the British fleet in the Black sea, and coöperated with the land forces in the first operations against Sebastopol. His neglect to bombard the city of Odessa, and in general the slowness and cautiousness of his movements, were the subject of severe criticism in the English journals; and upon the expiration of his term of service, in Dec. 1854, he was succeeded in command of the fleet by Rear-admiral Lyons.

DUNDAS, Richard Saunders, rear admiral in the British navy, born April 11, 1802. He is the 2d son of Henry Dundas, 3d viscount Melville; entered the naval service in 1817 as a midshipman, and in 7 years obtained his commission as post-captain. He took part in the expedition against China in 1840, and in command of the Melville, 72, rendered important services at Boca Tigris and other places. From 1852 to 1855 he was a lord of the admiralty, and upon the return of Sir Charles Napier from the Baltic during the war with Russia, was appointed, in Feb. 1855, to succeed him in the command of the British fleet stationed there. In conjunction with Admiral Perraud of the French blockading fleet he bombarded Sweaborg, Aug. 9, 1855. He was again made a lord of the admiralty on the accession of Lord Derby's government in Feb. 1858.

DUNDEE, a royal and parliamentary borough and seaport town of Forfarshire, Scotland, on the left bank of the estuary of the Tay, 42 m. N. N. E. of Edinburgh; pop. in 1851, 78,931; in 1855, estimated at 90,000. It occupies the declivity of a hill, whose summit is 500 feet above the level of the sea, and is rather irregularly built. The modern streets are spacious and handsome. The principal public edifices are the churches, which are very numerous, the old Gothic tower, 156 feet high, the town hall, custom house, exchange, infirmary, lunatic asylum, industrial school, orphan institution, academy, and savings bank. In the centre of the town is a large square called the market place, from which the principal streets diverge. A triumphal arch in the Norman style of architecture has been erected to commemorate Queen Victoria's landing here in Sept. 1844. Some of the docks are very large and magnificent. King William's dock has an area of 6¼ acres, Earl Grey's of 5¼ acres, and the Victoria dock of 14⅓ acres. There are also several fine quays, capable of accommodating 70 vessels with ample berthage, and a crane near the Grey dock which can raise a weight of 30 tons. The chief manufactures are linen, which gives employment to over 20,000 hands, carpets, gloves, and leather. Ship-building, as well of iron as of wood, is also extensively carried on. The commerce of Dundee is very considerable. In 1856 there entered its port 2,323 vessels of 247,725 tons burden, and cleared thence 895 vessels of 124,701 tons burden. The registered shipping of the port was 291 vessels of 54,705 tons. It is governed by a provost, 4 baillies, and 16 councillors, and returns one member to parliament. During the reign of the Scottish kings Dundee was one of their places of residence. At the period of the reformation it was called "the second Geneva" for its zeal in behalf of Protestantism. In 1645 it was besieged, taken, and plundered by Montrose. In 1651 it was stormed by Gen. Monk, and a 6th part of its inhabitants massacred.

DUNDONALD, Thomas Cochrane, earl of, more commonly known as Lord Cochrane, an English rear admiral born Dec. 14, 1775. He is the eldest son of Archibald, 9th earl of Dundonald, who died July 1, 1831, and who was distinguished as a chemist. At 17 years of age he entered the naval service, and during the war with France signalized himself in many actions. Some of his exploits in capturing vessels against great odds are among the most brilliant achievements in the history of the British navy. In 1801 he was made a post-captain, for the capture of a Spanish frigate of far superior force to his own. In 1809 he successfully led a fleet of fire ships among the French fleet at anchor in the Basque roads, for which he was made a knight of the bath. In 1807 he was returned to parliament by the electors of Westminster, and soon incurred the animosity of the government by his radical opinions on questions of reform. In Feb. 1814, a rumor prevailed that Napoleon had abdicated, and Lord Cochrane took advantage of the rise in the funds which ensued to sell out. He was charged with originating a false rumor, and upon trial was convicted of fraud and sentenced to pay a fine of £1,000, to stand in the pillory, and be imprisoned for a year. The pillory punishment was subsequently remitted. He was at the same time expelled from parliament, and degraded from the order of the bath. His constituents, believing in his innocence, which has since been fully established, immediately returned him to parliament again, and his fine was paid by public subscription. Finding it impossible to obtain employment at home, he attached himself successively to the Chilian and Brazilian navies and to the Greeks, in each of which services he earned fresh laurels. In 1830, on the accession of William IV. and a whig government, he returned to England, and was reinstated in all his former honors. In 1851 he became admiral of the white, and in 1854 rear admiral of the United Kingdom. Lord Dundonald is a man of considerable scientific attainments, and the author of "Observations on Rural Affairs" (1847), and of "Notes on the Condition of the British West India Islands" (1851). His "Narrative of Services in the Liberation of Chili, Peru, and Brazil" appeared in London (2 vols., 1858).

DUNDRUM BAY, a bay of the Irish sea, on the coast of the co. of Down. Its entrance, which lies between St. John's point on the N. E. and the Mourne mountains on the S. W., is about 10 m. wide. The whole bay is subject to heavy swells during S. and S. E. winds. Near its N. side are 2 rocks called the Cow and Calf, connected with the mainland by a reef. The steamer Great Britain was run ashore here in 1846.

DUNES, an ancient Saxon word, still used in England to designate hills of sand along the coast which are blown together by the winds. Such accumulations are met with upon the sandy portions of the coast of the United States, and also in the interior along the shores of the great lakes. The fine sand thrown up by the waves is blown when dry by the wind into the interior, covering the surface so as to prevent all vegetation. In the department of

Landes in France, the fresh quantity of sand thus raised every year and drifted inland is estimated to cover an area of 3,000,000 square feet, encroaching a distance of 72 feet each year. At this rate, in 1500 years it would reach Bordeaux. Whole villages have already been buried in this way. Of one in Brittany only a part of a church steeple is to be seen above the sand. The prevalence of strong easterly winds may produce similar effects upon the American coast; indeed, precautions are already taken at Provincetown on Cape Cod to arrest the progress of the sands from the eastward, which threaten to fill the harbor and cover the town. The most efficient method of doing this is by planting beach grass (*arundo arenaria*, Linn.), which thrives in the sand, and binds it together by its roots, while at the same time it presents a barrier to that swept along by the wind. The height of the dunes on the eastern shore of Lake Michigan is much greater than of those upon the coast. At Provincetown they hardly exceed 60 or 70 feet in height, while the former are often several hundred feet high. Successful attempts to check the moving of the sands have been made on the coast of Gascony by sowing in the finest and most shifting of them the seeds of the broom (*genista scoparia*) mixed with those of the sea pine (*pinus maritima*). The spaces sown are covered with branches of trees until the broom takes root. This first springs up, and the young pines flourish under its shelter. The pines after some years are made profitable by their yield of tar, beside forming a barrier against the further encroachment of the sands.

DUNFERMLINE, a market town of Fifeshire, Scotland, 16 m. N. W. from Edinburgh, connected by railway with the latter city, with Glasgow, and the other large towns of Scotland; pop. in 1851, 8,577. The houses on its principal streets are generally well built, many of them having fine gardens attached to them; and as seen from a distance, the irregular outline of the town, its numerous steeples and prominent buildings, and its elevated site, give to it a striking appearance. The first factory was established in Dunfermline in 1718, and it has since become one of the most flourishing of the northern manufacturing towns. The value of its annual manufactures of table linen and cotton goods is estimated at £374,000. It has nearly 4,000 looms in constant operation. Its finest modern edifice is the abbey church, so called because it is built upon the site of the ancient church of the abbey, long the place of sepulture of the Scottish kings, and which was destroyed at the reformation. It contains beneath its pulpit the remains of Robert Bruce, which were discovered encased in lead in digging for its foundation. Charles I. of England was born there.

DUNGLISON, Robley, LL.D., an American physician and medical writer, professor of the institutes of medicine and medical jurisprudence in Jefferson medical college, Philadelphia, born in Keswick, Cumberland, England, in 1798. He commenced the practice of medicine in London, but a few years later he came to the United States, and in 1824 was elected professor of medicine in the university of Virginia, which position he held until 1833. During his residence at the university he enjoyed the friendship of President Madison, to whom he dedicated his "Human Physiology," "in testimony of unfeigned respect for his talents and philanthropy, and of gratitude for numerous evidences of friendship." For 3 years he filled the chair of materia medica and therapeutics in the university of Maryland, when he was in 1836 elected to the professorship in the Jefferson medical college which he has ever since filled. Dr. Dunglison is the author of nearly 20 volumes, generally treating of subjects connected with medical science, nearly all of which have been well received by the profession, and some of which have met with a very extended sale. Among these last may be mentioned his "Principles of Human Physiology" (2 vols. 8vo., Philadelphia, 1832); "New Dictionary of Medical Science and Literature" (2 vols. 8vo., Boston, 1833); "General Therapeutics and Materia Medica" (8vo., Philadelphia, 1836); "New Remedies" (8vo., 1839); and "Human Health" (new edition, 8vo., 1844); the sale of which has been large almost beyond precedent for works of this class. They have been introduced as text books in various colleges.

DUNKERS, or Tunkers, a religious denomination founded in 1708, in Schwartzenau, Germany, by Alexander Mack and 7 others, who, without having any knowledge of the existence of other Baptists, were led by reading the Bible to the rejection of pædobaptism. The name Dunker or Tunker (from the German *tunken*, to dip) was originally given them as a nickname to distinguish them from the Mennonites. They are also called Tumblers from their mode of baptism, which is by putting the person while kneeling head first under water, so that the motion resembles the act of tumbling. They are also called German Baptists, while they themselves take the name of Brethren, in accordance with Matt. xxiii. 8: "All ye are brethren." In Germany they established two societies in addition to the original congregation, but these societies were soon driven by persecution to Crefeld and Holland, while the congregation removed voluntarily to Friesland. Between 1719 and 1729 they all emigrated to America, to which the denomination has since been confined. They have dispersed themselves through almost every state of the Union, and are most numerous in Pennsylvania, Maryland, Virginia, Ohio, and Indiana. They now (1859) have 52 churches, and their number is estimated at about 8,000. Their church government is nearly the same as that of other Baptists, except that every brother is allowed to stand up in the congregation and exhort. When by this means they find a man apt to teach, they choose him to be their minister, and ordain him by the laying on of hands, attended with fasting and prayer and giving the

right hand of fellowship. They also have deacons, and aged women for deaconesses. From among the teachers who have been tried, they choose bishops. An elder among them is, in general, the first or oldest chosen teacher in a congregation which has no bishop. Their annual meeting, which is held about Whitsuntide, is attended by the bishops, teachers, and other representatives chosen by the congregations. The important cases brought before these meetings are, in general, decided by a committee of 5 of the oldest bishops. They use great plainness of dress and language, like the society of Friends; and, like them, they neither take oaths nor fight. They will not go to law, and until lately the taking of interest on money was not allowed among them. They celebrate the Lord's supper, with its accompanying usages of love feasts, the washing of feet, the kiss of charity, and the right hand of fellowship. They anoint the sick with oil for recovery, and use trine immersion, with laying on of hands and prayer, even while the person baptized is in the water. They believe in general redemption, though it is with them not an article of faith; but they deny that they are Universalists.—From the Dunkers, as a sect, must be distinguished the Seventh Day Dunkers, also called the German Seventh Day Baptists. They were established by Conrad Beissel, a native of Germany, who had been educated for the ministry at Halle. When a member of the Dunker society at Mühlbach (Mill Creek), in Lancaster co., Pa., he published (1725) a tract, to prove that the seventh day, and not the first day, was established by Jehovah for ever as the sabbath. This created some disturbance in the society at Mill Creek, upon which he retired from the settlement and went secretly to a hermitage on the banks of the Cocalico. Having been discovered, and joined by many of the society at Mill Creek, who settled around him in isolated cottages, the first community of Seventh Day Dunkers was established in 1728. In 1733 a monastic society was established, constituting, with the buildings subsequently erected by the community, the irregular enclosed village of Ephrata. The habit of the capuchins or white friars was adopted by both the brethren and sisters. Monastic names were given to all who entered the cloister. In 1740 there were 36 single brethren in the cloister and 35 sisters, and at one time the society, including the members living in the neighborhood, numbered nearly 300. The property which belonged to the society by donation, and the labor of the single brethren and sisters, were common stock; but none were obliged to throw in their own property or give up any of their possessions. They considered celibacy a virtue, but never required it, nor did they take any vows in reference to it. When two wished to be joined in wedlock, they were aided by the society. In the earlier days the idea of a universal restoration existed among them; but it has never been taught as an article of faith, and is always approached with great caution. They attracted the attention of the Penn family, one of whom had a tract of 5,000 acres of land near Ephrata conveyed to them, which they however refused to accept. About 1740, some 40 years before the present general system of Sunday school instruction was introduced by Robert Raikes, Ludwig Hœcker (Brother Obed) established a Sunday school which was maintained for upward of 30 years. After 1777 the society at Ephrata began to decline, and of the peculiar features of the early Seventh Day Dunkers few traces are now to be found there. A branch of the society was established in 1758 at the Bermudian creek, in York co., Penn., of which likewise but little is left. Another branch, established in 1763 at Bedford, still flourishes. Their principal settlement is now at Snowhill, on the Antietam creek, in Franklin co., Penn.

DUNKIRK (Fr. *Dunkerque*), the most northern town of France, in the department of Nord, on the strait of Dover, connected by railway with Paris and Brussels; lat. 51° 2′ N., long. 2° 22′ E.; pop. in 1856, 26,531. It is a flourishing place, with an active commerce and manufactories of soap, beet root sugar, leather, and starch, beside iron works and yards for shipbuilding. Its fisheries are also important, especially those of cod and herring, and the town contains many public buildings, including the town hall built in 1642, the church of St. Eloi, a high bell tower, hospitals, prisons, &c. The port is shallow, but the roadstead is good, and the progress of the commerce of the town since it was made a free port in 1826 has been rapid. Its origin is stated to have been a chapel founded by St. Eloi in the 7th century, around which a number of fishing huts were erected, which gradually grew into a town of some importance. Charles V. defended it with a castle, which has since been demolished. It was afterward taken by the English, who lost it again in 1558; and in 1559 it was acquired from the French by the Spaniards, whom the duke of Enghien (afterward the renowned Condé) drove out in 1646. It passed again into the hands of Spain soon afterward, and was once more taken by the French in 1658, who gave it up to Cromwell in accordance with a previous treaty. Charles II. sold it to France in 1662; Louis XIV. strengthened its defences; the English made an ineffectual attempt to bombard it in 1695; after the peace of Utrecht its fortifications were dismantled and its port was filled up, and these having been restored were again demolished at the peace of Aix la Chapelle, and again repaired in 1783. Ten years later it withstood a siege by the duke of York. Entrances in 1855, 1,239 vessels, tonnage 124,815; clearances, 1,320 vessels, tonnage 117,998.

DUNKIRK, a post village of Pomfret township, Chautauque co., N. Y.; pop. in 1855, 4,754. It is a place of considerable importance, remarkable for its beautiful situation, its commercial advantages, and its rapid growth. It stands on rising ground on the shore of Lake Erie, and has an excellent harbor, protected by a break-

water. It is a port of refuge for the lake vessels during bad weather, and possesses the advantage of being free from ice earlier in the spring than Buffalo. At the western extremity of the bay of Dunkirk is a lighthouse, and at the main channel a beacon light has been placed. Dunkirk has easy communication with both east and west, and its central position makes it a depot for the trade of a great extent of country. Hence, though incorporated only in 1837, it is already a flourishing commercial town, with every prospect of becoming in the course of a few years one of the principal ports on Lake Erie. Dunkirk is the W. terminus of one division of the New York and Erie railroad, and communicates with Cleveland, Toledo, Chicago, &c., by the Lake Shore and Michigan southern railroad lines.

DUNKLIN, a S. E. co. of Mo., bordering on Ark., bounded W. by the St. Francis river, intersected by Castor river, and having Lake Pemiscot on its E. border; area, about 700 sq. m.; pop. in 1856, 2,616, of whom 56 were slaves. The surface is occupied in great part by prairies and extensive swamps, but the soil is generally fertile where not overflowed. Efforts have been made to reclaim the sunken lands, and in 1850 an appropriation for that purpose was made by the state legislature. In 1811 and 1812 this and the surrounding counties suffered severely from earthquakes. Grain and live stock are the principal articles of export, and the productions in 1850 amounted to 77,360 bushels of Indian corn, and 2,776 of oats. There was 1 church, 1 newspaper office, and 80 pupils attending public schools. The county was named in honor of Daniel Dunklin, former governor of Missouri. Capital, Kennet.

DUNLAP, William, an American painter and author, born in Perth Amboy, N. J., Feb. 19, 1766, died Sept. 28, 1839. In his 17th year he began to paint portraits, and in the summer of 1783 executed one of Washington. The next spring he went to London, and for several years was a pupil of Benjamin West. On his return to America he attempted to paint portraits, but with such indifferent success that after 2 years he embarked in business with his father in New York. In 1805 he rented the New York theatre, and in a short time became bankrupt. Thenceforth his life was alternately devoted to painting, to literary enterprises, to the career of a theatrical manager, and to other miscellaneous pursuits. At the age of 51 only, after repeated failures, he became permanently a painter, though, in spite of considerable merit, he was never very successful pecuniarily. He executed a series of pictures on subjects previously selected by West and somewhat after his style, which were exhibited in various parts of the United States. He was also one of the founders of the New York academy of design. His "History of the American Theatre," published in 1832, and "Arts of Design in the United States," are standard works of much interest. He is the author of a number of plays, of a biography of Charles Brockden Brown, and of a "History of the New Netherlands" (2 vols. 8vo., 1840).

DUNMOW BACON. At Dunmow, in Essex, England, any married couple who for a year and a day have neither quarrelled nor offended each other in any way, nor repented in thought either sleeping or waking of their marriage, "but continued true and just in desire as when they joined hands in the holy quire," may by appearing and taking oath to the same have delivered to them as of right, according to ancient custom, a gammon of bacon. The claimants for the bacon take a metrical oath and receive a metrical charge kneeling in the church yard upon 2 hard-pointed stones, after which they are received in a chair upon men's shoulders, and carried round the site of the priory, and from the church to the house, with drums, minstrels, and various music, and the gammon of bacon borne upon a high pole before them, attended by the steward, gentlemen, and officers of the manor carrying wands, and by a jury of bachelors and maidens, being 6 of each sex, walking two and two, and by a great multitude of other people. In 1751 the bacon was claimed for the 6th time only since the origin of the custom in the 12th century, and the ceremony on this occasion was the subject of a drawing by David Ogborne. After an interval of over 100 years the custom was revived in 1855 through the instrumentality of the novelist Harrison Ainsworth, two couples receiving the bacon, in the presence of about 7,000 people. The ceremony took place again in 1857, and in 1859 three couples appeared to claim this reward of virtue. The Dunmow flitch is referred to in Langlande's "Vision of Piers Ploughman," and Chaucer's "Wife of Bath's Prologue."

DUNNING, John, Lord Ashburton, an English lawyer, born in Ashburton, Devonshire, Oct. 18, 1731, died in Exmouth, Aug. 18, 1783. His father was an attorney at Ashburton, and he entered his father's office as a clerk when only about 13 years old. At the age of 19 he went to London, where he studied law for some years, and was admitted to the bar in 1756. For a long time after this young Dunning obtained but very little practice; but, having been employed in 1762 to draw up the defence of the English merchants against the Dutch East India company, he gained much reputation, which was soon afterward increased by the able manner in which he conducted the case of Wilkes, and he ultimately became one of the most eminent lawyers of his time. In 1768 he was elected to parliament, where he sat in the house of commons until he was raised to the peerage shortly before his death. In 1770 he resigned his office of solicitor-general in consequence of the retirement of his patron, Lord Shelburne. He was a strong opponent of the administration during most of the American war; but his reputation as a politician is tarnished by his course in accepting a pension of £4,000 a year after he was raised to the peerage, although he had pre-

viously objected to the needless and burdensome amount of the pension list. In person he had many disadvantages, being short and thick-set, with a turned-up nose and sallow face. He had also a hectic cough, which often interrupted his speech, and his action and bearing were unprepossessing and awkward. Yet in spite of these defects, his eloquence, lively, fresh, and impetuous, carried all before it. He received many honors during his life, was chosen recorder of Bristol in 1766, solicitor-general in the following year, and chancellor of the duchy of Lancaster in 1782.

DUNNOTTAR, a parish in the co. of Kincardine, on the shore of the North sea, Scotland, noted for its castle, now half in ruins, which stands on the summit of a perpendicular cliff, projecting into the sea. Sir William Wallace captured it in 1296, at which period it was regarded as one of the strongest places in the kingdom; and in view of its capability of sustaining a protracted siege, the privy council selected it during the wars of the commonwealth as the depository of the regalia of Scotland. It was defended long and faithfully, after every other fortress in Britain had passed into the hands of the protector, but was finally forced to surrender. The Scottish crown, however, had meanwhile been privately conveyed away and concealed in the church of Kineff. In 1685 Dunnottar castle became the prison of many of the Covenanters. After the rebellion of 1715 it was dismantled.

DUNOIS, Jean, comte de, a French soldier, born about 1402, died Nov. 24, 1468. The natural son of Louis, duke of Orleans, the brother of Charles VI., he early gained warlike distinction under the appellation of the bastard of Orleans. In 1427, in conjunction with the celebrated Lahire, he raised the siege of Montargis, then beset by the English. In 1429 he threw himself into Orleans, which was hard pressed by a powerful army under the earl of Salisbury; by his energy and daring he upheld the spirit of the troops and citizens until they were relieved by Joan of Arc. Dunois then became a faithful follower of the heroine, sharing in all her exploits, and particularly in her victory at Patay, where the English were signally routed. The death of Joan seems to have inspired him with a still more fervent desire of serving his country against the invaders. In 1432 he recovered the city of Chartres by a bold and well devised stratagem; and in 1436 he was one of the generals who marched into Paris, to help the citizens in driving out the English. Several measures adopted by the government of Charles VII. being obnoxious to the nobles, Dunois in 1440 took part in the rebellion headed by the dauphin, and known as *La Praguerie;* but he soon became reconciled with the king, and in 1449, when the war was resumed in earnest against the English, he received the title of lieutenant-general of the king, and was placed in command of the principal force destined for the invasion of Normandy. In less than one year, chiefly by his activity, skill, and prudence, all the cities, towns, and fortresses of Normandy were recovered. In 1451 he led his victorious army into Guienne, stormed the town of Blaye on the Gironde, and within 3 months completed the conquest of that province, Bordeaux included, which for 300 years had been in the hands of the English kings. Nothing was now left them on the continent except the city of Calais and its vicinity. As a reward for his services, Dunois was appointed grand chamberlain to the king. After the accession of Louis XI., he was deprived of some of his offices, and joined in 1464 the rebellious league of the great lords, which assumed the name of "league of the public weal," and on the conclusion of the peace at Conflans, received his former offices and dignities, and various other honors.

DUNS SCOTUS, John, a scholastic theologian of the 13th century, born probably in Dunse, Berwickshire, Scotland, in 1274, died in Cologne in 1308. He was graduated at Oxford, entered the order of St. Francis, and taught theology and philosophy first at Oxford, where the number of those who attended his discourses is said to have reached 30,000, and then, his fame having spread all over Europe, at Paris. The acumen and subtlety of his reasoning obtained for him the cognomen of *doctor subtilis*. The controversies between Duns and the celebrated Thomas Aquinas upon the relation of human perception to real objects, and upon various religious doctrines, were continued for a long time by their respective disciples, who were called Scotists and Thomists. Translated into modern language, the reasoning of Duns goes to show that the knowledge derived from human conceptions and experience is real and trustworthy, inasmuch as the fundamental ideas upon which human knowledge rests are identical with the absolute substance (*universale*) of existing objects. Reality is the limitation of the absolute substance by individuation, or, in the quaint terminology of Duns, the *hæcceitas*, which might be rendered as the this-and-that-ity. Every existing being consists of substance and privation or limitation, while God is the unlimited absolute substance. The possibilities of limitations or individuations of substance are infinite, and hence follows the existence of accidental chances or occurrences; that is, the free will of individual man and his corresponding responsibility to God. The supernatural knowledge which cannot be derived from real experience is afforded by the Bible, but it is the province of philosophy to show the conformity of the teachings of the Bible with those of reason. The works of Duns were published complete in 12 vols. folio (Lyons, 1639), by Wadding.

DUNSTAN, Saint, abbot of Glastonbury, born near Glastonbury, Somersetshire, England, in 925, died May 19, 988. Under the patronage of his uncle, the archbishop of Canterbury, he passed some years at the court of Athelstan, but the jealousy of courtiers robbed him of the king's favor; he retired to Winchester, and yielding to his uncle's request devoted himself

to a monastic life. He built a cell against the walls of Glastonbury church, and there passed his time in prayer, fasting, and manual labor, transcribing manuscripts, painting, and fashioning utensils of metal for the use of the altar. In 942 Dunstan became abbot of the then ruined monastery of Glastonbury, and received from King Edmund authority to restore it at the royal charge. The reverence in which the people held him was shared by the monarch, and in the succeeding reign of Edred his power became almost absolute in the national councils. He improved his influence to restore the strictness of ecclesiastical discipline, brought the Benedictines into England, but on the death of Edred and the accession of Edwy was banished from the kingdom. His share in the story of Edwy and Elgiva has brought him into odium with all believers in that much discussed romance, the facts of which are yet unsettled. Edgar recalled the exiled abbot, doubled his honors, made him bishop of the united sees of Worcester and London, and in 959 advanced him to the primacy as archbishop of Canterbury. The prelate ruled both the monarch and the kingdom. He meted out justice with a stern hand, built up the power of the church, placed Benedictines in the livings of the disorderly secular clergy, and forced the king to do a 7 years' penance for a sin of licentiousness. On Edgar's death his influence raised Edward to the throne, to the exclusion of a younger son, Ethelred; but on the accession of the latter in 978 his power was broken, his threats were no longer regarded, and full of mortification he retired to Canterbury, and there died. He was a man of great talents, energy, and strength of purpose, and devoted all his powers to the advancement of the papal supremacy. Of the writings attributed to him, only the "Concord of Monastic Rules" is known to be authentic.

DUNSTER, Henry, the first president of Harvard college, inaugurated as such, Aug. 27, 1640, died Feb. 27, 1659. He was president until 1654, when, having become a supporter of the principles of the modern Baptists, he was persuaded to resign his office. He was respected as a modest and pious man, and esteemed an excellent oriental scholar.

DUNTON, John, an English bookseller and author, born in Graffham, Huntingdonshire, May 4, 1659, died in 1733. His father, who was a clergyman, designed him for the church, but the boy's tastes not fitting him for that profession, he was apprenticed to a bookseller in London. He was afterward engaged in business for himself, came to New England in March, 1686, with a cargo of books, where he remained about 8 months, and after his return embarked again in business, with little success. With some assistance he conducted a weekly publication called the "Athenian Mercury," resolving all the most nice and curious questions proposed by the inquiring, of which 20 volumes appeared. A selection was made from this in 4 volumes, called the "Athenian Oracle." He wrote voluminously on religion, ethics, and politics, filling his works with information which is no less entertaining for being subservient to the author's vanity. He gives us, in his "Life and Errors of John Dunton" (London, 1705 and 1818), the "lives and characters of more than 1,000 contemporary divines and other persons of literary eminence," and relates many curious facts in relation to the bookselling business, describing the ministers, booksellers, and other citizens of Boston and Salem.

DUODECIMAL, proceeding by twelves, a term properly applied to an arithmetical scale using 11 digits and a cipher, such as has been zealously advocated in our own day as an improvement upon ordinary decimal arithmetic. Thus if we use ɛ for ten, and ɡ for eleven, the number 275 may be written 1ɛɡ. But the term duodecimal is also given to the system of compound numbers, sometimes used by artificers in calculating surfaces and solidities from measures taken in feet and inches. Duodecimals in the second sense are considered by most mathematicians as worthless, and in the first sense as not having sufficient superiority over decimals to counterbalance the immense inconvenience of making a change.

DU PAGE, a N. E. co. of Ill., drained by the E. and W. branches of Du Page river; area, 340 sq. m.; pop. in 1855, 12,807. It has a level surface, occupied in great part by prairies. The soil is exceedingly fertile, and produces Indian corn, wheat, oats, and pasturage. In 1850 it yielded 259,283 bushels of wheat, 198,363 of Indian corn, 230,450 of oats, and 23,617 tons of hay. The county contained 17 churches and 2 newspaper offices, and there were 850 pupils attending public schools. The Illinois and Michigan canal, which passes along the S. E. border, and the Chicago and Galena and one or two shorter railroads, are its chief internal improvements. Capital, Napierville.

DUPATY, Charles Marguerite Jean Baptiste Mercier, a French jurist, born in La Rochelle, May 9, 1746, died in Paris, Sept. 17, 1788. He advocated the privilege of the French parliament against the encroachments of the crown, and was imprisoned in consequence. He produced a work on criminal law reform, *Réflexions historiques sur le droit criminel*, followed by *Lettres sur la procédure criminelle de France*, and kindred publications, containing views subsequently embodied in the *Code Napoléon*.

DUPERREY, Louis Isidore, a French naval officer, born in Paris, Oct. 22, 1786. He entered the navy in 1802, and served actively during the wars of that period. His first important scientific labor was in 1811, when he made a hydrographic survey of the coast of Tuscany. In 1817 he embarked in Freycinetz's voyage of discovery, and to him were due the hydrographic operations and charts of that expedition. In 1822 he was placed in command of a new expedition for scientific observation in Oceanica and along the shores of South America. But his most

important researches have been concerning terrestrial magnetism. He determined upon charts the place of the magnetic poles, and fixed the southern magnetic pole at the point where the observations made on the last expedition of Dumont d'Urville had demonstrated it to be.

DU PETIT-THOUARS, Abel Aubert, a French vice-admiral, born Aug. 3, 1793. He entered the navy at an early age, and the ability which he displayed on various occasions led to his rapid promotion. From 1837 to 1839 he was engaged in circumnavigating the globe. The description which he gave of Tahiti on his return to France called attention to that island, and eventually led to the protectorate of France over it. The English missionary Pritchard, in order to prevent the ascendency of France, instigated the natives to attack Du Petit-Thouars. Pritchard was finally driven from the island, which led the English government to insist upon the recall of the French admiral. Guizot not only yielded to this demand, but caused the chambers to vote an indemnity to Pritchard. Much public sympathy was expressed toward Du Petit-Thouars, who declined the ovations intended for him. In 1846 he became vice-admiral, and in 1849 member of the board of admiralty. In the latter year he was elected to the legislative assembly by the department of Maine-et-Loire. His principal work is his *Voyage autour du monde*, in 10 vols., with 180 illustrations (Paris, 1840.)

DUPIN, André Marie Jean Jacques, a French lawyer and politician, born in Varzy, department of the Nièvre, Feb. 1, 1783. He was early distinguished as a learned lawyer and an able speaker. A member of the chamber of deputies in 1815, he opposed in secret session the motion to proclaim the son of Napoleon I. emperor after his father's second abdication. The same year, in conjunction with Berryer, he was appointed counsel for Marshal Ney, and gaining great popularity by his defence of his illustrious client, was chosen to defend many political offenders. His pleadings were extensively reported in the opposition papers, and eagerly sought for by the public. Among the most famous were his speeches in behalf of Béranger the poet, in 1821, and of the *Journal des débats* newspaper, on the eve of the revolution of 1830. After that event it was in great part through Dupin's exertions in the chamber of deputies that the duke of Orleans, whose legal adviser he had been since 1817, secured the crown. The office of attorney-general in the court of cassation was his reward, and he became a member of Louis Philippe's first cabinet. In 1832 he was elected to the presidency of the chamber of deputies, which office he held for 8 years. On the revolution of 1848 he made at first some effort in behalf of the Orleans family; but perceiving the turn events were taking, he desisted, and as a proof of his devotion to the new system, he moved the court of cassation to declare that henceforth justice would be administered in the name of the people. In the constituent assembly he was a member of the committee on the constitution, but left the framing of that instrument to Cormenin and Marrast. The legislative assembly elected him president. He made some show of opposition to the government of Louis Napoleon, but was taken unawares by the *coup d'état* of Dec. 2. He declined all participation or responsibility in the parliamentary resistance, and retained his office of attorney-general. This, however, he resigned on the publication of the imperial decrees of 1852, confiscating the Orleans property; in 1857 he was reinstated. The eldest of 3 brothers, he is generally known as Dupin the elder. His writings on legal subjects are very numerous.—Charles, brother of the preceding, a French geometer and statistician, born in Varzy, Oct. 6, 1784. He entered the navy as an engineer, and was actively employed in France and the Ionian islands. In 1812 a series of scientific papers attracted the attention of the academy of sciences. During 1814 and 1815 he evinced liberal opinions, but finally adhered to the Bourbons. In 1816 he visited Great Britain, to examine the financial, commercial, industrial, naval, and military resources of the United Kingdom. The results of his travels, which he continued for more than 4 years, appeared in his *Voyages dans la Grande Bretagne* (Paris, 1820–'24), and in his *Force commerciale de la Grande Bretagne* (1826). He caused gratuitous lectures on the application of science to industry, for the benefit of workmen and artisans, to be established in the *conservatoire des arts et métiers* at Paris, and received the appointment of professor of geometry in that institution. His services were rewarded with a barony. In 1825 and 1826 he instituted a private inquiry into the intellectual and productive resources of France, the results of which he embodied in his *Situation progressive de la France depuis* 1814. In 1828 he was elected to the chamber of deputies. He adhered to the government of Louis Philippe, and was promoted to a peerage in 1838; but he nevertheless continued his regular course of public lectures. After the revolution of Feb. 1848, he was elected to the constituent and legislative assemblies, voted and acted with the majority, and on the overthrow of the republic became a supporter of the present imperial government, under which he is a senator.

DUPLEIX, Joseph, a French soldier and statesman, born about 1700, died in 1763. At the age of 20 he was sent as an agent to Pondicherry, and in 1730 was appointed to direct the declining settlement of Chandernagore. Within 10 years he had acquired an immense fortune, and had changed the insignificant town, which Chandernagore had become before his arrival, into one of the finest and most flourishing cities of India. In 1742 he was made governor-general, and being thus placed at the head of French affairs in India he gave scope to his ambition, established commercial relations with every district of Hindostan, with the Red sea, the Persian gulf, and even with

Thibet, and received Indian princes or their ambassadors with splendid pomp. He had already begun to disturb the English East India company when war broke out between England and France. At the commencement of hostilities Labourdonnaie, governor of the Isle of France, appeared in the Indian seas at the head of a squadron armed at his own expense and took possession of Madras. His instructions, however, forbade him to keep any conquest, and he therefore accepted a capitulation which secured the payment to him of a heavy ransom. But Dupleix, to whom Madras would be of immense value, determined to possess himself of it at whatever cost, and therefore broke the terms of the capitulation, seized the town, imprisoned Labourdonnaie, and sent him to France under accusation of treason. The English, alarmed at the energy and unscrupulousness of the French governor, attacked Pondicherry by land and sea. The energy of Dupleix increased with every difficulty, and, serving at once as captain and engineer, he forced the English commander Boscawen to raise the siege 40 days after he had opened the trenches. The fame of this victory spread through all India, and gave the native princes a high idea of the valor of the French. The war was soon terminated by the treaty of Aix la Chapelle, and India being then almost in a state of anarchy, Dupleix sought to make territorial acquisitions by interfering in the politics of other states. Upon the death of the Nizam-ul-mulk, who had made himself independent in the Deccan, Dupleix resolved to put upon the vacant throne Mirzapha Jung, who was willing to receive the crown from the hands of the renowned defender of Pondicherry, and to grant in return large territorial and pecuniary possessions. At the same time and with the same motive he supported Chunda Sahib as nabob of the Carnatic. He was successful in both schemes, defeating all opposition, and gained a triumph as yet unprecedented in India. The English now set up a rival candidate for the throne of the Deccan, and increased their forces under Lawrence and Clive. Dupleix, who was extending his views even to Delhi, imparted to the court of Versailles a plan of operations which was to open the way to this capital of the Mogul empire. But the French company, though delighted with his former exploits, were alarmed at his new projects, and the reënforcements of men and vessels which he asked were refused; at the same time an order was given him not to push further his acquisition of territory. Thus unsupported, the English and native forces gathered about him, yet he maintained the war at his own expense and that of his friends. He was still formidable to his enemies, though he had suffered severe disasters, when the French government, urged by English influence, and mistaking its own interests in India and the genius of Dupleix, recalled him from his command. He arrived in France in 1755, and after having so long exercised the authority and lived with the splendor of an eastern sovereign, died of chagrin at having solicited in vain the payment of the debts due him from the company which he had loaded with riches.

DUPLIN, a S. E. co. of North Carolina, watered by the north branch of Cape Fear river; area, 670 sq. m.; pop. in 1850, 13,514, of whom 6,007 were slaves. It has a level surface, with several forests of pitch pine. The general character of the soil is sandy, but there are fertile tracts in the valleys of the streams. The staple productions are cotton, grain, potatoes, lumber, tar, and turpentine. Sweet potatoes are more extensively cultivated here than in any other part of the state. In 1850 the county yielded 461 bales of cotton, 372,530 bushels of Indian corn, and 253,097 of sweet potatoes. It contained 12 saw mills, 40 tar and turpentine manufactories, and 19 churches. The Wilmington and Weldon railroad intersects it. Formed in 1749. Capital, Kenansville.

DUPONCEAU, Peter Stephen, an American lawyer and scholar, born in St. Martin, Isle of Ré, France, June 3, 1760, died in Philadelphia, April 1, 1844. His father, who held a military position, had early determined that he should follow the same profession; but owing to an imperfection in his sight it was found necessary to abandon these plans, and his mother was then anxious that he should be educated for the priesthood. To this his father would not consent; and on its being decided that he should receive a collegiate education before his profession was definitely settled upon, he was in the autumn of 1773 sent to a college of Benedictine monks at St. Jean d'Angély. In this institution he continued for 18 months, when returning home he found that his father had just died. His mother and other members of his family now prevailed upon him to study for the church. Through the offices of the bishop of Rochelle, who was a friend of his father's family, he was sent to the college of Bressuire in Poitou; but the treatment he received there induced him to sever his connection with the college, and on Christmas day, 1775, he set off for Paris, where he designed to rely upon his own exertions for a livelihood. Here he arrived early in January, to use his own words, "at the age of 15, with a light heart and a still lighter purse," but "full of hope." He was kindly received by many of the former friends of his father, and he continued to enlarge his circle of acquaintance, among whom were the baron de Montmorency, the count de Genlis, and M. Beaumarchais. He principally engaged in the translation of English books for republication, being a good English scholar, and enthusiastically fond of the language and its literature, which latter he esteemed much above the French. For a time he was secretary to Court de Gébelin, and afterward to Baron Steuben, with whom he came to the United States. They reached Portsmouth, N. H., Dec. 1, 1777. So well did Duponceau speak the language, that hardly had he arrived in the

country, as he himself has informed us, "when he felt at home;" and letters are still preserved written by him at this time, which show a remarkable fluency and command of English. In Jan. 1778, Steuben, having previously communicated by letter with Gen. Washington, set off with his secretary for York, Penn., where congress was then in session. To this body he offered his services, and asked commissions for Duponceau and Depontière, a Frenchman of his suite, and on Feb. 18, 1778, the former became captain by brevet in the American service. On the following day Steuben, accompanied by his suite, set out for the camp at Valley Forge, where they were received with great cordiality by the commander-in-chief. On May 5 following Steuben was appointed inspector-general of the army, with the rank of major-general; and in all his movements he was accompanied by Capt. Duponceau, up to the close of the campaign of 1779, when the army went into winter quarters in Philadelphia. Here Duponceau was threatened with a pulmonary disease, which for some time prevented him from performing active duty. Toward the close of 1780 he accompanied Steuben to the south, but renewed ill health forced him to return to Philadelphia early the next summer, taking with him a letter from the baron to the president of congress, recommending him in the highest terms. On July 25, 1781, he took the proper oaths and became a citizen of Pennsylvania. Robert R. Livingston, who had recently been appointed secretary of foreign affairs by congress, gave him a place in his office in Oct. 1781, which he held until June 4, 1783. The war having closed, he now commenced the study of the law, and was admitted to the bar in Philadelphia in 1785. In 1788 he was married. At an early day he acquired an extensive practice as well in the courts of Pennsylvania as in those of the United States, including the supreme court, where he was engaged in many important suits. His professional life was a successful one, and as the pecuniary result of his labors he left a handsome fortune at his death. So high an opinion did President Jefferson entertain of his legal abilities that he tendered to him the office of chief justice of Louisiana, which, however, he declined. In addition to the absorbing duties of his profession, he devoted throughout his life no inconsiderable attention to philology. As chairman of the committee of history, moral science, and general literature of the American philosophical society, in 1819 he made a report to that institution on the "Structure of the Indian Languages," which was printed, and at once gave him a high position in this department of knowledge. In May, 1835, he received from the French institute, for a "Memoir on the Indian Languages of North America," the linguistic prize, founded by the count de Volney. In 1838 he published "A Dissertation on the Nature and Character of the Chinese System of Writing," in which, in opposition to generally advanced opinions, he held that the written language was lexigraphic, representing sounds and not ideas. For several years he was much interested in an effort to introduce into the United States the production and manufacture of silk. He published several essays, letters, and reviews on the subject, expended several thousand dollars as well as much valuable time in the cause, but without success. His other writings are of a miscellaneous character, comprising an extensive range of subjects; among which may be mentioned original treatises on points of law; translations from the Latin, German, and French on similar subjects; various treatises on philology; numerous contributions to American history, including a translation of "A Description of New Sweden," by Thomas Campanius Holm. He was a member of more than 40 literary and scientific institutions of Europe and America, including the American philosophical society, the historical society of Pennsylvania, and the Philadelphia Athenæum, of which 3 institutions he was the presiding officer at the time of his death.

DUPONT, A. Pierre, a French song writer, born in Lyons, April 23, 1821. His father was a mechanic, who apprenticed him to a silk weaver, but he soon left weaving and obtained a clerkship in a banking house. His first book, *Les deux anges*, interested in his behalf M. Pierre Lebrun, a member of the French academy, who in 1841 saved him from the conscription by opening a subscription which enabled him to procure a substitute. *Les deux anges* afterward won a prize at the academy, but it was scarcely noticed, and the young poet was still unknown when he published a collection of rural poems entitled *Les paysans*, mostly songs, the music of which he also composed. Among these, *Les bœufs* attained an immense popularity, and Pierre Dupont was proclaimed the true successor of Béranger. On the revolution of 1848 the poet leaned to the new socialist doctrines, and wrote several songs which were somewhat imbued with them. His poems have been collected and published under the titles of *Cahier de chansons*, *La muse populaire*, and *Chants et chansons, poésie et musique* (Paris, 1850–'54).

DUPONT DE L'ÉTANG, Pierre, count, a French general, born in Chabannais, department of Charente, July 14, 1765, died Feb. 16, 1838. Appointed brigadier-general in 1793 and general of division in 1797, he joined Bonaparte on the 18th Brumaire, contributed to the victory of Marengo, and subsequently at the head of 14,000 troops, defeated 43,000 Austrians on the banks of the Mincio. He won new laurels in 1805 and 1806 during the campaigns in Austria and Prussia. With but 5 battalions he routed 22,000 of the enemy at the bridge of Halle, and afterward by a bold movement against the Russian imperial guard decided the victory of Friedland. Sent to Spain in command of the army which was to conquer Andalusia, he was successful at first, but permitted himself to be surrounded in the Sierra Morena by a Spanish army, and consented to sur-

render with his whole force—an event known as the capitulation of Baylen, and stigmatized as shameful by Napoleon. He was arrested on his return to France, and by an imperial decree of 1812 was degraded from his rank, sentenced to imprisonment, and sent to the fort of Joux in the Jura. The fall of the empire restored him to liberty, and his supposed hatred of the emperor led to his appointment as minister of war, and the cancelling of all the proceedings against him; but he was soon dismissed from that office. After the 2d restoration he was appointed member of the privy council. His native department elected him several times to the chamber of deputies. A man of literary taste, he wrote several poems and a translation in verse of the odes of Horace; he also published pamphlets on the recruiting system and the campaign of Austria, and critical observations upon Montgaillard's *Histoire de France*.

DUPONT (DE L'EURE), Jacques Charles, a French politician, born in Neubourg, department of Eure, Feb. 27, 1767, died in Paris, March 3, 1855. First an attorney at the parliament of Normandy, he became a magistrate, and was finally promoted in 1811 to the presidency of the high court at Rouen, which post he held until 1818. He commenced his political career in 1798 in the council of 500, was a member of the legislative corps in 1813, and deputy to the chamber in 1814. His motions and speeches during this period pointed him out as an unflinching adherent of liberal institutions. He was constantly reëlected by his department from 1817 to 1848, and during this long political career won the esteem of both friends and opponents. On the revolution of 1830, he was prevailed upon by Lafitte to take the ministry of justice; but his independence and rigidness of principle could hardly please Louis Philippe, and he left the office at the end of 4 months to resume his seat among the opposition in the chamber of deputies. In Feb. 1848, he was unanimously elected president of the provisional government, but old age interfered with his activity. He was elected, however, to the constituent assembly, and in 1849 retired to private life.

DUPONT DE NEMOURS, Pierre Samuel, a French economist, born in Paris, Dec. 14, 1739, died in Delaware, Aug. 6, 1817. An adherent of Quesnay, he became the expounder of his doctrine. He was the assistant of Turgot during his short tenure of the ministry of finance, 1774–'6. Under the ministry of Vergennes he was employed in framing the treaty of 1783, in which the independence of the United States was formally recognized by England. In the constituent assembly in 1789 he advocated liberal principles, but opposed the harsh measures of the revolutionists; after the fall of the Girondists he was imprisoned, but was saved by the revolution of the 9th Thermidor. In the council of 500 he was suspected of favoring the royalists. In 1795 he repaired to the United States, and returning to France in 1802, became a contributor to several periodicals, and published pamphlets, among which was an essay *Sur l'éducation nationale dans les États Unis d'Amérique* (Paris, 1812). On the first overthrow of the empire he was appointed secretary to the provisional government. On the return of Napoleon he left France in disgust, repaired to the state of Delaware, where his sons had established a manufactory of gunpowder, and passed his latter years there.

DUPPA, Brian, an English bishop, born in Lewisham, Kent, in 1588, died in Richmond in 1662. He was educated at Westminster school, and at Christchurch, Oxford, and after taking orders travelled in France and Spain. He was successively dean of Christchurch, chancellor of the diocese of Salisbury, chaplain of King Charles I., tutor to Charles, prince of Wales, and his brother James, duke of York, bishop of Chichester, and in 1641 bishop of Salisbury. He accompanied Charles I. during the conflicts of the civil war, and was highly esteemed by that monarch. He lived in retirement during the protectorate, but was promoted by Charles II. to the bishopric of Winchester, and made lord high almoner. A short time before his death he received a visit from Charles II., and gave his blessing to that king with great solemnity. He published several works of practical piety, of which the "Soul's Soliloquies," a sermon preached before Charles I., is the most important.

DUPRAT, Pascal, a French publicist, born in 1812, was professor of history at Algiers from 1839 to 1844, and wrote an *Essai historique sur les races anciennes et modernes de l'Afrique septentrionale* (Paris, 1845). Coöperating with Lamennais and other reformers, he was sent to the national assembly in 1848, and on June 24 he moved the resolution which conferred the executive power upon Gen. Cavaignac. After the *coup d'état* of Dec. 2, 1851, he was arrested, and banished from France in 1853. He has since resided in Brussels, and more recently in Lausanne.

DUPREZ, Gilbert Louis, a tenor singer, born in Paris, Dec. 6, 1806. He was educated at the *conservatoire*, and made his début at the Odeon in Dec. 1825. His success not fulfilling his expectations, he went to Italy in 1828, and for 9 years sang in the principal cities with constantly increasing reputation. In 1837 he was able to return to Paris and dictate his own terms to the director of the grand opera, where he made his first appearance as Arnold, in the opera of "William Tell," April 17. His predecessor, Nourrit, a celebrated tenor singer, was so affected by the applause which greeted this representation, that he eventually committed suicide. Thenceforth, until his retirement from the stage, Dec. 14, 1849, the career of Duprez was a series of triumphs. No tenor singer has ever been held in higher estimation by French audiences, among whom his manner of sounding the *Ut de poitrine* in "William Tell" produced an extraordinary effect. Duprez is an accomplished musician, and has published a work entitled the *Art du chant*. Several tenor *rôles* have been written for him. A new opera for which he fur-

nished the music and his brother Édouard the libretto was accepted by the manager of the Lyons opera in 1859.—His daughter CAROLINE (born in Florence in 1832, and married in 1856 to M. Van den Heuvel) made her début in 1850 in the *Sonnambula* at the Italian opera, and has held since 1852 a leading position at the *opéra comique* in Paris.

DUPUIS, CHARLES FRANÇOIS, a French scholar and philosopher, born at Trie-le-Château, Normandy, Oct. 16, 1742, died near Dijon, Sept. 29, 1809. The son of a country schoolmaster, he was first instructed in mathematics and land surveying; and afterward, through the protection of the duke de la Rochefoucauld, was enabled to complete a course of collegiate studies at Paris. He was made professor of rhetoric at the Lisieux college when only 22 years of age, and delivered in 1780, in the name of the university of Paris, a funeral oration in honor of the empress Maria Theresa. In 1787 he was promoted to the chair of Latin eloquence in the college of France. Meanwhile he attended the scientific lectures of the great astronomer Lalande, with whom he became intimately acquainted; and these studies, combined with his thorough knowledge of ancient mythology, led him to undertake to trace the origin of all religions to astronomy. Ancient divinities, he asserted, were but constellations; the names of mythological gods were those of the stars; and the strange adventures ascribed to the former merely an allegorical account of the various motions of the latter, and their relations to each other. The theory was first presented by him in several papers which appeared in the *Journal des savants;* was more fully expounded in a 4to. volume printed in 1781, under the title of *Mémoire sur l'origine des constellations et sur l'explication de la fable par l'astronomie;* and then, after 14 years of unremitting labor, was unfolded in all its mysteries and particulars in the bulky work, *L'origine de tous les cultes, ou la religion universelle* (3 vols. 4to., Paris, 1795). This performance did not command the popularity which its author had anticipated; he therefore, in 1796, published an abridgment, which was more acceptable, and has been frequently reprinted. Amid his literary pursuits, Dupuis had been somewhat unwillingly drawn into politics. A deputy to the convention, he acted with the moderate party; he was a member of the council of 500, and a candidate for the directorship. On the establishment of the empire he returned to private life, and in 1806 published his *Dissertation sur le zodiaque de Tentyra ou Denderah*, which forms the complement of his great work.

DUPUYTREN, GUILLAUME, a French surgeon, born at Pierre-Buffière, Oct. 6, 1777, died in Paris, Feb. 8, 1835. He attracted attention in his boyhood by his beauty, intelligence, and haughty character, and at the age of 12 was placed by a military officer, who was fascinated by his peculiarities, in the college of La Marche at Paris. He there engaged in literary studies, but was rebellious to discipline, abandoned Latin for the sciences, and became enthusiastic only after undertaking the study of medicine. Repeating the words of Cæsar, that it is better to be first in a village than second at Rome, he resolved to be unsurpassed in the art of surgery. At the age of 18 he was appointed assistant dissector in the *école de santé;* and in 1801, after a brilliant examination, he became chief of the faculty of medicine. The indisputable superiority of Bichat at this time was a spur to his ambition, and he displayed an unprecedented skill and activity in dissections. He became successively surgeon of the second class in the Hôtel Dieu; inspector-general of the university; professor of medical practice; and in 1815 surgeon-in-chief of the Hôtel Dieu. Having now absolute power in the oldest and wealthiest hospital of France, he regularly passed 5 hours in the morning in performing operations in the presence of over 400 students. With a severe exterior, and a grave and mysterious manner, he kept his audience in perfect stillness. With scalpel in hand and the patient before him, he delivered lectures which were unequalled in Paris for clearness of exposition, elegance of expression, or novelty of ideas. He was never gentle, and never smiled except when he sought to draw from a patient the symptoms of his malady; he seemed to possess only practised senses and a severe logic; and the masterly unconcern with which he framed his discourses in the midst of suffering and death, gained for him a peculiar reputation. Upon the assassination of the duke de Berry, in 1820, Dupuytren was called to the Tuileries for consultation, and 3 years later he was made first surgeon to the king. But though the transition from the Hôtel Dieu to the court increased his renown, yet his proud, silent, and capricious character became the object of innumerable epigrams and calumnies. His health failed in 1833, and he repaired to Italy, but could not be restrained from renewing his studies and observations in Rome. He died after much suffering, which excited rather his curiosity than complaints or disquietude, and left a part of his large fortune for the foundation of a chair of pathological anatomy in the faculty of medicine in Paris, and of a museum which now bears his name. His principal works have been collected in an edition entitled *Leçons orales.* He simplified many surgical operations, and made some valuable innovations in the art.

DUQUESNE, ABRAHAM, a French naval officer, born in Dieppe in 1610, died in 1688. He was the son of a seaman, was educated in his native town, early entered the naval service, and gained distinction in several encounters with the Spaniards, especially in 1637 off the Lerins isles, in 1641 off Tarragona, and in 1643 off Cape Gata. On the suspension of hostilities he offered his services to Sweden, then at war with Denmark, received the rank of vice-admiral, and completely defeated the Danish fleet under the command of King Christian IV. He then

fitted out a squadron at his own expense, with which he prevented the Spaniards from entering Bordeaux, then the stronghold of the rebellious princes. This act of patriotism and daring was rewarded by his promotion to the rank of commodore, while he received as an indemnity for his outlay the island and the chateau of Indret, near Nantes. He continued his successful operations against the Spaniards until the peace of 1659; then he served against the pirates on the coast of Africa. He was made a naval lieutenant-general in 1667, and in the war against Holland was twice engaged against De Ruyter in 1676 in the Mediterranean, first off Stromboli, and afterward in sight of Mt. Etna. In both engagements the Dutch were defeated, and in the latter they lost their commander. A few weeks later Duquesne destroyed the remains of their fleet, and thus for a while secured the supremacy of France upon the sea. Louis XIV. bestowed upon him the estate of Du Bouchet with the title of marquis. He was afterward ordered to clear the Mediterranean of the Barbary pirates; defeated the Tripolitans off the island of Scio in 1681; attempted in 1682 the bombardment of Algiers, which he was obliged to abandon on account of stormy weather; resumed it the next year, and forced the dey to sue for peace. The first condition imposed by Duquesne was the liberation of a considerable number of Christian slaves, and the last the sending of an embassy to Versailles to implore pardon from Louis XIV. In 1684 Duquesne led a successful expedition against Genoa, and soon after retired to his native city.

DURAM, or Durão, Jozé de Santa Rita, a Brazilian poet, born near Mariana in the province of Minas Geraes in 1737, died in Lisbon in 1783. He qualified himself for the service of the church by his studies at Rio Janeiro and at Coimbra in Portugal, was graduated doctor of divinity at the university of the latter city, and joined the religious order of St. Augustine. In the course of his travels in Spain and Italy he became acquainted with Alfieri and other eminent men of letters, and subsequently during his residence at Coimbra composed a poem founded upon the story of the Galician adventurer Diogo Alvarez Correa, surnamed Caramuru, the legendary hero of Bahia. This poem was published at Lisbon in 1781, under the title of *Caramuru, poema epico do descobrimento da Bahia*, and a French version appeared at Paris in 1829. On its first appearance the poem was not highly estimated, but since then it has risen to the rank of a national epic in Brazil.

DURAN, Agustin, a Spanish scholar, born in Madrid about 1793. He received a university education with a view of embracing the profession of the law, but a handsome fortune which fell to his lot permitted him to devote himself to letters. He paid much attention to the study of foreign, especially to French literature, and in 1828 published anonymously a pamphlet on the influence which modern criticism has exercised on the decline of the ancient Spanish drama. He has edited a very important collection of Moorish, miscellaneous, and historical ballads, and ballads of chivalry (Madrid, 1828–'32; republished in Paris in 1838, and in Barcelona in 1840; a new edition, forming part of the extensive *Biblioteca de autores Españoles*, Madrid, 1849–'51). He has also written a history of the Spanish drama from its origin to the middle of the 18th century, which is not yet published.

DURAND, Asher Brown, an American painter and engraver, born in Jefferson, N. J., Aug. 21, 1796. His paternal ancestors were French Protestants, who emigrated to America after the revocation of the edict of Nantes. From early childhood he manifested a taste for drawing, and was fond of studying and copying trees, foliage, and other attractive objects of nature. His art education, however, properly commenced in the shop of his father, a skilful watchmaker, where he learned to cut ciphers on spoons and other household implements, and, chiefly by his own efforts, acquired some knowledge of the elementary processes of engraving. His first attempts at the production of prints were made with plates hammered out of copper coins, and with tools of his own construction, his models being the cards inserted in the cases of watches. A French gentleman, struck with the talent which some of these evinced, employed him to copy a portrait painted on the lid of a snuff box, and the success with which this commission was executed encouraged him to make engraving his profession. In 1812 he was apprenticed to Peter Maverick, one of the most prominent engravers of the time, with whom, after the expiration of his term in 1817, he entered into partnership. For a long time his employment consisted in copying prints from English books, and working on plates for bank notes. His engraving of Trumbull's "Declaration of Independence," the first work which he attempted on a large scale, and which cost him 3 years' labor, brought him into general notice, and thenceforth for many years his graver was in constant demand for portraits of various dimensions, and figure pieces. Of the former, the "National Portrait Gallery" affords the best example, while his "Musidora" and "Ariadne," the latter engraved from Vanderlyn's picture, are among the most creditable specimens of the art produced in this country. He had always, however, entertained the idea of ultimately becoming a painter, and in 1835, having for the previous 10 years been a regular contributor of portraits, small figure pieces, or landscapes in oil, to the exhibitions of the national academy of design, he finally abandoned engraving as a profession. For several years afterward he painted principally portraits and landscapes, and occasionally figure pieces, a class of subjects to which he would willingly have devoted himself had the opportunities for studying from life or from models been sufficiently abundant. As landscape painting, however, accorded with his early tastes, and was

not liable to this objection, he soon began to give his exclusive attention to it, and for many years has been an industrious contributor to this department of his art. From the outset he has been a close student of nature, giving great attention to the forms of trees, the different species of which he carefully distinguishes in his pictures, and elaborating the objects of a landscape with scrupulous exactness. His pictures, embracing some of the finest mountain and valley scenery in the country, are eminently pleasing and true in color and tone, and frequently have an idyllic beauty characteristic of the artist's turn of mind. Those representing woodland scenes are conceived with much poetic feeling, and present fine studies of trees and foliage. His collected works, many of which are of large dimensions, and some of which have been engraved, would convey an unusually correct idea of American scenery under many different aspects. Of his figure pieces, which are the rarest of his works, the principal are "Harvey Birch and Washington;" "An Old Man's Reminiscences;" "The Wrath of Peter Stuyvesant;" "God's Judgment on Gog;" "The Dance on the Battery;" "The Capture of Major André," &c. Among his earlier landscapes may be enumerated: "The Morning and Evening of Life," a pair; "Lake Scene—Sunset;" "The Rainbow;" "Wood Scene," &c. During the last few years he has produced "Primeval Forest" (1853); "In the Woods" (1854); "The Symbol," from Goldsmith's "Deserted Village" (1856); "Franconia Mountains" (1858); and "Reminiscences of Catskill Cloves" (1859). In 1854 he painted a portrait of William C. Bryant, the engraving from which, published in 1858, received its finishing touches from his hand. Mr. Durand is one of the few remaining original members of the national academy of design, and upon the resignation of Prof. Morse was chosen the president, a position which he still holds. He has resided in New York during the greater part of his life.—His son, John Durand, has for several years conducted the "Crayon," a monthly publication specially devoted to the interests of the fine arts.

DURANGO, an inland state or department of Mexico, 280 m. long from N. to S., and 150 m. broad; area, 48,489 sq. m.; pop. in 1851, 162,218. It was formerly sometimes called New Biscay. The surface is rocky and mountainous, being traversed by the Sierra Madre, which unites the plateau of Anahuac with the Rocky mountains. There are a few small streams, the principal of which is the Rio de las Nases, but no large rivers. In the valleys of these streams are some fertile and well cultivated tracts, producing good crops of rice, maize, and corn, but the general character of the soil is barren and incapable of much improvement. There are some pasture lands, however, and considerable numbers of cattle are reared. The mountains furnish gold, silver, and iron, which are extensively and profitably mined. This department is subject to frequent inroads of the Comanches and other Indian tribes, who overrun the country at certain seasons, pillage the settlements, drive off the cattle, and massacre all who come in their way.—Durango, or Victoria, the capital of the state, is situated on an elevated plain at the foot of the Sierra Madre, 7,295 feet above the level of the sea; pop. in 1853, about 8,000. It is the see of a bishop, contains several good buildings, and enjoys an extensive trade in cattle and leather. It is in the vicinity of iron mines, and has a mint. The general appearance of the town is picturesque, but it is excessively dirty, infested by scorpions, and has, of late years, rapidly declined in population. It was founded in 1551.

DURÁZZO (anc. *Epidamnus* or *Dyrrachium;* Turkish, *Dratch;* Alb. *Duraessi*), a maritime town of European Turkey, in the province of Albania, on the E. coast of the Adriatic, 50 m. S. W. of Scutari; pop. about 7,000. It is strongly fortified, has a safe and commodious harbor, and carries on a considerable trade in corn, tobacco, and British manufactured goods, which are imported from Trieste. It occupies the site of the ancient Epidamnus, which was founded by a colony of Corcyreans and Corinthians in the 7th century B. C. The feuds of its nobles and people were one of the immediate causes of the Peloponnesian war. In the Roman times it became one of the chief points of communication between Italy and the East. During the civil war of Pompey and Cæsar it was occupied by the former, who obtained in its vicinity a victory over the forces of his antagonist. In the 11th century it was captured by the Normans, and subsequently by the Venetians, from whom it was taken by the Turks about the end of the 15th century.

DURBIN, John Price, D.D., an American clergyman, born in Bourbon co., Ky., in 1800. After receiving the elements of education in a district school, he entered the ministry of the Methodist Episcopal church in 1819, was sent to Limestone circuit, Ky., and the next year was received into the Ohio conference and stationed on Greenville circuit, Ohio. He availed himself of every opportunity for study, and with his grammar and commentary, by the light of pine knots in the log cabins of the wilderness, he spent his evenings in mastering their contents. He was soon after stationed in Hamilton, O., 12 miles from Oxford, the seat of the Miami university. He entered this institution, pursuing his studies from Monday until Saturday, when he would attend to his duties as pastor, and then return to his studies in college. While stationed subsequently in Cincinnati he was admitted to the Cincinnati college, where he received the degree of A.B. in 1825, and subsequently that of A.M. Soon after this he was elected professor of languages in Augusta college, Ky. In 1829 he was nominated as chaplain to the senate of the United States, and only failed of election by the casting vote of Mr. Calhoun, which that distinguished statesman afterward regretted. His friends, without his

knowledge, again secured his nomination in 1831, and he was elected by a large majority. His sermon in the capitol on the centennial anniversary of Washington's birth was one of his most successful efforts. In 1832 he was elected professor of natural science in the Wesleyan university, and in 1833 was appointed by the general conference editor of the "Christian Advocate and Journal," New York. The following year he was elected president of Dickinson college, Penn., where he continued until 1842. He then made a journey through portions of the old world, and returning the next year, published "Observations in Europe, principally in France and Great Britain" (2 vols. 12mo., New York, 1844), and "Observations in Egypt, Palestine, Syria, and Asia Minor" (2 vols. 12mo., New York, 1845), which had a large sale. He was a member of the general conference of 1844, and took an important part in the debate which resulted in the division of the Methodist Episcopal church. In 1845 he resigned the presidency of the college, and was stationed in Philadelphia as presiding elder. In 1850 he was elected corresponding secretary of the missionary society of the Methodist Episcopal church, which post he occupies at the present time.

DUREAU DE LA MALLE, Adolphe Jules César Auguste, a French author, born March 2, 1777, died May 18, 1857. Under the auspices of his father, Jean Baptiste Joseph René, the translator of Tacitus and Sallust (born 1742, died 1807), he received an excellent education. He first wrote poetry and afterward on archæology, geography, political economy, and climatology. His most important work, *Économie politique des Romains*, appeared at Paris in 1840.

DÜRER, Albrecht, a German painter and engraver, born in Nuremberg, May 20, 1471, died there, April 6, 1528. His father, a skilful goldsmith, wished him to follow the same profession; but yielding to his son's inclination to become an artist, he placed him, when 15 years of age, with Michael Wohlgemuth, the leading painter of Nuremberg. With him Albrecht remained 4 years, after which he travelled through Germany and the Low Countries, employing several years in the study not merely of his own art but of many of the most important collateral branches. In 1494 he established himself permanently in Nuremberg, and shortly after, at the solicitation of his father, married the daughter of Hans Fritz, an artisan of that place. The union was not a happy one, as the shrewish temper of his wife sorely taxed the equanimity of the painter, and it is even said shortened his life. During his apprenticeship to Wohlgemuth, and his absence from Nuremberg, he had painted and engraved on wood, although nothing is known with certainty of his youthful works. The earliest well authenticated picture by him bears the date of 1498, and is a portrait of himself. Another similar portrait, dated 1500, and now in the Pinakothek at Munich, gives a vivid impression of the artist. It represents a man in the prime of life, in whose noble features and earnest eye are seen the evidences of a reflective mind. He stands in a dignified attitude, and his hair falls in beautiful profusion over his shoulders. In his last portrait, a woodcut of the year 1527, the face is marked by lines of care, and the head is shorn of the flowing locks in which the artist was wont to take a complacent pride. In 1498 appeared his first great series of woodcuts, illustrating the Revelation of St. John; a work of singular power, in which the artist's imagination, however, is controlled by the fantastic element which then pervaded German art. Throughout the series the wonderful and monstrous meet in living bodily forms. In 1506, by the aid of his friend Wilibald Pirkheimer, Dürer made a journey to northern Italy, and remained a considerable time at Venice, Bologna, and other places, for the purpose of improving himself in his art; but so firmly was he grounded in his peculiar style, that the graceful productions of the Italian schools had no influence upon him. From the time of his return to Nuremberg, in 1507, ensued a period of singular artistic activity, and among the great works which he then produced may be enumerated the paintings of the "Martyrdom of the 10,000 Saints," at Vienna; the "Assumption of the Virgin," burned at Munich; the "Adoration of the Trinity," at Vienna; "Christ taken from the Cross," at Nuremberg; and the "Adoration of the Magi," at Florence; the woodcut series of the "Greater" and "Lesser Passion," the "Life of the Virgin," the "Triumphal Arch of the Emperor Maximilian," &c.; the copperplate engravings of "The Knight, Death, and the Devil," "Melancholy," "St. Jerome;" and portraits of his friends Pirkheimer, Melanchthon, and Erasmus. The print of "The Knight, Death, and the Devil" suggested to Fouqué his tale of "Sintram and his Companions." It is supposed by Bartsch and others that the woodcuts which pass under Dürer's name were cut by engravers from his drawings on the wood. His career was prosperous, and he enjoyed the friendship of many of the most learned men of the day, to whom his cultivation of letters no less than his artistic genius commended him. The people of Nuremberg delighted to honor their great painter, who was for many years one of the chief burghers of his native town. The emperors Maximilian I. and Charles V. successively appointed him court painter, and the chief cities of Germany were emulous for the possession of his works. In 1520 Dürer made a second journey to the Netherlands, and showed that he was not too old to labor, and be instructed in his art. Melanchthon tells us that Dürer confessed to him that his previous works fell short of his present conception of the beauty of nature, and that he regretted bitterly that he had painted so many pictures void of that simplicity which is the greatest charm of art. Under the influence of this visit his subsequent works exhibit a soberer feeling, and a refinement of that exuberant fancy in which he formerly delighted. In 1526 were produced his 2 pictures containing figures of the size of life of the apostles John and Peter, Mark

and Paul, which were among his last, as they are generally esteemed his grandest works, and which he presented to the council of his native city. Dürer had at this time embraced the doctrines of the reformation, and these paintings, the fruit of earnest reflection and of deep religious conviction, are supposed to have conveyed the artist's exhortation to his countrymen to stand firm in the new faith. In dignity and sublimity of composition, and in richness of color, they are masterpieces of art.—As an engraver and a painter Dürer was one of the most remarkable men of an age prolific of great artists. In grandeur of conception and invention he was in fact before the age. His rich and inexhaustible spirit grasped at many things. In painting, he raised German art to an excellence which passed away with him; he found engraving in its infancy, and carried it to a perfection never since surpassed; he cultivated architecture and sculpture, and as a theorist wrote valuable treatises on geometry and fortification, with a purity of style evincing a profound knowledge of the German language. He was the first German artist who taught the rules of perspective, and insisted on the study of anatomy. His works exhibit a deep sense of the sublime and solemn, as also of simple grace and tenderness, and a feeling for art such as could only have inspired a great master. Above all, his imagination seemed boundless. But the tendency to the fantastic, a striking attribute of old German art, obstructed the pure development of his power as an artist. This tendency, which has been ascribed to the peculiar physical aspects of northern nature, and of which we have illustrations in the wild legends and the grotesque ornamentation of the architecture of mediæval Germany, seems to have culminated in that age; and with his countrymen Dürer felt its influence, and reflected it in his works. Independence of thought in matters of religious belief necessarily suggested a greater freedom of imagination, and he rejected the classic ideal which Raphael and his contemporaries had so successfully realized, to wander in the realms of fancy. Hence his strange attitudes, his fanciful draperies, his over-elaborate costumes and accessories, and the Gothic element, so to speak, which seems to pervade all his works. His wonderful creations, nevertheless, surprised and delighted the Italians, and Vasari confesses that he would have been an extraordinary artist had he enjoyed an Italian instead of a German education. Raphael had the highest admiration of his genius, and sent him a drawing executed by his own hand. In so great estimation were his prints held, that the engraver Marc Antonio Raimondi was induced to execute at Venice a set of the "Passion" and the "Life of the Virgin," with facsimiles of Dürer's monogram attached, which were sold as originals. The artist was obliged to visit Venice to obtain redress. The memory of Dürer is held in great veneration by the people of Nuremberg, who preserve the house in which he lived with religious care. On the 300th anniversary of his birth the corner stone of a monument to his memory was laid in Nuremberg; and in May, 1840, the work was completed by the addition of a bronze statue of the artist by Rauch.

DURESS (law Lat. *durities*, Fr. *duresse*). Constraint, either by actual violence or the threat of some injury, is in law an excuse for many acts which would otherwise be criminal; so it is also a ground for avoiding conveyances, contracts, and other civil acts which have been compelled by such violence or threat. A distinction is however made as to the nature and extent of the duress, in the two classes of cases above referred to. When set up as an excuse for a criminal act, it is subject to several qualifications. 1. It cannot in general be admitted in justification of a capital offence, but only for lesser crimes, called misdemeanors. This limitation applies only when innocent parties are involved, for a man has the right to kill an assailant who puts him in peril of life or of grievous bodily injury. 2. The apprehension of danger must be such as might be reasonably entertained by a person of ordinary courage; *talis qui cadere possit in virum constantem, non timidum et meticulosum.* 3. The injury which is threatened must be such as to endanger loss of life or limb. Fear of assault and battery merely would not justify, according to the old cases, even a misdemeanor. 4. Command by a father or master is not a justification to a child or servant for the commission of a crime, yet the wife was by the common law held to be in the power of the husband so far that what was done by her in his presence was deemed to be done under duress, and was a justification even for capital offences, except treason and murder. This was upon the legal presumption that if the husband was present, the wife acted by his coercion; still greater would be her claim to exemption if actual coercion could be proved. There was, however, a singular inconsistency in not allowing the same excuse on the ground of coercion, actual or presumed, in respect to mere misdemeanors. It has been plausibly suggested that the reason of this anomaly was that the wife was not entitled to the benefit of clergy, while the husband was so entitled; and as he could therefore escape from punishment for certain offences, but the wife was subject to the penalty, the law humanely interposed and relieved her from all legal liability in cases where husband and wife were jointly chargeable, but in which a claim to benefit of clergy was allowed, and this privilege did not apply to misdemeanors, nor to murder or treason. 5. Duress of imprisonment, by which is meant illegal arrest or deprivation of liberty, is referred to in the English cases only as a ground of avoiding contracts; but upon the principle asserted by the common law that a man's liberty is as sacred as the security of life, any interference therewith, unless by process of law, should be held a justification for any degree of force necessary to resist an unlawful restraint of liberty; and by

analogy to other cases of duress, actual imprisonment, or menace of imprisonment, should also be an excuse to some extent, even if not a full justification, for offences which would be excused by fear of bodily injury. On the other hand, it may be said that wrongful imprisonment is not a permanent injury, like bodily mutilation, and can be compensated in damages. Resistance to an unlawful attempt to deprive a man of liberty would, however, it may be presumed, be justified, even to the extent of taking the life of the wrong doer, if that were necessary; but neither actual nor threatened imprisonment will justify the commission of a criminal offence affecting any other person.—Duress in relation to contracts or other civil acts, is not limited to bodily injury or loss of personal liberty, but may be founded upon apprehension of damage in respect to property. The apprehended injury must, however, be something extraordinary, and which does not admit of exact pecuniary indemnity; but great allowance will be made for the effect of any threatened loss in the disturbance of a man's judgment and self-possession, and probably in our courts a contract would be held void which had been procured by the menace of any considerable damage when made suddenly, and time not allowed for reflection. Bacon mentions the perturbation of mind as a reason why coercion, or what he calls necessity, "carrieth a privilege" as respects crime (Bacon's "Maxims," *regula* 5); and the reason ought to have equal force in avoidance of a contract. The rule as stated by Blackstone is much narrower, and excludes not only damage to property, but even personal injury, except what involves danger to life or limb. A fear of battery, therefore, or of having one's house burned, or goods taken away, he says, is no duress, because in these cases there can be pecuniary compensation. But he does not seem to have sufficiently observed the distinction between duress as an excuse for a criminal offence and duress as a ground of avoiding a contract. Bacon with more discrimination states the rule in the latter case that restraint of a man's person, or threat of a battery, or of burning his house, is a duress which will avoid a bond given under such restraint or menace. In the courts of the United States the rule has been extended to pecuniary loss affecting personal property. This at least has been decided in the states of South Carolina and New York. (See 1 Bray's Rep. 470; 2 id. 211; 5 Hill, N. Y., 154.)

DURFEE, Job, an American author and jurist, born in Tiverton, R. I., Sept. 20, 1790, died there, July 26, 1847. He was graduated at Brown university in 1813, afterward studied law, was elected to the state legislature in 1814, and in 1820 was chosen representative in congress, where he served during 2 terms. He was a member of the state legislature again in 1826, and in 1833 was appointed associate justice of the supreme court of Rhode Island. In 1835 he became chief justice, an office which he held until his death. In 1832 he published a poem in 9 cantos, entitled "Whatcheer," being an account of the departure of Roger Williams from Salem, his adventures in the wilderness, and the settlement of Rhode Island. He also wrote a philosophical treatise called "Panidea," to prove the pervading influence and presence of God throughout nature. His works were collected and published with a memoir by his son (8vo., Providence, 1849).

D'URFEY, Thomas, a humorous English poet, died at an advanced age, Feb. 26, 1723. He was of a French Protestant family which had fled from La Rochelle in 1628, when it was besieged by Louis XIII., and had settled in Exeter, where the poet was born. Abandoning the profession of law for the more congenial pursuits of literature, he wrote ballads, sonnets, irregular odes, and more than 30 pieces for the theatre. His dramatic pieces were very successful; but as they are written in the licentious style prevalent after the restoration, they are not now represented upon the stage. His works show the character of the author, who was sufficiently amusing to count among his patrons King Charles II., Queen Anne, and even the stern and sombre William III. Steele and Addison in the "Guardian" befriended him, and solicited the attendance of their readers to a play for his benefit. His best known work, beside his plays, was a collection of songs and ballads, partly by himself, entitled "Wit and Mirth, or Pills to purge Melancholy" (6 vols. 12mo., London, 1719–'20).

DURHAM, a maritime co. in the N. of England; area, 973 sq. m.; pop. in 1851, 390,997. The general aspect of the county is mountainous, particularly in the western part, where it is traversed by branches of that range of hills to which the name of the English Apennines has been applied. From these several ridges shoot off in different directions, and some of them, projecting as far as the sea, terminate in tall cliffs and headlands. Numerous rivers rising among the mountains in the west flow through the valleys and empty into the ocean. Among these are the Tyne, the Tees, and the Wear, all of which are navigable for a considerable part of their course, and have important towns and tolerable harbors at their mouths. The valley of the Tees, particularly near its estuary, has a great deal of rich alluvial soil, under careful cultivation, or devoted to pasturage. It is here that the Durham cattle, so famous for their many excellent qualities, are most extensively reared. The Teesdale sheep, noted for their unusual size and tender flesh, are scarcely less celebrated than the Durham cattle, and are more highly prized than any other English breed. In the bleak table-lands of the western part, where cultivation is not attempted, are found rich veins of lead, and east of this region occurs the most extensive coal field of Great Britain, known as the Newcastle coal region. In addition to these important productions, iron, firestone, and millstones are found in large quantities. Limestone, some of it of a peculiar excellence, underlies an exten-

sive portion of the county. The value of all these products is vastly increased by the facilities of transportation from the mining district to the seaboard. Beside the navigable rivers, there are many railways traversing the county and connecting the great coal region with the coast, with Scotland, and with some of the most important towns of England. The principal manufactures are iron work, pottery, glass, coal tar, salt, linen, and woollen. Durham is deficient in timber, and with the exception of the groves attached to country seats of the nobility, and some portions of the vale of Derwent, there is little woodland of any value. Durham, Chester, and Lancaster were formerly counties palatine, so called because the bishop of Durham, the earl of Chester, and the duke of Lancaster had royal rights in their respective territories as fully as the king in his palace. The jurisdiction of the bishop of Durham was transferred to the crown in the reign of William IV. The county consists politically of 2 divisions, each of which sends 2 members to the house of commons.—DURHAM (anc. *Dunelmia*, *Dunelmum*, *Dunholmum*, *Dunholme*), the capital of the county, is an ancient episcopal city and parliamentary borough, built on 7 small hills, and nearly encompassed by the river Wear, which is here crossed by several bridges; pop. in 1851, 13,188. Its external appearance is at once attractive and imposing. The river banks are skirted by plantations, hanging gardens, and beautiful public walks, beyond which the houses rise one above another, until they are crowned by the grand cathedral and an ancient Norman castle, which occupy the summit of a rocky eminence. The city consists of several divisions, of which the one situated between the cathedral and the river has many elegant residences. The old town, which lies N. of the castle, contains most of the shops, and a market place with a fountain. There are suburbs on each side of the river, some of which are occupied chiefly by the poorer classes. Among the public buildings and institutions are a town hall, built in the Tudor baronial style, a great number of schools, an infirmary, hospitals, reading rooms, libraries, assembly rooms, a theatre, 6 parish churches, various chapels, and a university. A college was founded here as early as 1290 by the prior and convent of Durham, which was afterward enlarged, and under Henry VIII. was transferred with all its endowments to the dean and chapter. Under Cromwell the funds were employed by a new corporation, but on the restoration they reverted to the former trustees. The present university owes its foundation mainly to Dr. Charles Thorp, archdeacon of Durham. It was opened to students in 1833, and incorporated in 1837. Bishop Hatfield's hall was instituted in 1846 for divinity students. The most interesting edifice in Durham is the cathedral, founded in 1093 by King Malcolm and Bishop Carilepho. Its length, including the western porch, is 507 feet, its greatest breadth 200 feet, and it has a central tower 214 feet high, beside 2 low towers, once surmounted by spires. The predominant style of architecture is the early Norman, but in the various additions made to the church from time to time, we have specimens of the different styles which had prevailed in England up to the close of the 14th century. The Galilee chapel at its W. end, built by Bishop Pudsey between 1153 and 1195, contains the remains of the venerable Bede; those of St. Cuthbert, the patron of the church, rest in the chapel of the nine altars. The old church of St. Nicholas was partly repaired and partly rebuilt in 1858, and is now considered one of the finest specimens of modern church architecture in the N. of England. There is a school house attached to it. Immediately opposite the cathedral stands the castle, founded by William the Conqueror for the twofold purpose of maintaining the royal authority in the adjoining districts and protecting the country from the inroads of the Scots. Many additions have been made to it, and it is doubtful whether any part of the original keep, except the foundation, now remains. For many years it was the residence of the bishop of the palatinate, but of late it has been given up to the uses of the university. The see of Durham was long the richest in England, and for the 3 years ending with 1831, the average annual net revenue of the bishop was £19,066; but in 1836 his income was fixed at £8,000, the surplus revenue being applied to the augmentation of the incomes of poorer bishops. Prior to the opening of the collieries, and the construction of the numerous railways which now intersect the county, Durham made little progress, but the activity awakened by these great works has given a powerful impetus to its trade and population. It has manufactories of carpeting and mustard. In the vicinity are Neville's Cross, erected by Lord Neville in commemoration of the defeat of David II. of Scotland, in 1346, and the site of an old Roman fortress, called the Maiden castle. The town sends 2 members to the house of commons.

DURHAM, JOHN GEORGE LAMBTON, earl of, an English statesman, born in Durham, April 12, 1792, died in the isle of Wight, July 28, 1840. He was educated at Eton, served a short time in a regiment of hussars, married at the age of 20, and had hardly attained his majority when he was returned to parliament for his native county. His first speech, delivered in 1814, was an unsuccessful appeal in behalf of the people of Norway struggling under Prince Christian of Denmark for their national independence, in opposition to the stipulations of the allies at Kiel. The next year he introduced a motion in behalf of Genoa, to which the reëstablishment of its ancient constitution had been promised by Lord Bentinck in the name of England, but which was by the stipulations of the congress of Vienna annexed to the kingdom of Sardinia. When the Castlereagh ministry in 1816 proposed to add more rigorous conditions to the alien act, he opposed the measure with great energy. During the chartist excitement of 1819, he vindicated the rights

of the people, not only in parliament, but in numerous public meetings. He was one of the defenders of Queen Caroline in 1821, and seconded Lord Tavistock's motion of censure on the ministry for their proceedings against her. The same year he promulgated a scheme of parliamentary reform, and though his bill was rejected by a manœuvre before discussion, yet 10 years later he saw his ideas revived in the celebrated reform act, in the passage of which he then assisted as a member of the cabinet. In 1826 the feebleness of his health obliged him to relax his labors, and he passed a year in Naples, and on his return to England was raised by Lord Goderich to the peerage, under the title of Baron Durham. Upon the formation of the ministry of his father-in-law, Lord Grey, in 1830, he was called into the cabinet as lord privy seal. This administration was formed upon the basis of making parliamentary reform a cabinet question, and the preparation of the plan of reform was intrusted to Lord Durham, Lord John Russell, Sir James Graham, and Lord Duncannon. To Lord Durham fell the task of defending the bill in the house of lords, a difficult labor, since he had to contend not only against the open opposition of the tories, but against the secret repugnance of many of his colleagues and political associates. His health suffered a heavy shock at this time by the death of his eldest son, and though he afterward spoke a few times upon the 2d and 3d bills, he retired from the administration in 1833, and was raised to an earldom. He was sent the same year upon a special mission to Russia; but he was unsuccessful in his main object, which was to induce the Russian government to mitigate its severity toward the Poles, who had lately made an unsuccessful attempt to recover their independence. Returning to England, his liberal views brought him into collision with the existing government. His separation from his former colleagues was clearly manifested in remarks which he made at a public dinner given to Lord Grey at Edinburgh, which caused him to be generally regarded as the leader of the movement party. The insurrection in Canada in 1837 and the following years opened a new field to his activity, and in 1838 he was sent thither as governor with extraordinary powers, the ministry hoping that his liberality of sentiment and large political experience would secure the confidence of the people. Yet his administration there was brief. Trying at once to conciliate and to punish, he gained only the ill will of the Canadians; and surpassing his powers by transporting the leaders of the rebellion for an indefinite time to Bermuda, a disapproval of his conduct was voted by parliament. Lord Durham complained that he was not vigorously supported by the ministry, resigned his office, and suddenly returned to England. He prepared an elaborate report on Canadian affairs, setting forth liberal principles of colonial government, and proposing the union of the two provinces, which has had much influence on British colonial administration. His policy and plans were adopted by his successor, and vindicated by himself in the house of lords. His political views giving him an almost solitary position, and being unable by reason of feeble health, under which he had long suffered, to sustain alone a struggle in parliament, he afterward took but little part in public affairs.

DÜRINGSFELD, Ida von, a German authoress, born in Lower Silesia, Nov. 12, 1815, married in 1845 Baron Reinsberg, visited Italy and Switzerland, and wrote interesting sketches of her travels (*Reiseskizzen*, vol. i., Switzerland, 1850; vol. ii., Italy, 1857; vol. iii., Carinthia, 1857; vols. iv. and v., Dalmatia, 1857), and a series of sketches of high life, or *Skizzen aus der vornehmen Welt* (6 vols., 1842–'45). The most recent of her numerous works are *Esther* (Breslau, 1851), and *Clotilde* (Berlin, 1855). She has also written poetry and songs, and translated Bohemian national songs into German (*Böhmische Rosen*, Breslau, 1851). Several of her original songs were set to music, and her *Lieder aus Toscana* appeared in Dresden in 1855.

DUROC, Gérard Christophe Michel, duke of Friuli, a French general, born in Pont-à-Mousson, near Nancy, Oct. 25, 1772, killed near Markersdorf, in the vicinity of Görlitz, Prussia, May 23, 1813. After having served in the first wars of the revolution as adjutant of Gen. L'Espinasse, he joined the army of Italy in 1796, became brigadier-general in 1797, took part in the Egyptian campaign, and after Napoleon's return to France and the 18th Brumaire, in which he was a chief actor, he was made lieutenant-general and governor of the Tuileries. Subsequently he was employed on diplomatic missions in Stockholm, Copenhagen, St. Petersburg, Berlin, and Dresden; took part in 1805 in the battle of Austerlitz as successor of Gen. Oudinot, who had been wounded; and accompanied Napoleon in his campaigns in 1806 and 1807. In 1809 he was with the emperor in Austria, and negotiated the truce of Znaym. In 1812 he was in the Russian campaign, always enthusiastically devoted to the cause of Napoleon, of whom he was a great favorite. After the battle of Bautzen, while escorting the emperor to an adjoining elevation for the purpose of inspecting the battle ground, he was killed by a cannon shot. The farm house in which he died the same evening was purchased by Napoleon, who caused a monument to be erected there to Duroc's memory. His remains were interred in 1845 in the church of the Invalides in Paris.

DÜRRENSTEIN, a town of Lower Austria, on the Danube, 41 m. W. by N. from Vienna, belonging to the princely house of Starhemberg; pop. 500. It is famous for its ruins of the old castle in which Richard Cœur de Lion, while returning from his crusade in Palestine in 1193, was kept a prisoner during 15 months by Duke Leopold of Austria. The castle is seen on a naked and lofty rock back of the village, on the border of the dark heights of the Wunderberg. Here on Nov. 11, 1805, the French un-

der Mortier defeated the Austrians and Russians under Kutusoff.

DÜSSELTHAL, formerly a convent of Trappists between Düsseldorf and Elberfeld; at present an educational institution, established in 1821 by a Prussian nobleman for the benefit of helpless children, and of converted Jews who wish to become mechanics or farmers.

DÜSSELDORF, a district of Rhenish Prussia, bounded N. and W. by Holland, and traversed by the Rhine; area, 2,096 sq. m.; pop. in 1855, 1,017,500. The 14 circles of the district include the circle of Düsseldorf (pop. in 1855, 85,560), and the most celebrated manufacturing towns of the country, as Elberfeld, Crefeld, Solingen, Lennep, &c. The industrial interests absorb the best energies of the inhabitants, and agricultural pursuits are comparatively neglected. On the left shore of the Rhine, however, the richness of the soil is great, and the trade in cereals and cattle is not inconsiderable, although a more steady attention to the resources of husbandry might enhance its importance. The district abounds in mineral wealth, especially in coal and iron.—DÜSSELDORF, the capital of the district and circle of the same name, is situated at the confluence of the Düssel with the Rhine, 22 m. by railway N. from Cologne; pop. in 1855, 45,000. As a great focus of railway and steamboat communication, a fair proportion of the transit trade of the Rhine is carried on by the merchants of Düsseldorf. The manufacturing interest is not as fully represented as in Elberfeld and other neighboring towns, but there are many carriage, tapestry, cotton, tobacco, and mustard manufactories, tanneries, and dyeing establishments. In 1288 Düsseldorf became a municipality. In modern times it has been successively under the dominion of Brandenburg and Neuburg, under French and Bavarian rule, and was for some time the capital of the duchy of Berg, until in 1815 it passed with the whole duchy under the sway of Prussia. It is divided into 4 sections, the Altstadt, the Karlstadt, the Friedrichsstadt, and the Neustadt. The last was laid out by Johann Wilhelm, the elector palatine, whose statue adorns the market square and the palace yard. The Karlstadt is the most modern part of the town, and derives its name from Karl Theodor, its founder, the same public-spirited prince who established in 1767 the academy of painting. The town possesses many delightful parks or gardens, and the *Hofgarten* is one of the finest in Prussia. New and beautiful streets have been laid out within the last 15 years in the southern and eastern portions of the town. The prominent public buildings are the governor's palace, the town hall, the cabinet of antiquities and that of scientific instruments, the tribunals, the observatory, which occupies the former collegiate buildings of the Jesuits, the St. Andreas church, which also belonged to the Jesuits in former times, and the church of St. Lambert. Both churches contain monuments of the ancient sovereign princes of Düsseldorf. There are numerous charitable and literary associations, a gymnasium, a primary school, a polytechnic institute, an academy of commerce, and a good theatre. The celebrated picture gallery, which was established here in 1690, and which contained superb specimens of the best Flemish and Dutch masters, was transferred to Munich in 1805. The collection of 14,000 original drawings and 24,000 engravings and casts, however, which formed part of the same gallery, still remains in Düsseldorf, and received in 1841 an addition of 300 water-color drawings after Italian masters. Art has flourished here more than in any other German town, especially since 1822, when Frederic William III. renovated the building of the academy, and when at the same time Cornelius, Schadow, and other artists of genius arose to give a powerful impulse to art generally, by laying the foundation of the Düsseldorf school of painters. The art union for Rhenish Prussia and Westphalia was founded here in 1828. The engravers' establishment of the royal academy of Schulgen-Bettendorf was removed from Bonn to Düsseldorf in 1837. Beside the academy of painting, there is a school for painters and one for architects. The average annual attendance of art students at the various institutions is about 400. There are 2 political and several literary and humorous papers and magazines published in Düsseldorf. Among the many eminent persons born in the town were Heine the poet, and Cornelius the painter.

DUTCH LANGUAGE AND LITERATURE. See NETHERLANDS.

DUTCHESS, a S. E. co. of N. Y., bounded W. by the Hudson river, and E. by Connecticut; area, 816 sq. m.; pop. in 1855, 60,635. The surface is uneven and in many parts hilly. Fishkill river and Wappinger's creek supply it with good water power, which is employed in a number of mills. Much of the soil is best adapted to grazing, but the cultivated portions are carefully improved and very fertile, yielding large crops of grain and potatoes. The productions in 1855 were 558,308 bushels of Indian corn, 626,347 of oats, 54,720 of wheat, 205,498 of potatoes, 83,878 tons of hay, and 1,681,595 lbs. of butter. There were 39 grist mills, 12 saw mills, 6 cotton and 6 woollen factories, 9 furnaces, 132 churches, 10 newspaper offices, and 206 school houses. Limestone, slate, marble, iron, and lead are the most important minerals. The county has great facilities for communication with New York, Albany, and other parts of the Union, by means of the Hudson river, navigable along its western border, and the Hudson river and Harlem railroads, which intersect it. Capital, Poughkeepsie.

DUTENS, JOSEPH MICHEL, a French political economist, born in Tours, Oct. 15, 1765, died Aug. 6, 1848. He was educated as a civil engineer, and in 1800 published a topographical description of the arrondissement of Louviers (Eure). He first became known as an economist by his *Analyse raisonnée des principes fondamentaux de l'économie politique* (8vo., Paris, 1804). In 1818, being appointed by the French government to examine the system of interior

navigation in England, he enlarged the object of his mission to a careful examination of all the great public works of that country, and published his learned researches during the next year. His most important work was published in 1835 with the title of *Philosophie de l'économie politique, ou nouvelle exposition des principes de cette science* (2 vols. 8vo.), which opened a lively discussion between him and the disciples of Adam Smith. He published another work in defence of his later principles of economy, in which, in accordance with the school of Quesnay and Turgot, he maintains that commercial and manufacturing industry does not give a net product, and that this advantage can be predicated only of agricultural labor.

DUTROCHET, René Joachim Henri, a French physiologist, born in Néon, Nov. 14, 1776, died Feb. 4, 1847. His family was rich and noble; but their property having been confiscated during the revolution, he studied medicine in Paris, and served in the army as physician in the Spanish campaigns of 1808 and 1809. He published researches upon the formation of the egg in birds and fowls, upon the gradual unfolding of the allantois in the incubated egg, upon the increase of the young as the albumen diminishes, upon the structure and growth of feathers, upon the envelopes of the fœtus of mammalia and of the human fœtus, and upon the growth of vegetables and insects. His most important works were collected in 1837 under the title of *Mémoires pour servir à l'histoire anatomique et physiologique des végétaux et des animaux;* and in 1842 he published *Recherches physiques sur la force épiploique.*

DUUMVIRS, among the ancient Romans, two officers appointed temporarily and for a particular purpose. They were therefore of various sorts, and were specially named from the nature of their functions. The *duumviri juri dicundo* were the highest magistrates of colonies and towns, where they had the rank of consuls at Rome. The *duumviri navales* had charge of the construction and equipping, and sometimes of the command of fleets. The *duumviri quinquennales* were the censors of municipal towns. The *duumviri sacrorum* had originally the charge of the Sibylline books. The *duumviri ludorum* in the Byzantine empire were functionaries elected to the burdensome office of exhibiting games at their own expense to the people for one year.

DUVAL, a N. E. co. of Fla., bordering on the Atlantic, and bounded by St. John's river on the E. and Nassau river on the N.; area, 430 sq. m.; pop. in 1850, 4,539, of whom 2,106 were slaves. The surface is generally level, and the soil adapted to sugar, cotton, Indian corn, and sweet potatoes. In 1850 it produced 391 hhds. of sugar, 216 bales of cotton, 51,788 bushels of Indian corn, and 27,674 of sweet potatoes. There were 5 saw mills in the county, 8 churches, and 64 pupils attending public schools. Capital, Jacksonville.

DUVAL, Valentin Jameray, a French scholar, born at Arthonnay, in Champagne, in 1695, died in Vienna, Sept. 13, 1775. After the death of his father, who was a poor peasant of the name of Jameray, young Valentin was charitably taken up by a priest, who stored his mind with piety and learning. Subsequently he was employed as cowherd by 4 ignorant hermits near Lunéville, but took every opportunity to increase his knowledge. He purchased books from the proceeds of the game which he found in the adjoining woods, and his library received an unexpected addition from a present of $30 given to him by an Englishman for having found and restored to him a golden seal which he had lost. He had accumulated about 200 books, when one of the hermits, exasperated at his neglecting the cows for his reading, threatened to burn his library. The young man, enraged, drove the hermit from his cell, barred the door, and would not capitulate until his employers agreed to allow him two hours a day for study; in consideration of which he bound himself to serve them 10 years longer, with no other wages than his board and clothing. One day while keeping his cows, and surrounded as usual with books and maps, he was found by Leopold of Lorraine, who placed him under the instruction of the Jesuits of Pont-à-Mousson. Here he made rapid progress, and Duke Leopold took him to Paris in 1718. Subsequently he appointed him librarian and professor of history at the noblemen's academy of Lunéville. Among his pupils was William Pitt, afterward earl of Chatham. The income he now received soon enabled him to build a homestead upon the spot of his early solitary haunts. When Lorraine was ceded to France he accompanied Duke Francis, in his old capacity of librarian, to Florence. Here he resided for nearly 10 years, until Francis became emperor of Germany, and called him to preside over the collection of coins and medals at Vienna; this post he held until his death. His complete works, chiefly on numismatics, were published in 1786, at St. Petersburg and Basel, by Koch.

DUVAUCEL, Alfred, a French naturalist, born in Paris in 1792, died in Madras, India, in Aug. 1824. He entered the military service at an early age, and gained some distinction at the siege of Antwerp in 1814. After the restoration of the Bourbons, under the influence of Cuvier, who had married his mother, he turned his attention to the study of natural history. In 1818 he was sent on a scientific expedition to India, where, with his colleague Diard, he formed at Chandernagore a museum of natural history. They prosecuted their researches for several years with success, and at different times sent to Paris 4 large collections of animals.

DUVERGIER DE HAURANNE, Jean, a French theologian, born in Bayonne in 1581, died Oct. 11, 1643. He was educated in theology at Louvain, where Jansenius was at the same time a student, and these two young ecclesiastics formed an intimate friendship. While Jansenius was working upon his *Augustinus*,

Duvergier was appointed to the abbey of St. Cyran. Preserving an ascetic exterior, a regular life, and an inflexible character, he introduced into his monastery the rules of St. Benedict in all their severity. His rigor and zeal becoming known, he was invited to Paris, where he made numerous disciples in all classes of society, and obtained great reputation and influence as the confessor of noble women who were inclined to the severity of asceticism. He refused several bishoprics. His Jansenist principles brought upon him the enmity of the Jesuits, and in 1638, complaints having been borne to Richelieu, he was by order of that minister imprisoned at Vincennes. He lived but a short time after his release upon the death of Richelieu. His most celebrated writings are those which he directed against the Jesuit Garasse. Pascal, Arnauld, and Nicole were his disciples.—Prosper, a French politician and author, born in Rouen, Aug. 3, 1798. In 1831 he was chosen to the chamber of deputies from Sancerre, and at first gave his support to the government of Louis Philippe. Subsequently, however, he became one of the prominent champions of reform. After the revolution of 1848 he represented the department of Cher in the constituent assembly, and in Nov. 1850, became a member of the legislative assembly. After the *coup d'état* of Dec. 2, 1851, he was imprisoned in the fortress of Vincennes, and afterward banished from the country until Aug. 1852, when he received permission to return. Many of his writings, which originally appeared in the *Revue des deux mondes*, have been published; and the 3d volume of his *Histoire du gouvernement parlementaire en France* appeared at Paris in 1859.

DUVERNOY, Georges Louis, a French naturalist, born in Montbéliard, Aug. 6, 1777, died in Paris, March 1, 1855. He pursued his studies at Stuttgart, Strasbourg, and Paris, and in 1802 was invited by Cuvier, to whom he was related, to assist in editing his treatise on comparative anatomy. With the aid of the notes and counsels of his master, he prepared the last 3 volumes of this work, embracing the organs of digestion, respiration, circulation, generation, and the secretions. He returned to Montbéliard, where for 20 years he practised medicine, publishing only a few writings on fossils. In 1827 he was elected professor of the faculty of sciences at Strasbourg, where, during 10 years, he published a variety of papers on anatomical subjects; and after the death of Cuvier he was engaged in arranging his papers for publication. In 1837 he was elected professor of natural history in the college of France. He has published numerous works, which have furnished important materials to anatomists and zoologists.

DUYCKINCK, Evert Augustus, an American author, a son of Evert Duyckinck, for many years a leading bookseller and publisher of New York, born in that city in 1816. He was graduated at Columbia College in 1835. In Dec. 1840, he commenced with Mr. Cornelius Mathews a monthly periodical entitled "Arcturus: a Magazine of Books and Opinion," which was continued until May, 1842. He was also a contributor to the early numbers of the "New York Review." In 1847 he commenced the "Literary World," a weekly critical journal; he withdrew from the editorship with the publication of the 12th number, but resumed the post on the appearance of the 88th, in connection with his brother George L. Duyckinck. The periodical remained under their joint management until its discontinuance at the close of the year 1853. In 1856 the two brothers completed the "Cyclopædia of American Literature" (2 large vols. 8vo.), a work of great research and value. In the same year Mr. Duyckinck published the "Wit and Wisdom of Sydney Smith," a selection from the works of that author, with an original memoir. He has also contributed largely to several periodicals.—George Long, brother of the preceding, born in New York in 1823, was graduated at the university of that city in 1843. In addition to his share in the "Literary World" and "Cyclopædia of American Literature," he is the author of "George Herbert of Bemerton," published in 1858, and a life of Bishop Thomas Ken (1859).

DWARACA, or Jigat, a town of Guzerat, Hindostan, at the western extremity of the peninsula of Cattywar. It is fabled to have been the residence of Krishna, and is the seat of a celebrated temple of that divinity, with a spire 140 feet in height, consisting of a series of pyramids. It is annually resorted to by 15,000 pilgrims. It contains about 2,500 houses, and has an important trade in chalk.

DWARF (Sax. *dwerg*, *dweorg*), an animal or a plant that does not attain the ordinary size of its species. A degree of dwarfishness may be the general result of natural causes, as of excessive cold, since both plants and animals diminish in stature toward the poles; or may be produced by artificial means, as lack of nourishment, compression, or mutilation. The growth of young animals may be arrested by exciting aliments and alcoholic drinks and lotions. Plants may be forced by heat to a precocious inflorescence and fructification, which prevents them from ever attaining their perfect stature. The Chinese have the art of dwarfing trees by diverting the growth from the foliage to the flowers and fruit. The ancients are said even to have produced artificial dwarfs of the human race, who were highly esteemed by the Roman matrons for servants. A race of dwarfs, perhaps the pigmies of the ancients, has been said to exist in the interior of Africa. (See Dokos.) Dwarfs are the exceptions and freaks of nature, and when symmetrical are rare and remarkable phenomena. One of the most noted of those whose history is certain was the Polish gentleman, Count Borowlaski or Boruslawski (1739–1837), whose reputation was European. At 1 year of age, he was 14 inches in height; at 6, 17 in.; at 10, 21 in.; at 15, 25 in.; at 20, 28 in.; at 25, 35 in., which was nearly his greatest height. He early displayed wit and

grace, and was taken into the family of the countess Humiecka, with whom he frequented the Prussian court. He excelled in dancing and in playing on the guitar, and so delighted the Parisian ladies during the year of his residence in that capital that he was once invited to an entertainment in his honor, at which the plate, knives, forks, and spoons were all of dimensions proportioned to his size. At the age of 40 he married, became a father, and, after giving concerts in the principal cities of Germany, visited England, where he was introduced to the royal family, and paid a visit to a giant 8 feet 4 inches high. In London he wrote his memoirs (8vo., 1788), the undertaking being patronized by the prince of Wales and many of the nobility, and he afterward lived in elegant retirement in Durham. He possessed superior intelligence, and was said to exhibit most painful emotions when he perceived himself regarded only as a puppet and a toy. In contrast with him was the favorite dwarf of the ex-king Stanislas of Poland, commonly called Bébé (1741–'64). He was a native of Lorraine, and at 5 years of age was 22 inches high; at 15, 29 inches; and at his death, 33 inches. His diminutive figure was well formed and justly proportioned, till after the age of puberty his spine curved, and he became decrepit. He was never either mentally or physically active. He was once visited by the count Borowlaski, and having noticed the superiority of the latter in manners and intelligence, watched for an opportunity and attempted to throw his visitor into the fire. There was a struggle between the rivals, which was terminated by the interference of the household. The Dutch dwarf, Wybrand Lolkes, born in 1730, possessed mechanical tastes and skill, had success as a watchmaker, and when 60 years of age was 27 inches high, and weighed 56 lbs. Mme. Teresia, called the Corsican fairy, from the place of her birth (1743), was remarkable for physical symmetry and beauty, and mental vivacity. She spoke several languages, was charming in conversation, and when exhibited in London in 1773 was 34 inches high, and weighed 26 lbs. Jeffery Hudson (1619–'82) was the favorite dwarf of Charles I. of England. He was a native of Oakham, and about the age of 7 years, when 18 inches high, was taken into the service of the duke of Buckingham. From the age of 7 to 30 he grew no taller, but afterward shot up to 3 feet 9 inches. He was served up in a pie at a royal entertainment, from which he suddenly sprang forth in full armor. Sir William Davenant wrote a poem called "Jeffreidos" on a battle between him and a turkey cock, when a woman rescued him from his furious antagonist. The courtiers teased him about the story till he challenged a young gentleman, Mr. Crofts, who had affronted him. That gentleman appeared at the rendezvous armed only with a squirt, which so enraged the dwarf that a real duel ensued. The weapons were pistols, and both parties were on horseback to put them more on a level. At the first fire Jeffery shot his antagonist dead. He was afterward taken prisoner by a Turkish rover, and was for a time a slave in Barbary. At the beginning of the civil war he was made captain in the royal army, but he closed his life in prison, into which he had been cast shortly before his death on suspicion of being privy to the popish plot. Charles I. of England honored with his presence the marriage of two dwarfs, Richard Gibson and Anne Shepherd, each of whom measured 3 feet 10 inches. Waller wrote a poem on the occasion, and Sir Peter Lely painted the couple at full length. Gibson rose to celebrity as a painter. In 1710 Peter, czar of Russia, celebrated a marriage of dwarfs with great parade. All the dwarf men and women within 200 miles were ordered to repair to the capital. He supplied carriages for them, and so managed that one horse should be seen galloping into the city with 12 or more of them. The whole company of dwarfs amounted to 70, and all the furniture and other preparations for them were on a miniature scale. Gen. Tom Thumb (Charles S. Stratton), the celebrated American dwarf, was born in Bridgeport, Conn., in 1837, and at the age of 5 years was not 2 feet in height and weighed less than 16 pounds; and he had grown but very little for 3 or 4 years. He had fine talents, and was remarkable for agility and symmetry, while his lively sense of the ludicrous gave him excellent success in performances suited to his character. In 1842 he was exhibited in New York by P. T. Barnum, his age being announced as 11 years. He visited England in 1844, was several times exhibited to the queen and court at Buckingham palace, gave levees, and was invited to parties of the nobility. In Paris he gained applause as an actor. He returned to the United States in 1847, and was publicly exhibited in the principal cities of the United States and in Havana. During the middle ages dwarfs shared with fools the favor of courts and of the nobility, and a salary for the king's dwarf was not abolished in France till the reign of Louis XIV. In character they have usually manifested the faults of spoiled children, being petulant, choleric, envious, jealous, and inconstant. It was asserted by Lavater that no person above or below the ordinary standard of mankind had ever attained eminence for extraordinary talent.—In Scandinavian mythology dwarfs (*Dvergar*) are inhabitants of the interior of the earth, and especially of large isolated rocks. They were imagined to be dark in aspect like the caverns in which they dwelt, and were often styled "dark elves." A dwarf was set by the gods at the corner of each of the 4 quarters of the earth to bear up the sky; and they were named East, West, North, and South. All the dwarfs were esteemed great artists in working metals, and weapons of marvellous properties were said to be produced from their subterranean workshops. Like the Jotuns, they could not endure the sunlight, and if its rays touched them they were turned into stone. If a man met a dwarf away from his rock, and

could throw steel between him and it, it was believed that thereby his habitation was closed up, and that any thing in his power could be extorted from him. In the old Norse, echo is called the "dwarf language," probably because it was thought to be produced by the dwarfs within mountains imitating the sounds which they heard without.

DWIGHT, Edmund, an American merchant, born in Springfield, Mass., Nov. 28, 1780, died in Boston, April 1, 1849. He was the 3d son of Jonathan Dwight (born in Halifax, N. S., June, 1743), who removed to Springfield in his early youth, and from humble beginnings became one of the most successful merchants in New England. He was graduated at Yale college in 1799, and entered the office of Fisher Ames at Dedham, as a student of law. After completing his studies, he made the tour of Europe, and returned to Massachusetts in 1804, and opened a law office in Boston. But in 1807 he accepted an offer from his elder brother, James Scutt Dwight, to become a partner in an extensive mercantile business in Springfield, and for many years he continued that connection. In April, 1809, he married a daughter of Samuel Eliot of Boston, and in 1815 removed with his family to that city, where he established the mercantile house of William H. and J. W. Dwight. Mr. William H. Dwight was lost by shipwreck on the coast of Ireland, in 1822, and when Mr. J. W. Dwight retired from business the house was continued until 1853, under the name of James K. Mills and co. It may be said that, with perhaps one or two exceptions, this house has laid the foundation of more successful manufacturing enterprises than any other in New England. In 1822 the manufacturing village of Chicopee Falls was commenced by it, and in the course of 7 years 4 large cotton mills were put in motion, beside manufactories of other fabrics. In 1831 measures were taken to develop the water power at Cabotville (since Chicopee), and in a few years 7 large cotton mills were erected and set in successful operation there, beside manufactories of machinery, tools, hardware, brass cannons, bells, &c. In 1847 measures were taken to form an immense water power on the Connecticut river in the northerly part of West Springfield, opposite South Hadley, and a village was laid out called Holyoke. Notwithstanding many discouraging circumstances, this has acquired a very respectable standing among the manufacturing towns in New England. Another enterprise of a more public character, in which Mr. Dwight took an early and active part, was the construction of the Western railroad from Worcester to Albany, of which he was a director for many years, and one year president. But the great feature of his life was his eminent services to the cause of popular education. Mr. Dwight was the first to propose the establishment of normal schools in Massachusetts, but the extent of his liberality in the contributions of pecuniary means for that object was not allowed to be publicly known until his decease. In 1838 he pledged $10,000 for the purpose of establishing a system of normal schools, provided the state would appropriate a like sum for the purpose. The proposition was promptly accepted by the legislature. It appeared after his death that Mr. Dwight had relieved several deserving young men who were struggling to meet the expenses of an education, without allowing the receivers of his bounty to know the hand that had helped them. During most of his business life he represented the towns in which he resided in the legislature. He was a member from Boston for several years.

DWIGHT, Theodore, an American author and journalist, born in Northampton, Mass., in 1765, died in New York, June 11, 1846. He was a brother of Timothy Dwight, and a grandson, on the mother's side, of Jonathan Edwards, and studied law with his uncle, Judge Pierpont Edwards, of Hartford, Conn. He became an eminent member of his profession, and a leading speaker and writer of the federal party. As a senator in the Connecticut legislature, and subsequently a representative in congress from that state in 1806–'7, he showed an aptitude for the discussion of public affairs which induced the prominent federalists of Connecticut to secure his services as editor of the "Hartford Mirror," the leading organ of the party in the state. During the session of the Hartford convention in 1814 he acted as its secretary, and in 1833 published a "History of the Hartford Convention," written from a strong federal point of view. Between 1815 and 1817 he edited the "Albany Daily Advertiser," and in the latter year removed to New York, where he established the "New York Daily Advertiser," of which he remained the editor until 1836, when he retired from professional life to reside in Hartford. Three years before his death he returned to New York. Mr. Dwight was the author of some occasional orations and of several educational works.

DWIGHT, Timothy, an American divine, president of Yale college, born in Northampton, Mass., May 14, 1752, died in New Haven, Conn., Jan. 11, 1817. From his earliest years, under the training of his mother, he gave indications of a thirst for knowledge, and great facility of learning. He is said to have been able at the age of 4 to read the Bible correctly and fluently. When 6 years old he was sent to the grammar school, and in 1765 he entered Yale college, where, for the first 2 years, he scarcely fulfilled the promise of his earlier days; but from that time to the end of his college course, he made rapid progress in his regular studies and in other branches, especially in poetry and music. He was graduated in 1769, and soon took charge of a grammar school in New Haven, where he remained for 2 years. In 1771 he was chosen tutor in Yale college, and continued in that office for 6 years. So intense and unintermitted were his studies at this time that his health was for a season seriously impaired, and his eyes so weakened that they never regained their strength. For a

time he seems to have contemplated the study of law, in which he afterward temporarily engaged, though his ultimate determination was for theology. When, on account of the revolutionary troubles, the students of the college were dispersed, in 1777, he went with his class to Wethersfield, where he remained till autumn, and in the mean time was licensed to preach by an association in Hampshire co., Mass. Soon after this he was appointed chaplain to a brigade of the division under Gen. Putnam, and joined the army at West Point, remaining with them over a year, and discharging the duties of his office with scrupulous fidelity. Not only did he labor for the spiritual interests of the soldiery, but, by delivering patriotic discourses and composing patriotic songs, gave new vigor to the spirit of liberty. By the death of his father in 1778 the support of his mother with her 12 children devolved on him, the oldest of her sons; and resigning his chaplaincy, he removed with his own family to Northampton. Here his labors for a series of years would seem almost incredible. He worked with his own hands upon the farm during the week, supplied some neighboring church on the Sabbath, established and sustained a school for both sexes, which acquired high celebrity, represented the town in county conventions, and for 2 years in the state legislature, and would have been chosen to the continental congress, but that he declined the intended honor, in order to devote himself to the work of the ministry. In 1783 he was ordained as pastor of the Congregational church in Greenfield, Conn.; but as his salary was entirely insufficient for his support, he established an academy, which soon became extensively known, and to which he devoted 6 hours of each day. In 1787 he received the degree of D.D. from the college of New Jersey, and in 1810 that of LL.D. from Harvard college. On the death of Dr. Stiles he was chosen his successor in the presidency of Yale college, was inaugurated to that office in Sept. 1795, and continued in it to the end of his life, not merely, however, discharging its appropriate duties, but connecting with it a vast amount of labor that belonged to other departments. He was, in reality, professor of belles-lettres, oratory, and theology, teaching a class preparing for the ministry, and preaching in the college chapel twice every Sunday; in the discharge of which latter duty he prepared and delivered his well-known "System of Theology," with which his reputation as a writer and preacher is chiefly identified. In 1816 his health began to give way under his labors, and though he attended to his classes and heard recitations almost to the last, he gradually declined till the hour of his death. Dr. Dwight was a man of commanding presence, of dignified but affable manners, of striking conversational powers, of superior intellectual faculties, untiring in his industry and research, of great system and wonderful memory; as a teacher, remarkable for his skill and success; as a writer always interesting and sensible; and as a preacher, sound, strong, impressive, and at times highly eloquent. So entirely were his mental resources under his command, that he often dictated to 2 or even 3 amanuenses at the same time, on as many distinct subjects; and so great was his influence over young men, and his success in training large numbers of them for eminence and usefulness, that a distinguished civilian has said of him: "I have often expressed the opinion, which length of time has continually strengthened, that no man except the 'father of his country' has conferred greater benefits on our nation than President Dwight." The literary labors of Dr. Dwight were very great, and his publications numerous, consisting of dissertations, poems, and occasional sermons, issued during his life, and since his death; his "Theology Explained and Defended," with a memoir (5 vols., 1818); "Travels in New England and New York" (4 vols., 1822); "Sermons on Miscellaneous Subjects" (2 vols., 1828).—Sereno Edwards, an American clergyman, son of the preceding, born in Greenfield, Conn., May 18, 1786, died in Philadelphia, Nov. 30, 1850. When between 9 and 10 years of age, he was removed to New Haven, his father having then become president of Yale college. Entering that institution in 1799, he was graduated in 1803; was tutor in Yale college from 1806 to 1810, during which time he studied law in New Haven, and was admitted to the bar in the latter year. In 1815, however, he experienced, as he believed, a radical change of character, and in October of the year following was licensed as a preacher of the gospel by the west association of New Haven co. Soon afterward he was chosen chaplain of the U. S. senate for the session of 1816–'17, and in September of the latter year was ordained pastor of the Park street church, Boston. Here he labored with great zeal and success for about 10 years, visiting Europe, in 1824–'25, to recruit his prostrated health; but not fully gaining this end, he resigned his charge in 1826. Returning to New Haven, he now occupied himself in writing the life and editing the works of the elder President Edwards, which were published in 1829. In 1828, in connection with his brother Henry, he commenced in New Haven a large school for boys, on the plan of the German gymnasiums, which was continued for 3 years. In March, 1833, he was chosen president of Hamilton college, N. Y., in September of the same year received the degree of D.D. from Yale college, and in Sept. 1835, on account of pecuniary and other discouragements, resigned his presidency. In 1838 he was occupied for some months in an agency for the Pennsylvania colonization society, and in the same year removed to New York, where he lived for the remainder of his days. Here a distressing malady, from which he had long suffered, gained complete mastery over him, disabling him for active service, and leading him to court retirement, so that little was known of him by the public, till, visiting Philadelphia in

1850, for medical aid, he was seized with the illness that terminated his life. He published at various times several sermons and addresses, the "Life of Brainerd" (1822), a volume on the "Atonement" (1826), the "Life of Edwards" (1830), and the "Hebrew Wife" (1836). A volume of his "Select Discourses" was published in 1851, together with an interesting memoir by his brother, the Rev. Dr. W. T. Dwight.

DWINA, or DVINA, NORTHERN, a river of Russia in Europe, formed in the government of Vologda by the junction of the Sookhona and Vitchegda, flows N. N. W. into the government of Archangel, where it receives several tributaries, and after a course of more than 400 miles falls through several mouths, forming a number of islands, into the White sea, about 40 miles below the city of Archangel. It is navigable for its whole length, and is the largest stream in northern Europe, traversing as it does a marshy country, and increased by numerous affluents. It forms a part of a system of canals completed in 1807, by which a water communication is established between the White, Baltic, Black, and Caspian seas. (For SOUTHERN DWINA, see DÜNA.)

DYAKS. See BORNEO.

DYCE, ALEXANDER, a Scottish author, born in Edinburgh, June 30, 1797. He completed his education at Exeter college, Oxford, subsequently took orders, and in 1827 settled in London, where he has since lived. He has edited, with notes and biographies, editions of the works of Peele, Greene, Webster, Middleton, Beaumont and Fletcher, Marlow, and Shirley. In 1856 he edited "Recollections of the Table Talk of Samuel Rogers;" and in 1858 he completed an edition of Shakespeare in 6 vols., the text of which has been highly commended. He has also contributed biographies for Pickering's "Aldine Poets." Among his miscellaneous publications are: "Select Translations from Quintus Smyrnæus;" editions of Collins's and Skelton's poems; "Specimens of British Poetesses;" Kemp's "Nine Days' Wonder," and some old plays. To Shakespearean literature he has contributed "Remarks on Collier's and Knight's Editions of Shakespeare," and "A few Notes on Shakespeare"—a review of the recent emendations proposed by Mr. Collier.—WILLIAM, a British artist, born in Scotland at the beginning of this century. He studied painting at the academy of Edinburgh, but attracted little notice until the production of his fresco studies in the exhibition at Westminster hall in 1844. The admirable manner in which these were executed procured him commissions to make designs for the new houses of parliament. His "Baptism of Ethelbert," on one of the mural compartments of the new house of lords, is regarded as one of his best works. He was made a royal academician in 1848. Among his pictures exhibited in London in 1851 was "Lear in the Storm," and in Paris in 1855, "Meeting of Jacob and Rachel," and "King Joash shooting the Arrow of Deliverance."

DYEING. Among the earliest records of the human race we find frequent intimations of an appreciation of the brilliant hues such as are displayed by nature in the plumage of birds, in flowers, crystals, and shells, and in the morning and evening sky; and the instinct implanted in man of imitating the works of his Creator is seen in the desire to appropriate these rich colors to the adornment of his own apparel. The gift of the coat of many colors was early regarded as the highest mark of affection. To the fine linen (which was probably the same as our cotton) were transferred the brilliant blue, scarlet, and purple hues extracted from vegetable or animal substances, the last named color reserved exclusively for the vestments of kings and high priests. The skins of the ram and the badger made use of for the tabernacle were dyed red, and in the time of Moses the art of coloring woollen purple was already known. The Tyrians early attained a high perfection in the art, and their king sent to Solomon a man skilful to work "in purple and blue, and in fine linen and in crimson." Along the coast of Phœnicia they found the two kinds of shellfish called by Pliny the *buccinum* and *purpura*, and from each animal they extracted a single drop of the precious juice which caused their name to be ever associated with the rich purple dye. In such estimation was this held in the time of the Roman emperors, that a pound weight of the cloth which had been twice dipped in it was sold, as Pliny states, for a sum worth about $150. But its use being restricted to the emperors, the art of preparing it was at last lost. It was revived in the 17th and 18th centuries in England and France, but better colors and cheaper processes were then in use. The discoverers and early conquerors of the countries of North and South America were astonished by the skill exhibited by the ancient Peruvians and Mexicans in the application of the numerous beautiful dyes they extracted from the woods of their forests. According to Pliny, the methods of dyeing black, blue, yellow, and green were brought into Greece on the return of the expedition of Alexander the Great from India, where it appears that the art of coloring cotton cloths with rich and permanent dyes had long been known and practised. The Venetians and Genoese in the height of their prosperity, in the time of the crusades, transferred the art to Italy; and Florence in the early part of the 14th century, it is said, contained not less than 200 dyeing establishments. The important dye stuff archil was discovered about the year 1300 by a merchant of Florence. In 1429 a work upon dyeing was published in Venice, of which subsequent editions were issued as late as the year 1548, containing full details of the processes employed. From this work it would appear that the use of indigo was unknown in Europe up to 1548, though in India it was probably an important article in dyeing at the remotest periods. It was afterward introduced from America together with cochineal,

logwood, annotto, quercitron, Brazil wood, &c. But its use in England and Saxony, as of logwood also, met with the most determined opposition. The cultivators of the woad then in use for dyeing blue caused decrees to be issued against indigo as a most dangerous product. By the German diet in 1577 it was declared to be "a pernicious, deceitful, eating, and corrosive dye;" and the name was given it of food for the devil. An act of parliament in the reign of Elizabeth forbade its use, and authorized the destruction of it and of logwood wherever found, and this continued in force for nearly a century. About the year 1630 it was discovered that the crimson color obtained from cochineal might be converted into a brilliant scarlet by the application of a salt of tin. The introduction of this metal as an occasional substitute for alum as a mordant is attributed to a dyer named Cornelius Drebbel. The use of pure mordants marks the great improvement of the art in modern times, as also the introduction of a great variety of new dyes obtained from mineral substances. The Flemings during the 17th century carried the skill to which they had attained in this art into Germany, France, and England. The French about the same time directed particular attention to it, and men of eminence in chemical science, as Du Fay, Hellot, Macquer, and Berthollet, were appointed by the government to investigate and perfect the processes. The method practised in the East of giving to cotton the beautiful and permanent Turkey red dye was made known in their publications, and the art was about the same time introduced into France by some Greek dyers. The business was afterward permanently established at Glasgow by a Frenchman named Papillon. The branch of dyeing called calico printing, by which different colors are produced on the same piece of cloth by dipping it into a dye of one color, was known at a very early period, and the process is lucidly described in a few words by Pliny, as it was practised in Egypt in the first century. (See Calico.)—The object to be attained by dyeing is the fixing of certain colors permanently and so as to present a uniform shade in the fibres of textile materials and other substances. The subjects operated upon are various in their characters, some being of animal origin, as silks and woollens, and others being composed of vegetable matters alone, as cottons, linens, &c. These two classes differ in the facility with which they imbibe the coloring matters, the animal tissue taking much more brilliant shades than the vegetable. The colors may be applied to each of these in the raw fibre, in the spun yarn, or in the woven fabric. Hence it is apparent that there must be much diversity in the processes. But when it is further considered that the coloring matters are themselves of the most diverse composition, drawn from the vegetable, animal, and mineral kingdoms, and that different substances are brought together to produce by their reactions effects dependent on the intricate changes which take place among the elements of organic bodies, the art is readily understood to be exceedingly complicated in its nature, and to some extent so empirical in its processes, that its exposition must involve a vast amount of details. In an article like the present only a general idea of the principles of the art and of the materials employed can be given.—The colors obtained from vegetable matters are most numerous; they are extracted generally by watery infusion, though some require for their solution ether, alcohol, or the fixed oils. The most common colors are yellow, brown, and red; the only blue vegetable dyes are litmus and indigo; nut galls, sumach, and the cashew nut afford a black dye; and by the mixing of these, or their treatment with other substances, numerous shades or even different colors are obtained. The animal kingdom affords the beautiful scarlet and crimson dyes, which are extracted from the bodies of the cochineal and kermes insects. Hoofs and horns and other refuse animal matters yield the cyanogen which enters into the composition of Prussian blue. From the mineral kingdom is derived a great variety of brilliant colors, produced from the salts of the different metals. The same metal in its various combinations gives many colors, as is seen in the crystals of its natural salts. Thus iron in the form of a sulphate furnishes the ancient nankeen or iron buff, as a nitrate it affords various shades of blue, and in other combinations it is made to yield a black, slate color, &c. The chrome and lead salts are particularly interesting for the variety and brilliancy of their colors. The former are remarkable for their permanency also, and the extent of their possible applications is by no means yet fully appreciated. The mordants also, which are used to prepare the fibre for the reception and fixing of the dye, come almost wholly from the mineral kingdom. They are soluble combinations of alumina, of protoxide of lead, of oxide of iron, or of oxide of tin or of copper, with some acid, commonly acetic acid. Materials to be dyed seldom have such an affinity for the coloring matters that they will receive these without previous preparation. Some few colors, however, which are technically called substantive, are applied directly to the stuffs, and become fixed without the intervention of any other matter. But mordants are commonly required. They have the property of fixing themselves to the fibre, and of uniting chemically with the dye afterward applied, thus binding them fast together. The name is given them from the old opinion that their action was mechanical, and that they bit into (Lat. *mordeo*) and opened the pores of the fibre for the reception of the coloring matters. Some of them serve, at the same time that they fix the color, to modify its shade, and give to it its highest tone. For these the name alterants has been proposed by Berthollet, to distinguish them from the simple mordants. Oxide of iron often has this effect of changing the ordinary colors of a dye. Thus a

decoction of madder applied to unmordanted cotton gives a fugitive and dirty red color. If the cotton be first passed through a weak solution of acetate of alumina, and then dried at a high temperature, afterward washed, next treated with a hot decoction of madder, and again washed, it will be found to have received a fine red, which is fixed, so as to resist the action of air, light, and water. But if, instead of alumina, oxide of iron is employed as the mordant, a purple color will be obtained. So in dyeing with cochineal, the aluminous mordant produces a crimson color; but if oxide of iron is used instead, the result is black. By mixing mordants different shades and colors are produced, and varying the strength of the solutions, and other similar expedients, afford opportunities for the exercise of much ingenuity in obtaining a variety of effects. A thorough familiarity with the chemical action of the salts employed upon each other is essential to skilfully conduct these complicated processes, and obtain most directly and with the greatest economy the effects desired. It is often the case that the color is produced in the cloth in the form of a precipitate by the interchange of the elements of 2 different chemical compounds taking place in the fibre of the stuff, on this being dipped first into the solution of one, and then into that of the other. The new color obtained by this chemical reaction is at the same time fixed in the fibre, as though one of the substances acted as a mordant; this may be the case when neither solution would afford any color whatever to the material to be dyed. Thus an aqueous solution of nitrate or acetate of lead or of bichromate of potash imparts no color to cloth; if applied to it, either may be washed out; but one being applied to the same stuff after it has received the other, an insoluble precipitate of chrome yellow (chromate of lead) is obtained, which attaches itself to the stuff as a fast dye. The oxygen of the air is also made to act upon colors subject to its influence, bringing them out as the material exposed to it is converted into an oxide. Solutions of salts which evolve oxygen are used to produce the same effect. Acids, too, are added to alkaline solutions to neutralize them and cause the dye they hold in solution to be liberated as they precipitate among the fibres of the cloth. In the process called mandarining an acid is made to act directly upon the fibre of the cloth, which in this case must be of animal substance, as silk or woollen. An orange dye is thus produced by the action of dilute nitric acid.—An interesting account is given by Tomlinson, in the "Useful Arts and Manufactures of Great Britain," of the operations conducted in one of the great English cotton dye houses, near Bolton. In an immense apartment, the basement story of a large cotton mill, is collected the great variety of apparatus employed: cisterns of stone for bleaching and washing; dash-wheels, &c., also for washing; "dye becks" and "soap becks," or vessels containing the dye-stuffs and the soap and water; mangles for rolling cloth, others with brushes for laying the fibre, squeezing rollers, and drying machines. Boilers are seen in operation heated by steam conveyed through them in pipes; water flows in every direction, the waste running out in streams of all colors, and the fresh conveyed about by numerous pipes. The water must be of the purest quality, uncontaminated by any foreign substances, whose presence would injuriously affect the delicate chemical processes. The dyestuffs are ground and mixed in another room, where they are also stored. The infusions are made in tubs or vats, some in cold water, and some by boiling. The dyestuffs are introduced in the form of a coarse powder, or they may be enclosed in bags through which the color is imparted to the liquid. The cotton cloth is first prepared by thorough cleansing in order to remove all extraneous matters that may be attached to the fibre; acid waters are sometimes used for this purpose, dissolving out the calcareous earth and oxide of iron which are frequently present. The mordant is then applied by soaking the cloth in solutions of alum, each pound of cotton requiring 4 oz. of alum; or if a black color is to be produced, the mordant is a preparation of nut galls boiled for 2 hours in water. The preparatory operations are expedited by passing the cloth in lengths of 100 yards or more over and under different rollers, one of which is set under the liquid in the vat. The fluid is thus kept uniformly mixed, and the cloth is equally saturated with it. As it comes out of the vat it is made to pass between 2 rollers, which press out the superfluous moisture, and it is then ready for another dipping. After the dyeing has been completed, the cloth must be submitted to the finishing processes. The loose portions of the coloring matters are removed by washing, and the colors are brightened and rendered more permanent by passing the cloth through solutions of cow dung in water, or of the artificial preparations of phosphates used as a substitute and called by this name, or a solution of bran is used to effect a similar purpose. These are processes adopted in calico printing particularly, as is that of fixing the colors by steaming the cloth. Chloride of lime in solution is also employed to remove the excess of coloring matters. By next passing the cloth through squeezing rollers the water is pressed out, and in the drying machine it is in a few minutes rendered nearly dry, the centrifugal force produced by the rapid revolution of a cylinder expelling the moisture, which escapes through apertures made for the purpose. The starching and subsequent drying by steam follow, and the cloth is ready for the final process of calendering.—In 1850 a patent was granted in England to Mr. Jean Adolphe Carton for improvements in dyeing, which consist in the preparation of 4 mordants to be used instead of the cream of tartar, and cream of tartar and alum, now commonly employed, whereby colors will be produced at a cheaper rate and of superior brilliancy and variety. The first mordant is prepared by

dissolving 18 parts by weight of common salt and 9 parts of tartaric acid in 67 parts of boiling water, and then adding 18 parts of the acetic acid of commerce. One pound of this mordant is equivalent for dyeing purposes to about one pound of cream of tartar, and it is used in the same manner. It is suitable for crimson and all reddish dyes. The second mordant is produced by triturating and mixing one part of alum with 2 parts of the residuum (sulphate of soda) of that mode of manufacturing nitric acid in which nitrate of soda is employed. Two and a quarter pounds of this mordant are equivalent to half that quantity of cream of tartar, and it is to be used in the same way. It is suitable for all olive and brown dyes. The 3d mordant is prepared by triturating and mixing together 5 parts of common salt and one part of the residuum of the manufacture of sulphuric acid where nitrate of potash is employed. This mordant is to be used in the same proportion to cream of tartar as the 2d, and it is applicable to black and dark colors only. The 4th mordant is formed by dissolving 6 parts of alumina, 3 parts of nitric acid, and 1 part of caustic ley of 24° Beaumé in 20 quarts of boiling water. It may be used in dyers' baths for green dyes of all shades and fancy dyes, in the proportion of one pint for every 20 lbs. weight of the fabrics to be dyed.—Many experiments in dyeing made by M. Kuhlmann were published in France at the beginning of 1859. This gentleman having remarked that when eggs were dyed some of them took colors better than others, and that this fixation of the color took place without any mordant, was led to suppose that, in these cases, the fixation was not due to the calcareous salt of which the egg shell is formed, but to the azotized coating upon its surface. This supposition was subsequently verified by experiment. As the coating of the egg shell is analogous to albumen, this latter substance, coagulated by heat, was tried separately in baths of Brazil wood, &c., and its absorbing power thus shown. M. Kuhlmann then tried the use of this substance for the purpose of increasing the absorbing power of different tissues, and obtained very favorable results with cotton, less distinct with silk, scarcely perceptible with wool; these trials were made with Brazil wood, madder, and Campeachy wood. After albumen he tried with the same success milk and caseum, which may be coagulated on the surface of the tissues by means of an acid. Milk especially, alone or in connection with mordants, gave the cotton very full colors. He experimented also upon gelatine coagulated by tannin, and obtained results, although feeble, without mordants. He also found that albumen may serve as a medium for precipitating upon stuffs metallic oxides, with which it forms insoluble compounds; in dyeing, stuffs impregnated with these compounds absorb colors with more ease than if they had been prepared with albumen, or with the same metallic salts alone. Analogous results were obtained with tannin-gelatine.

—See Bancroft's "Experimental Researches concerning the Philosophy of Permanent Colors" (1796). A very complete treatise upon dyeing is contained in the new work of "Chemistry applied to the Arts and Manufactures," by Dr. Muspratt. The principal French works on dyeing are: A. Vinçard, *L'art du teinturier* (1820); J. B. Vitalis, *Cours élémentaire de teinture* (1823); M. Chevreuil, *Cours de chimie appliquée à la teinture* (1831); Berthollet, *Les éléments de l'art de la teinture* (1840); and still more recently, *Manuel du teinturier*, by M. Verguiaud (in the handbooks on industry published by Rozet). Among the German works lately published on the subject are: Schrader, *Die Färberei im Kleinen* (2d edit. Leipsic, 1857); Leuchs, *Verbesserungen in der Farbenfabrikation* (Nuremberg, 1857); and Kurrer, *Das Neueste der Druck- und Färbekunst* (Berlin, 1858).

DYER, a W. co. of Tenn., separated from Mo. by the Mississippi river, and drained by Obion and Forked Deer rivers; area estimated at 400 sq. m.; pop. in 1850, 6,361, of whom 1,468 were slaves. The soil is rich, and the surface level and partly occupied by excellent timber tracts. Yellow poplar timber forms one of the principal articles of export. The other staples are Indian corn and tobacco. In 1850 the county produced 413,020 bushels of Indian corn, 22,832 of oats, 548,815 lbs. of tobacco, and 59,660 of butter. There were 12 churches and 700 pupils attending public schools. Capital, Dyersburg.

DYER, George, an English author, born in a suburb of London, March 15, 1755, died in London, March 2, 1841. He was educated at Christ's hospital, where he was an associate of Charles Lamb, and at Emmanuel college, Cambridge, where he received the degree of bachelor in 1778. He was successively a teacher, tutor, and Baptist minister, residing most of the time either at Cambridge or Oxford, till in 1792 he removed to London, where he was engaged as parliamentary reporter, teacher, and writer. In 1830 his eyesight failed, and he at length became totally blind. He was a poet and frequent contributor to reviews, but is better known as a scholar and antiquary. He was joint editor of Valpy's combination of the Delphin, Bipont, and Variorum editions of the Latin classics, in 141 volumes, for which he furnished all the original matter except the preface. He published a "History of the University and Colleges of Cambridge" (London, 1814), which is an excellent sketch rather than a complete history. He also published a volume of poems (1812), a life of the Rev. Robert Robinson, a work on the "Privileges of the University of Cambridge" (1824), and another entitled "Academic Unity" (1827). Talfourd refers to his "simplicity of nature, not only unspotted by the world, but almost abstracted from it," and speaks of him as "breathing out at the age of 85 the most blameless of lives, which began in a struggle to end in a learned dream."

DYER, John, an English poet, born at Aberglasney, Caermarthenshire, in 1700, died July 24, 1758. He was educated at Westminster,

and recalled to his native place to follow the profession of his father as solicitor. His taste, however, led him to poetry and the fine arts, and after a short study of painting he rambled over England as an itinerant artist. In 1727 he published his "Grongar Hill," which he had written during his excursions—a poem marked by warmth of sentiment and an elegant simplicity of description. He travelled in Italy to pursue his studies as a painter, but the best result of his observations was his poem entitled the "Ruins of Rome," which was published in 1740. On his return from Italy, having little prospect of success as an artist, he entered holy orders, and married a lady named Ensor, who, he says, was a descendant from Shakespeare. In 1758 appeared his longer poem of "The Fleece," in which he attempted to treat the subject of wool in a poetical manner, and which is at least one of the most successful of the many imitations of Virgil's "Georgics." All the poems of Dyer abound in happy and careful pictures of nature, and in appropriate and gentle moral sentiments. His eulogy is pronounced by Johnson when he says that he who has read "Grongar Hill" once will return to read it a second time.

DYER, Mary, a disciple of Anne Hutchinson, and a victim to the persecution which befell the Quakers in the early history of Massachusetts, was hanged on Boston common, June 1, 1660. The government of Massachusetts by a statute excluded Quakers from the bounds of that colony, and sentenced to death any one of that sect who should be guilty of a second visit to the peculiar land of the Puritans. The statute was little regarded, or rather was construed as an invitation instead of a menace, by the enthusiastic and devoted believers against whom it was directed. Mary Dyer had departed from their jurisdiction upon the enactment of the law, but soon after returned on purpose to offer up her life. She was arrested and sent to prison full of joy, wrote from the gaol a remonstrance in which she pronounced her persecutors disobedient and deceived, was reprieved after being led forth to execution and after the rope had been put around her neck, and was against her will conveyed out of the colony. She speedily returned, and suffered as a willing martyr.

DYMOND, Jonathan, an English writer on ethics, born in Exeter in 1796, died May 6, 1828. The son of a linen draper, and himself engaged in the business, he composed his books amid the pressure of other occupations and without the resources of a learned education. He wrote principally in the early hours of morning, and published in 1823 an "Inquiry into the Accordance of War with the Principles of Christianity," a work which attracted much attention. His fame chiefly rests on his "Essays on the Principles of Morality," which proves him to have possessed a discriminating mind, and simple and clear views of Christian ethics.

DYNAMICS (Gr. δυναμις, force), that department of mechanics which treats abstractly of bodies in motion, as distinguished from statics, which considers bodies at rest. (See Mechanics.)

DYNAMOMETER (Gr. δυναμις, force, and μετρον, a measure), an instrument originally designed to ascertain the strength of men and animals, of the limbs of the body, the fingers, &c. Its application was afterward extended to the determination of the power exerted by machines, or of any portions of them, and the instrument has hence come into use as a meter of the power of engines. The principle of the earlier contrivances was to weigh the force exerted by the amount of compression or of deflection produced upon an elliptical steel spring; this in the former case being drawn together by the application of the power and of the resistance at the two opposite ends, and in the latter separated by the force and resistance being applied upon the opposite sides of the spring, on the line of the minor axis of the ellipse; an index upon a graduated arc attached to the spring showed the amount of deflection. Another contrivance was a spiral spring enclosed in a tube, the force being exerted to draw this together, precisely the same thing as the ordinary spring balance. By such means the greatest power exerted by one impulse was indicated; but as in most instances the power is not constant for any determinate time, the index must fluctuate in such a manner that the mean effort it should represent cannot be ascertained. If known, its amount multiplied by the time of continuance of the operation would give as a result the value of the whole power exerted. Instruments have been devised by MM. Poncelet, Morin, and others, which should register upon papers, made to pass by a clock-work movement under the index, curved lines from which the whole power could be directly calculated from the areas enclosed—the ordinates of the curves representing the power exerted, and the abscissas the length of time, or in some instances of the space run over. The apparatus might be fixed to a carriage, the length of the index paper in this instance bearing a certain proportion to the length of the road gone over. A great number of different forms of this instrument have been devised by eminent engineers of France, England, and the United States. One by Watt, improved by Macknaught, gives the force exerted by the piston of a steam engine against a spiral spring, a style attached to the piston inscribing a line representing its position during the unrolling of the paper which moves at an even rate against it. The principle of this is the same as that of anemometers, which are dynamometers limited in their application to measuring the force of the wind. In the *Dictionnaire des arts et manufactures* the subject is fully treated in the article *Dynamomètre*, by M. Laboulaye. The descriptions of the various forms of the apparatus are made intelligible by many illustrations. In Appleton's "Dictionary of Mechanics," also, many forms of the apparatus are figured and described; and the following simple contrivance, applicable in some instances, is proposed. A cylinder of some material hea-

vier than water is suspended in this fluid by a rope passing over a pulley. As power is applied to this rope to draw the cylinder out of the water, the increasing weight of this, as more is raised into the air, will at last cause the resistance to equal the force applied, the cylinder being sufficiently large and long. By means of a scale properly arranged, the amount of the power applied may be accurately measured.

DYSART, or DESART, a parliamentary borough and seaport town of Scotland, in the county of Fife, 12 m. N. N. E. from Edinburgh, on the N. side of the firth of Forth; pop. in 1851, 8,739. The town is very old, and in former times was a place of much importance. Its trade was then considerable, but it now exports little beside coal, and has no manufactures of note except checks and ticks.

DYSENTERY, a disease characterized by frequent straining efforts at stool, attended by small and painful mucous and bloody discharges. Dysentery is more common in hot climates than in temperate ones; in summer and autumn than in winter and spring. It is subject to epidemic influences, being in some seasons frequent and fatal over an extensive region, and then almost disappearing for years. It is more common and severe in malarious districts. It sometimes breaks out and is excessively fatal in public institutions where the inmates have been subject to the combined influence of a vitiated atmosphere and an improper and innutritious diet; and under the influence of fatigue, exposure, and improper diet, it has often proved very destructive to armies. It is commonly attributed to the use of irritating and indigestible food, and to cold, particularly after the body has been debilitated by a prolonged exposure to heat. The milder cases of dysentery are attended by little or no fever; but when the disease is severe fever is always present, and may precede though it more commonly follows the local manifestations. There is often a good deal of pain and soreness in the lower part of the abdomen or extending along the track of the colon, frequent calls to stool, attended with painful and often violent straining; the stools consist chiefly of mucus more or less tinged with blood, and sometimes mixed with membranous shreds, or they may consist of blood almost pure, or they resemble the washings of flesh; their odor is not feculent, but faint and peculiar, and sometimes horribly fetid; occasionally the neck of the bladder sympathizes with the neighboring bowel, and there is difficulty in passing urine. While mild cases of dysentery are attended with no danger, when severe the disease is always serious and often fatal; or it may become chronic, and slowly waste the powers of the constitution. When death occurs, *post mortem* examination reveals the existence of extensive ulceration in the large intestines. The ulcers are often large, irregular in shape, laying bare the muscular and sometimes the peritoneal coat; between them the mucous membrane is thickened, often lined with false membrane, sometimes appearing as if struck with gangrene. When the pain and tenderness are very considerable, the treatment may be commenced by the application of leeches over the track of the inflamed bowel; if any constipation has previously existed, a dose of castor oil, to which a few drops of laudanum have been added, may be given; opiates and astringents may be afterward administered. From the fact that the rectum is the part of the intestinal canal most affected, opiates in the form of suppositories or enemata are found particularly useful. Calomel has been highly recommended in the treatment of the dysentery of tropical climates, but in temperate regions it is rarely necessary to resort to it. During the treatment the patient should be confined to his bed, and the diet should be of the mildest and most unirritating character. When dysentery passes into the chronic state, the tenesmus subsides, the stools become more copious and loose, and are found to contain pus; the complaint is apt to be tedious and intractable, and when recovery does take place the digestive organs remain for a long time feeble and irritable. A strictly regulated diet with the use of opium, combined with a small dose of sulphate of copper or nitrate of silver, are the means commonly had recourse to in its treatment.

DYSPEPSIA, INDIGESTION. Under this head are commonly grouped all those functional disorders of the stomach which are independent of organic disease, and are not symptomatic of disease of other parts of the economy. Its characteristic symptoms, as given by Cullen, "are want of appetite, nausea, vomiting, flatulence, eructations, and pain; more or fewer of these symptoms concurring, together sometimes with constipation." Many circumstances must concur to render digestion easy and perfect. The mind should be free from any harassing care or anxiety; otherwise not only the appetite is impaired, but the food which is taken is digested with difficulty. The food should be thoroughly masticated and insalivated to prepare it for the action of the gastric juice. Those who bolt their food half chewed, who have salivary fistula, or who waste their saliva by constant spitting, finally suffer from dyspepsia. The quantity of food taken must be suited to the wants of the system, and to the capabilities of the stomach. After recovery from wasting diseases, a larger quantity of food is required and will be digested than at ordinary times. It must be suited to the digestive capacity of the stomach; if the quantity be too large or the quality too rich, a sense of fulness and weight in the region of the stomach, nausea, heartburn, and eructation of acid and gaseous matters follow; with these symptoms the tongue becomes furred, there is some feverishness, and there is more or less headache; if vomiting occurs, and the *ejecta* contain bile, the sufferer in ordinary phrase is said to have had a bilious attack. The food must be taken at proper intervals, and these intervals are not always the same for all

persons; before a second meal is taken, the previous meal should be completely digested, and the stomach should have a period of repose. The food must not only be of a character which permits its easy digestion by the stomach and small intestines, but it must afford a residuum bulky and stimulating enough to maintain a regular action of the bowels. When constipation is induced by neglect, indolent habits, or too concentrated a diet, the stomach is apt to suffer, and dyspeptic symptoms follow. To all these causes of dyspepsia must be added the abuse of fermented and distilled liquors. When dyspepsia has been induced by any one of the above-mentioned causes, its cure is to be sought in the removal of the cause by which it was brought on; but this alone will often be found tedious or inefficient. In one class of cases a certain degree of inflammation of the gastric mucous membrane seems to be produced. The presence of food excites pain, which continues so long as the food remains in the stomach; carminatives or stimulants, so far from affording relief, aggravate the distress. In such cases the diet must be of the blandest and most unstimulating kind, and the amount of food rigidly limited. Restricting the patient to milk, diluted with an equal part of lime water, is sometimes attended by great benefit, and farinaceous articles are preferable to meat. In another and the larger class of cases, there is neither inflammation nor irritation present, but the powers of the stomach seem enfeebled; here stimulants relieve the distress, and cause at least a temporary improvement. In such cases a meat diet agrees better than an exclusively farinaceous one, and the patient is benefited by the use of the bitter tonics, colombo, gentian, quassia, &c. Certain remedies are adapted to the relief of particular symptoms; acidity is relieved by the use of alkalies and the alkaline earths; pain, by bismuth and hydrocyanic acid; flatulence, by carminatives; and constipation, when it cannot be obviated by diet and attention, may call forth the use of some of the purgative mineral waters, or of small doses of aloes in combination with nux vomica. It is in these cases that travel, combining as it does relaxation with mental excitement and exercise, is particularly serviceable.

E

E, the 5th letter and 2d vowel of the Latin alphabet, and of those derived from it. It is both short and long, and in the Greek alphabet has 2 corresponding forms, Εψιλον (slender E), the 5th letter, and Ητα (long E), the 7th letter (but counting 8 if the stigma be included). The short and long O, Ομικρον and Ωμεγα, are analogous to them. Simonides is said to have formed the H (ητα) by doubling the E (εψιλον), thus ΕΞ, the epsilon having before been both short and long. The H, however, was made by the Latins an aspirate, and was employed to represent the rough breathing, and the aspirate sound in Θ, Φ, and X, as *Homerus*, *Thales*, *Philon*, *Charon*. The prototypes of the aspirated Greek letters in question are the Phœnician and Hebrew *He* and *Chet*. Indicating the most fleeting sound of the human voice, a mere breathing in many cases, the letter E is the basis of the vowel system, and the most protean of all the vowels, as regards its shades of sound, its convertibility, the modes in which it is indicated in writing, and the uses that are made of it in various graphic systems. But few of its peculiarities can here be pointed out. In English it has 5 sounds, called long, short, open, obtuse, and obscure, respectively as in *mete*, *met*, *there*, *her*, and *brier*. The long English sound corresponds to the French and German I, while the French nasal E in *em* and *en* sounds like the English *a* in *swan;* and the sound of the French sharp E is represented in English by *a*, *ai*, *ay*, or *ey*, as in *made*, *maid*, *say*, and *they*. In Hebrew, it has 2 sounds; the open is noted by Tsere (break), or 2 horizontal dots under the consonant; the close by Segol (grape), or 3 dots, and 2 Sheva (emptiness), or 2 vertical dots, the one movable (half mute), the other quiescent (mute). The long E is written AI in Mœso-Gothic. In Greek the long and short E (ε and η) are both either open or close, but the latter is pronounced as I in Neo-Hellenic, Coptic, and Slavonic. In German it has 3 sounds, very short in *hatte*, *hoffen*, like the English short E in *Engel*, *rennen*, and like the English long A in *geben*, *predigen;* in Magyar 3, as in *emberiség*, humanity; in Italian and Spanish 2, the open and close; in French 6, viz.: open in *fête*, *il cède*, half open in *nous fêtons*, sharp in *été*, *parlez*, nasal in *bien*, half mute in *je*, *le*, *Breton*, and almost mute in *simple*, *sucre*, and is quite mute in *la rue*, *j'avouerai*. Both in English and French it influences preceding syllables by lengthening and changing their vowels; thus compare *made*, *mete*, *pine*, *note*, and *tube*, with *mad*, *met*, *pin*, *not*, and *tub*; and *il plane*, *il mène*, *fine*, and *une*, with *le plan*, *il ment*, *fin*, and *un*. In German it produces the metaphony of A, O, U, into Ä, Ö, Ü, as in *Männer*, men, *Vögel*, birds, *Hüte*, hats. It also lengthens vowels immediately preceding, as in Germ. *See*, sea, *dieser*, this, Eng. *true*, and Fr. *la vie*. It is very often elided, absorbing and absorbed; the elision is in many languages recorded by the sign of apostrophe; thus: *John's house*, *wish'd*, *l'homme*, and *l'erbe*. It is often a euphonic means for facilitating the utterance of words, as in *establish*, *établir*, *establecer*, *épice*, *espiritu*, *esprit*, *escribir*, *écrire*, *estado*, *état*, *estrella*, *étoile*, *Estevan*, and *Étienne*. It is prefixed for other reasons in εκεινος, *ecquis*, and many other

words. In Slavic languages it often coalesces with J, forming a sort of consonant; thus, *jest* (pronounced *yest*), Lat. *est; nie*, Lat. *ne, non.* E frequently occurs instead of I in ancient Roman memorials, as, for instance, on the *columna rostrata* of Duilius, on the tomb of the Scipios, and in the works of writers; thus, *sebe, quase, maecester, fuet*, for *sibi, quasi, magister, fuit.* In the Slavonic it occupies, as *jest*, the 6th place of the Bukvitsa as well as of the Cyrillic scheme, and has two softening forms as finals (*-er, -eri*) toward the close of the alphabet.—We give a promiscuous list of the substitutions or metaphonies of E, long and short, in different languages, resulting from glossic, dialectic, grammatic, euphonic, and other exigencies: τρεπω, τραπον, τροπος; λεγω, λογος; νεος, *novus*; πληγη, *plaga*; πατηρ, Ευπατωρ; Σικελος, *Siculus*; νεφος, *nubes*; κερας, *cornu*; *ago, egi*; *frango, fregi*; *facio, feci, effieio, fingo, fungor*; *pars, expers*; *bonus, bene*; *velle, volo, vis, vult*; *castus, incestus*; *vos, vester*; *sero, satus*, Eng. *sown, son*; *verto, vortex, adversus*, Eng. *toward*; *vermis, worm*; *audio, obedio*; *arista*, Germ. *Aehre*, Eng. *ear* (of corn); *fallo, fefelli*; *halo, anhelo*; *tego, toga*; *percello, perculi*; *vas*, Eng. *vessel*, Fr. *vaisseau*; *pes*, Eng. *foot, feet, fetter*, Fr. *pied*; *Anglia, England*, Ital. *Inghilterra*; *Cornelia*, Ital. *Corniglia*; *urbs vetus*, Ital. *Orvieto*; *decem*, Ital. *dieci*; *sequitur*, Span. *sigue*; *mecum*, Span. *conmigo*; *deus*, Span. *dios*; *nego*, Span. *niego*; *brevis*, Prov. *brieu*; *petra*, Wal. *peatre*; *sensus*, Portug. *siso*; *cera, ecclesia, racemus, ego, neptis*, Fr. (respectively) *cire, église, raisin, je, nièce*; *bene, mel*, Fr. *bien, miel*; *mensis, me*, Fr. *mois, moi*; Eng. *apple*, Iceland. *epli*; *aper*, Germ. *Eber*, Eng. *boar*; Eng. *man, men*, to *mean, mind*; *sell, sale, sold*; *enquire, inquire*; *fed, fat, feed, food*; *shed, shut*; *set, sit, sat, seat, site, sod*; Fr. *venir, vieus, vint*; Germ. *werden, ward, wäre, wird, wurde, würde, geworden.*—The figure of E is supposed by the abbé Moussard to be the base of the nose, ᚿ, its sound being symbolic of breathing, and hence of life. It has this or a similar shape in Phœnician, Hebrew, Samaritan, the ancient Italic alphabets, Idalian (Cyprian), and in their derivative systems. Court de Gébelin derives its form from the outline of the human face, which is a symbol, according to him, of the idea of existence. Dammartin pretends to have found its prototype for all graphic systems, including even the Chinese, in the southern triangle, and the bow of the constellation of the archer. It is represented by the *Stungen Ies* (*Stung* or pointed I) of the runic writing; its hieroglyphs are palm leaves or long feathers; the hieratic figure of it is a sort of tetragonal convolute, and the demotic is sickle-like.—Barrois asserts that E signifies one, since it is the initial of the Greek ἑις. As an abbreviation, E. stands for Ennius, *eques Romanus, egregius, emeritus, ergo, editio*, east, electricity, and excellence. The letters *d. e. r.* stand for *de eâ re*; *q. e. d.* for *quod erat demonstrandum*; *e. g.* and *c. c.* for *exempli gratiâ* and *exempli causâ.* In syllogisms, A = *asserit*, E = *negat.* On French coins it designates Tours; on those of Austria, Carlsburg in Transylvania; on those of Prussia, Königsberg. In Greek, E has the value of 5, and with a mark below it, of 5,000. According to Baronius, it represented the number 250 in the period of the decline of classic literature.—In music, it denotes the 3d great interval in modern musical nomenclature, or the 5th string in the chromatic scale, and is called *mi* in vocal music.

EACHARD, John, an English divine, born in Suffolk in 1636, died July 7, 1697. He studied and took his degree at the university of Cambridge, and became known by his satires against the clergymen of his time, making the sermons of his own father sometimes serve to give point to his ridicule. After becoming a clergyman himself, he wrote upon the "Grounds and Occasions of the Contempt of the Clergy and Religion," which he attributed to the insufficient salaries of clergymen, and the consequent necessity for them to eke out a living by unbecoming means. The work passed rapidly through 6 editions, and drew down upon its author abundant criticisms. He published 2 dialogues upon Mr. Hobbes's "State of Nature," in which he attacked the ideas of that philosopher in a humorous and vigorous way. An edition of his works, with a life, was published in 1714, and it is remarked by Warton that his writings must have been diligently studied by Swift.

EADMER, or Edmer, an English monk, the friend and biographer of Saint Anselm, died in 1124. He was chosen in 1120 bishop of St. Andrew's, in Scotland, but the Scottish king refusing to allow his consecration by the archbishop of Canterbury, and thus to admit the primacy of that see, he either declined the bishopric or abdicated it after a short possession, and died as a monk of Canterbury. Beside his life of Saint Anselm, contained in most of the editions of Anselm's works, he wrote the lives of Wilfred, Dunstan, and other English saints, a treatise on the "Excellence of the Holy Virgin," and on the "Four Virtues which were in Mary;" but his most valuable work is the "History of his own Times," an account of the principal events that happened in England and in the English church from 1066 to 1122 (best edition by Selden, 1623).

EAGLE, a bird of prey, of the order *aceipitres*, family *falconidæ*, and subfamily *aquilinæ.* The eagles have a strong bill, elevated at the culmen, straight at the base, and much arched to the tip, which is hooked and sharp; the sides are compressed, and the lateral margins festooned; the nostrils are in the cere, large; the wings are long and acute, the 3d, 4th, and 5th quills usually the longest; the tail is long, ample, mostly rounded at the end; the tarsi are long, either clothed with feathers to the base of the toes as in the golden eagle, or naked and covered with scales as in the bald eagle; the toes are long, strong, armed with large, curved, and sharp claws. In the type genus *aquila* (Mœhr.) belongs the golden eagle of Europe and America (*A. chrysaëtos*, Linn.). The length of this magnificent

bird is about 3 feet 2 inches, the extent of wings 7 feet, the bill along the back 2¾ inches, the tarsus 4½ inches, and the middle toe and claw the same; the bill is very robust, angular above; the head is moderate, the neck short, and the body full; the tarsi are feathered to the toes, and the feet are very stout; the middle toe has a membrane at the base connecting it with the others. The above dimensions are those of an adult female, the male being considerably smaller, in conformity with the rule that in birds of prey the females are larger than the males. The plumage is compact, imbricated, and glossy; the feathers of the neck and head are narrow and pointed, and may be erected like a short crest; the tail consists of 12 broad feathers. In the adult the bill is black at the tip, bluish gray at the base, the cere and margins yellow; iris chestnut; toes bright yellow, claws black; general color of the plumage dark brown, glossed with purple; the hind head and neck light brownish yellow, the feathers with dark shafts; the wing coverts light brown; primaries brownish black; tail rounded, dark brown, lighter at the base, irregularly marked with whitish; lower tail coverts, feathers of legs and tarsi, yellowish brown. The immature bird is of a deep brown color, with the tail white at the base for ¾ of its length, and dark at the end; this is the ring-tailed eagle of Wilson and others; the adult, from its majestic appearance, is called in Europe the royal eagle; the American species is considered distinct by some, and is called *A. Canadensis* (Linn.). The golden eagle is rarely seen in the eastern portion of the United States, though specimens have been obtained in all the northern states; a few years since a young bird was shot in Lexington, Mass.; the species is most common in the north-west, on the upper Mississippi, and in the mountainous regions of the country; it is also found in the cold and mountainous districts of northern Europe and Asia. The flight is powerful, though less rapid than that of the bald eagle, being continued for hours in majestic circles at a great elevation, and without apparent exertion; its prey is not seized on the wing, but is pounced upon on the ground from a great height with rarely failing precision. Its food consists of young fawns, raccoons, hares, wild turkeys, and birds and animals of similar size, and, when hard pressed by hunger, of carrion; capable of going several days without food, it gorges itself when opportunity offers. Its strength is great, and its weight about 12 lbs.; it is able to withstand extreme cold, and pursues its prey in the most violent storms. The voice is harsh and screaming, and very loud at the breeding season. The plumage does not attain its full beauty until the 4th year; the American Indians are fond of using the tail feathers as ornaments for their persons, pipes, and weapons. The nest is of large size, consisting of a rude collection of sticks, and placed on some inaccessible cliff; the eggs are generally 2, of a dull white color, with brownish shades, 3½ inches long and 2½ in diameter at the widest part; they are laid in February or March; the young, when able to provide for themselves, are driven from the eyry by their parents. This bird is long-lived, individuals, it is said, having been kept in captivity for more than a century. Though the eagle holds among the feathered race a position equivalent to that of the lion among beasts, being king of birds as the latter is the monarch of mammals, he belongs to the section of the ignoble birds of prey, which cannot be employed in the noble sport of falconry; in proportion to their size, the eagles are less courageous, and less powerful in beak, wings, and talons, than the falcons. The noble nature of the eagle, like that of the lion, is mostly a creation of the imagination, founded on external characters which have no corresponding internal qualities; he follows the instinct of his carnivorous nature, without regard to surrounding weaker animals, attacking where he is sure of victory, gorging himself like a glutton, patiently bearing forced abstinence from food, and at last soiling his royal beak with the foulness of carrion; the king-bird and the shrike are far his superiors in bravery, and all the qualities which have been specially assumed for him can be found in greater perfection in many common birds, beside many of the softer traits of character which find no place in his royal constitution; like most other kings, he has his superiors in many of the lowest of his subjects. The eagle is monogamous, and the mated pair are generally not far from each other; the same nest is used for many successive years. The scent of the eagle is feeble, but his sight is exceedingly keen; able to gaze at the sun at noonday, and rising toward it until beyond human sight, he can detect in the plains below his living prey. Like the condor, the eagle has been accused of carrying off little children to its nest, but such instances in both birds must be very rare, though doubtless they may have occurred. Another species of this genus is the spotted or rough-footed eagle (*A. nævia*, Gmel.), smaller than the golden, of a brownish color, with black white-tipped tail, and wings yellow spotted; it is found in the mountains of central and southern Europe and northern Africa, and preys upon the smaller animals.—In the genus *haliaëtus* (Sav.) belong the fishing or sea eagles, the best known and largest of which is the bald or white-headed eagle (*H. leucocephalus*, Linn.); the bill is 2¾ inches long, very robust, convex above; the head is large, and flat above; neck short and thick; body large, wings long, and tail rounded; the tarsus only 3 inches long, bare for its lower two-thirds and covered with large scales; the feet are short and robust, and the toes are free, rough, and tuberculous beneath, with very sharp curved claws. The plumage is compact and imbricated; the feathers of the head, neck, and breast are narrow and pointed, and of the other parts broad and rounded; there is a bare space between the bill and eye with a few bristly feathers; the eyebrows are bare and very prominent. In the adult the bill, cere, iris,

and feet are yellow, the first 3 being often almost white; the general color of the plumage is chocolate-brown, the feathers with paler margins; the head, greater part of neck, tail and its coverts, white; the quills are brownish black, with lighter shafts. The length is about 3 feet, and the extent of wings 7 feet; the female is somewhat larger. In the young bird the bill is black above, bluish gray at the end of the lower mandible; the feathers, which are white in the adult, are dark brown like the rest of the plumage, margined with lighter; the head and tail become white between the 3d and 10th year, according to circumstances of locality and captivity. It is very generally distributed over North America, on the sea-coast and in the interior; it has been found breeding from the fur countries to Florida. Its usual food is fish, which it procures easily, and for seizing and retaining which its sharp curved claws and rough feet are admirably adapted; but it eats the flesh of animals when it can get it, and often seizes small quadrupeds and birds of inferior flight; it has been accused of attacking children, and when pressed by hunger will feed on decaying carcasses. Strong, powerful in flight, free and independent in its habits, and noble in aspect, the bald eagle has been adopted as the emblem of the United States. Audubon, in his "Ornithological Biography" (vol. i. p. 161), gives a graphic description of the capture of a wild swan by the bald eagle; water fowl of smaller size are also taken by these birds hunting in company, and alternately pouncing upon the prey as it emerges from the water; young pigs, lambs, fawns, and poultry are greedily devoured; and the disgusting food of the vultures and carrion crows is often shared with this eagle. This representative of American prowess, though occasionally catching fish for himself, forces the fish hawk to obtain his favorite food for him in the following manner: when the fish hawk follows the shoals of fish in the rivers in spring, the eagle sits watching from the top of a tall tree; as soon as the former rises with a fish, and bends his course for the shore to devour it, the latter mounts above him, and by most unmistakable signs forces him to give up his prey to save his own life; the eagle closes his wings, drops down with great quickness, and seizes the fish before it reaches the water; and this marauding and mean career the eagle pursues till the migrations of the fish cease, and the fish hawks depart. The flight of this bird is very majestic, accomplished by easy flappings; it sails along with extended wings, and, according to Audubon, can ascend until it disappears from view, without any apparent motion of the wings or tail; and from the greatest heights it descends with a rapidity which cannot be followed by the eye. All authors are agreed as to the cowardice of the eagle when it is suddenly surprised or meets with unexpected resistance; a game cock put into a cage with a full-grown male at once attacked the eagle and beat him in the most approved manner, and even the common cock has fairly put this cowardly bird to flight. The females are somewhat larger, braver, and fiercer than the males. When wounded, or irritated in captivity, it defends itself with beak and claws, striking with the latter, and beating furiously with its wings. Like the golden eagles, these birds live to a great age. They are generally seen in pairs, and the union appears to last for life, the two hunting and feeding together, and driving off other birds of the same species. Along the southern Mississippi, incubation commences in January; the nest is placed on the top of a tall tree, and not on cliffs like the golden eagle's; it is a rude structure, made of sticks, turf, weeds, and moss, measuring 5 or 6 feet in diameter, used year after year, and added to annually. The eggs are usually 2, of a dull white color. The attachment of the old birds to their young is great. The weight of the adult male is from 6 to 8 lbs., that of the female from 8 to 12. The flesh of the young is said to be palatable, having the taste of veal. Audubon laments that this bird should have been selected as the emblem of the United States, and quotes the following from one of Benjamin Franklin's letters: "For my part, I wish the bald eagle had not been chosen as the representative of our country. He is a bird of bad moral character; he does not get his living honestly." After alluding to his tyranny over the fish hawk, Franklin continues: "With all this injustice, he is never in good case, but like those among men who live by sharping and robbing, he is generally poor. Beside, he is a rank coward; the little king-bird, not bigger than a sparrow, attacks him boldly, and drives him out of the district. He is, therefore, by no means a proper emblem for the brave and honest Cincinnati of America, who have driven all the king-birds from our country, though exactly fit for that order of knights which the French call *chevaliers d'industrie*." The writer, having had under his care for several months a large pair of these eagles, has had ample opportunity to observe their habits; the female not only attacks and abuses the male, but stretches her wings to the utmost extent, attempting to cover with them every piece of food placed in the cage. The name of bald eagle is really a misnomer, as the head is as thickly feathered as in any species; the proper name is white-headed eagle.—The bird of Washington (*H. Washingtonii*, Aud.) was first described by Audubon ("Ornithological Biography," vol. i. p. 58), and seems not to have been seen by any other ornithologist; he first saw it on the upper Mississippi in Feb. 1814; a few years after he met with a pair near the Ohio river in Kentucky, which had built their nest on a range of high cliffs; 2 years after the discovery of the nest he killed a male which was the subject of his description; after this he saw two other pairs near the Ohio river. His reason for giving the name to the bird is thus stated by himself: "Washington was brave, so is the eagle; like it, too, he was the terror of his foes; and his fame, extending from pole to pole, resem-

bles the majestic soarings of the mightiest of the feathered tribe. If America has reason to be proud of her Washington, so has she to be proud of her great eagle." The flight of this is said to be different from that of the white-headed eagle, the former encircling a greater space, sailing nearer the surface of the earth, and darting upon its prey in a spiral manner. The bill was bluish black, with pale edges; the iris chestnut-brown; upper part of the head, hind neck, back, scapulars, rump, tail coverts, and posterior tibial feathers, blackish brown, with a coppery gloss; the throat, fore neck, breast, and abdomen light brownish yellow, each feather blackish brown in the centre; wing coverts light grayish brown, those next the body approaching the color of the back; primaries and tail dark brown; anterior tibial feathers grayish brown. The length is given at 3 feet 7 inches, extent of wings 10 feet 2 inches, bill 3¼ inches, tarsus 4½ inches, and the weight 14½ lbs.; this was a male, and of course the female would have been considerably larger. Though this bird is generally admitted as a species on the authority of Audubon, many ornithologists do not regard it as such. The characters of the bill and color of the plumage are very like those of the young white-headed eagle; the increase in length is only 3 or 4 inches, while the increase in extent of wings is about 3 feet, which proportions throw some doubt on the accuracy of the measurements, as such a relative extent of wings belongs rather to the vultures than the eagles. It is very strange, too, that no other ornithologist should have been able to see or procure this bird, and that no specimen should exist in any cabinet. It does not appear that Audubon came very near the eagles which he calls "birds of Washington," except in the instance in which he shot one, which from his drawing and description might very well be a young white-headed eagle; in the other cases they were flying over him, except when he watched them from a nest at a distance of 100 yards, which certainly is not near enough to form a sufficiently accurate idea even of so large a bird as an eagle. The fact of the nest being on a cliff is in favor of their having been golden eagles, as the white-headed species builds in lofty trees. There seems, therefore, sufficient ground for doubting the validity of this species, which ought not to be acknowledged until further proof is given of its non-identity with the golden, the white-headed, or perhaps the white-tailed sea eagle of Europe; it seems to have some of the characters of all these, united to the wings of a vulture, which would place it, if a reality, in a genus distinct from *aquila* or *haliaëtus*.—The white-tailed or cinereous sea eagle of Europe (*H. albicilla*, Linn.), the young of which Audubon thinks bears the greatest resemblance to his bird of Washington, has at this age a blackish bill; head and hind neck dark brown, with white markings, disappearing with age; fore neck and breast brown, with brownish white marks; general color of the plumage light brown, with a dark streak on the middle of each feather. In the old bird the bill becomes yellow, the general plumage grayish brown, palest on the head and neck, and the tail white; the length is 3 feet, and the extent of wings 6 feet 9 inches. This species, called also osprey, ossifrage, and pygargus, is distributed over the northern portions of the old world; it feeds principally on fish, like our white-headed eagle, forcing the fish hawk to provide for him on the principle that "might makes right." It prefers cold climates, and the vicinity of the sea, though it visits the interior rivers and lakes; when unable to obtain fish, it feeds upon sea birds, young seals, and any small animals which it can surprise. Its flight is neither so elevated nor so rapid as that of the previously described species. The nest is placed on cliffs near the sea, and the eggs are 2, of a dirty white color; incubation takes place in April.—The northern sea eagle (*H. pelagicus*, Pallas) is the largest of the family, and inhabits the Russian American islands and northeastern Asia. The total length of the female is 3¾ feet; the wings are shorter than usual, and the tail is wedge-shaped. In the adult the bill and the legs are yellow; the general plumage brownish black, with a large frontal space, greater wing coverts, abdomen, and tail, white. In the young the tail is white, with brownish black marks, the quills black, the secondaries and tertiaries white at their bases; other parts dull brownish black. It is a fishing eagle, though it occasionally captures birds and quadrupeds. According to Pallas, it breeds in northeastern Asia.—There are several genera of smaller eagles, as the crested eagles (*spizaëtus*, Vieill.). The black-tufted eagle (*S. ornatus*, Daud.) is as large as a raven, black, with a long tuft hanging from the occiput, and the edge of the wings and bands under the tail whitish; the crest is mixed with white; the thighs and tarsal feathers banded with black and white; tarsus feathered to the toes; it inhabits South America. Other species of the genus are found in Africa and the Indian archipelago, where they live in jungles and woods, pouncing on pheasants, hares, and similar animals passing underneath; they also seize prey on the wing. The reptile eagles (*morphnus*, Cuv.) are peculiar to South America; they live in the forests, feeding on reptiles, small animals, and birds. A well-known species is the *M. urubitinga* (Gmel.); this is black, without a crest, rump and lower part of the tail white; the long tarsi are bare of feathers. The harpy eagles (genus *thrasaëtus*, Gray, or *harpyia*, Vieill.) are peculiar to South America; they will be described in the article Harpy. The genus *pandion* (Sav.) will be described under Fish Hawk, the common name of the best known species. The caracara, or Brazilian eagle, does not belong to the *aquilinæ*, but to the *polyborinæ*, a subfamily coming nearest to the vultures; this bird (*polyborus tharus*, Molina) is of various shades of brown, with streaks and mottlings of

brownish black; wings barred with white, and the tail coverts dull white barred with dusky; tail grayish white, with 16 narrow bars and a terminal band of blackish brown; the length is about 2 feet, and the extent of wings 4 feet, the bill 2¼ inches. It is found from Florida to Brazil, and it feeds with the turkey buzzards and carrion crows on carcasses; it has the habits of the vultures, with the additional power of carrying prey in its talons; beside carrion, it devours small reptiles and birds; it walks like the turkey buzzard. Its flight is rapid and graceful.—The eagle, in mythology, is the sacred bird of the Hindoo Vishnu and of the Greek Zeus. In the Roman ceremony of apotheosis an eagle ascended from the burning catafalco, and was believed to bear the soul of the deceased to Olympus. In the Scandinavian mythology, it is the bird of wisdom, and sits in the boughs of the tree *yggdrasill*.—The Etruscans were the first who adopted the eagle as the symbol of royal power, and bore its image as a standard at the head of their armies. From the time of Marius it was the principal emblem of the Roman republic, and the only standard of the legions. It was represented with outspread wings, and was usually of silver till the reign of Hadrian, who made it of gold. The double-headed eagle was in use among the Byzantine emperors, to indicate, it is said, their claim to the empire both of the East and the West; was adopted in the 14th century by the German emperors, and afterward appeared on the arms of Russia. The arms of Prussia were distinguished by the black eagle, and those of Poland by the white. The eagle is the emblematic device of the United States of America, is the badge of the order of the Cincinnati, and is figured on coins. Napoleon adopted it for the emblem of imperial France; it was not, however, represented in heraldic style, but in its natural form, with the thunderbolts of Jupiter. It was disused under the Bourbons, but was restored by a decree of Louis Napoleon (Jan. 1, 1852). The order of the white eagle was created in Poland by Ladislas the Short, in 1325, was renewed in 1706, and since 1831 has been united with the imperial orders of Russia. The order of the black eagle was founded in 1701 by Frederic I., the first king of Prussia, and is conferred upon princes of the royal family, members of foreign sovereign houses, and a few officers of state, to whom it gives personal nobility. The order of the red eagle, the second Prussian order in dignity, was founded in 1712 by the margrave George William of Baireuth, and was transferred with that principality to Prussia in 1792.

EAGLE, a gold coin of the United States, of the value of $10, first coined in 1795, as provided by the act of congress of April 2, 1792, of the fineness of 22 carats (916⅔ thousandths), and weighing 270 grains, thus containing 247½ grains of pure gold. The silver dollar contained at the same time 371¼ grains pure silver, the ratio of valuation of silver to gold being as 15 to 1. An ounce of pure gold being worth more than 15 of silver in Europe, our gold coins continued to be exported until the act of June 28, 1834, substituted the ratio of 16 to 1 by reducing the fineness of the eagle to 899 $\frac{2}{10}$ thousandths, and its weight to 258 grains, being 232 grains pure gold. By the act of Jan. 18, 1837, the fineness of the eagle, as of all the other coins, was raised to 900 thousandths, its weight remaining as before 258 grains, of which 232 $\frac{32}{100}$ were pure gold; and at these rates it continues to be coined.—There are also a half eagle, first coined in 1795, a quarter eagle, first coined in 1796, and a double eagle, first coined in 1849.

EAR, the organ of hearing. Anatomists divide it into the external, the middle, and the internal ear. The first consists of the visible external organ, a cartilaginous and fleshy structure, of the form best adapted to collect the atmospheric vibrations, and the meatus or tubular opening leading to the tympanum. The *tympanum* is a firm fibrous membrane stretched across this opening, whose office, as its name implies, is to communicate vibrations like the head of a drum. The middle ear is a cavity about the form and size of a kidney bean; from its lower point a tubular opening descends to the posterior part of the mouth, and terminates in a trumpet-like expansion; this is usually called the Eustachian tube, and sometimes *meatus auditorius internus*. Across the middle ear is stretched a chain of 4 minute bones, connected with each other by cartilage and tendon. These are the *malleus* or mallet, the *incus* or anvil, the *orbicularis* or round bone, and the *stapes* or stirrup, each named from some fancied resemblance. The office of this chain, which is attached to the tympanum at one end, and to the membrane covering the *foramen ovale* at the other, is to transmit the vibrations of the air; to and in this, they are controlled by 2 minute muscles, which render the 2 tympani tense. The whole of the middle ear, with these minute bones, is covered with mucous membrane, and when irritated, as by a cold, it secretes mucus very freely, and thus often induces temporary and partial deafness. The internal ear, also called the labyrinth, to which the external and middle ear are but the ante-rooms, consists of the vestibule, the 3 semicircular canals, and the cochlea. The vestibule is an irregular cavity shut out from the middle ear by the membrane covering the foramen ovale, and communicating with the semicircular canals by 5 openings, 2 of these canals being joined at one end. The *cochlea*, as its name implies, is a bony structure resembling in form a snail shell; internally it is divided by a lamina, bony, ligamentous, and muscular, into 2 cavities called the *scala vestibuli* and the *scala tympani*, which communicate at the top of the cochlea, in a curved channel called the *modiolus*. This modiolus has numerous orifices, through which pass the filaments of the auditory nerve. The whole internal ear is lined with a delicate serous membrane, which secretes a fluid called perilymph. Within the vestibule and the semicircular canals, we find the

membranous labyrinth; in the vestibule it consists of 2 membranous sacs, one called the *utriculus*, and the other the *sacculus*, communicating with each other and extending in slender tubes through the semicircular canals, of which they only occupy about one-third; in the vestibule and modiolus, these sacs receive the nervous filaments, and are thus connected with the serous membrane lining the labyrinth, but everywhere else they are free, and separated from it by the perilymph, while their internal surfaces secrete a similar fluid called endolymph. In the vestibular portion is found a crystalline powder, proved by chemical experiment to be carbonate of lime, and denominated *otolithes;* the office of this is supposed to be to communicate the vibrations to the nervous surfaces. The filaments of the auditory nerve terminate by loops, or minute points, in the sacculus, the utriculus, the *ampullæ* (the little membranous tubes which pass through the semicircular canals), and the lamina which divides the cochlea. In the process of hearing, the vibrations of the atmosphere, caused, we will say, by touching one of the keys of a piano, pass toward the ear, where they are collected and concentrated by its peculiar form and structure; thus concentrated, they pass along the canal to the tympanum, where they produce a vibration; this vibration is communicated by the little chain of bones we have described to the membrane covering the foramen ovale, by which it is passed to the fluid contents of the vestibule and to the sacs, and by the agitation of the otolithes it is transmitted to the nervous surface, which is expanded over the whole labyrinth, and produces the sensation of sound. The internal and middle ear are situated wholly within the temporal bone, which is here much thicker and harder than elsewhere, in order to protect the delicate and complicated structure from injury.—Under the head of Deaf and Dumb we have spoken in general terms of the causes which induce deafness; but we may say here that while congenital deafness is usually the result of deficiency or malformation of some portion of the organ, thus preventing the transmission of the vibration or sound wave, accidental deafness usually arises from perforation of the tympanum by ulceration or otherwise; mucous secretion, the result of inflammation, clogging or thickening the membranes of the middle ear, or ulceration attacking the little bones and causing their discharge; inflammation of the serous membrane of the labyrinth, or paralysis of the auditory nerve. As may be supposed, the cure of complete deafness is exceedingly rare, and most of the cases reported will be found on examination either not to have been cured, or not to have been of persons entirely deaf.—The sense of hearing, like most of the senses, is capable of a much higher cultivation than is generally given to it. The blind, to whom touch and hearing make up in part for the loss of vision, acquire remarkable powers of hearing. They will hear a footstep or the opening of a door, at a distance at which ordinary persons cannot distinguish a sound. The Indian, too, possesses extraordinary powers in this respect; applying his ear to the earth, he will discover the approach of an enemy, and obtain some idea of his numbers, long before the eye can detect his coming. In almost all brain affections, there is more or less morbid sensitiveness of hearing; and in that condition of the nervous system brought on by long continued and intense excitement, and which often terminates in insanity, the same phenomenon is observed.—The form of the external ear varies materially in different races of men, and still more in the animal tribes. In the Caucasian race it is of moderate size, well formed, and neither very prominent nor pressed closely to the head. In the Malay and Mongolian it is large, ill proportioned, the lobe naturally long, and the whole ear standing out prominently; in the Indian race the conformation is similar to the Mongolian, though less prominent; in the negro the ear is flat, broad, and adheres so closely to the head as to give the idea of having been fastened there by a bandage. Of the inferior animals, the mammalia only have an external ear; in birds it is merely a small orifice; in fishes, when it exists, it is covered by the skin, as it is also in reptiles. The variety in its form in mammals extends even to different varieties of the same animal. The drooping ear of the King Charles and other spaniels contrasts forcibly with the erect prominent ear of the foxhound and the Esquimaux dog; and both differ greatly from the short open ear of the bull-dog. The horse has a sensitive and well formed ear, though of small size; while the ass, with no better powers of hearing, is supplied with long aural appendages which seem most adapted for fans. The elephant has a small ear as compared with his great size, though the flap of skin which protects it is of considerable dimensions. The carnivora generally have small but very quick ears, and they usually possess erectile power which enables them to throw them into shapes in which they will most readily catch the sound wave. The mole, though his ear is hardly discernible in the fine fur which covers it, is yet very quick of hearing. Of all the mammals, the bat tribe possess the largest ears in proportion to the size of their bodies, the *phyllostonus* and the *megadenus* in particular being provided with these appendages so large as to form nearly $\frac{1}{3}$ of the superficial extent of their bodies. Among savage and half-civilized tribes the idea prevails that the lengthening of the lobe of the ear by heavy ornaments, and the enlargement of the perforations made for attaching them, both add greatly to the beauty of the wearer. In the Burmese statues of Gaudama, he is represented in a sitting posture, and the lobes of his ears extend to the level of his lap. Among the African tribes the perforation in the ear is enlarged so that a stick an inch or more in diameter may be thrust through it, and some of them use the ear instead of a pocket to carry small articles.

EAR RINGS, a kind of ornament common both among savage and civilized peoples. They are alluded to in the earliest literature of both Asia and Europe, and are found represented upon remnants of sculpture older than any literature. They have been discovered amid the ruins of Thebes, in the tombs of Egyptian kings, and have been dug from Herculaneum, Pompeii, and Nineveh. Abraham, the father of the Hebrews, sent them as a present to his son's wife; Alexander, when he marched to the East, met with them in Babylon, and on the banks of the Indus; Cortes found them in use among the wealthy Mexicans; among the Greeks and Romans they were equally worn by noble ladies and serving maids; and in the later Christian civilization they have enjoyed a nearly universal prevalence. They are termed rings in the Hebrew and other ancient as well as the English and other modern languages, and their original form was doubtless a simple circlet. Among the oriental nations, the Hebrews excepted, they were worn by both sexes, and though at first of gold or silver, were subsequently made with agate, chalcedony, onyx, coral, and pearls. They were sometimes single hoops of gold from 1½ to 3 inches in diameter, but were more frequently jewelled drops or pendants of various styles, hung from a small ring inserted in the ear. Even at the present day the finest ear rings in the world are in the harems of the East, and European princesses in devising this ornament have been unable to excel the taste of Persian maidens and of the slaves of the sultan. The use of ear rings among the Greeks and Romans was confined chiefly to women. The favorite style was a pendant, framed of gold and set with precious stones. Pearls were valued for being exactly spherical and for their delicate whiteness; and 2 or 3 of them were generally joined together to elongate a single drop, and 2 or 3 such drops were often suspended from a single ring. In the Iliad, Juno, adorning herself in her richest and most captivating attire, puts on ear rings made with 3 drops resembling mulberries; and in the Odyssey the splendid present which Eurydamus sends to Penelope is a set of ear rings of a similar style. The Venus de' Medici has the ears pierced, and probably there were once ear rings in them. At Rome the precious stones came especially into use for this ornament, and in the progress of luxury under the emperors the Roman matrons, according to Seneca, often carried suspended from their ears the worth of 2 or 3 rich patrimonies. The pendants were sometimes made to resemble a series of nuts, or were adorned with figures of centaurs or horses, or marine animals, and were so arranged as to vibrate against each other upon every motion of the head, and thus to produce a constant gentle tinkling. Instead of a ring, a hook was often used to attach the ornament to the ear, and the women of Italy still continue this practice, passing the hook through the lobe of the ear without any other fastening. One of the most famous of modern ear rings was the property of a Polish lady, and consisted of a series of diamonds, arranged so as to represent an acacia blossom, the setting being made to resemble a leaf of the same tree. The lotus blossom and the Bengal rose were sometimes copied in Egyptian and Indian ear rings, and the Chinese women wear ear rings resembling the fantastic flora of their country. Roman ladies of the highest rank sometimes wore this ornament in the shape of an asp, whose body was of gold set with precious stones; and among the women of South America it is often made to resemble a humming bird. Both among the ancients and moderns ear rings have sometimes borne miniature likenesses of friends. In recent times they have very generally been supposed to be beneficial to the health, and especially to be a protection against weakness of the eyes, and in this belief they are still frequently worn by men in France and Italy, and sometimes also in the United States, and are common among boys in Germany.

EAR TRUMPET. Under this title may be included all those contrivances intended to aid the hearing of persons partially deaf. We have no means of ascertaining at what period or by whom ear trumpets were invented. The practice of putting the hand to the ear in a trumpet shape probably first suggested it, and from occasional allusions to the use of the trumpet in old writers it would seem to have been of very early origin. The earliest form of which we have any knowledge was a rude imitation on an exaggerated scale of the form of the external ear; but as this was found inconvenient from the difficulty of retaining it in place, a form more nearly resembling a speaking trumpet was substituted. As this again was found inconvenient from the space it occupied and the difficulty of supporting it in position, a curved form was substituted, descending from the ear close to the side of the face and presenting the trumpet-shaped mouth upward. Another modification was a flat tube passing over the head and applied to each ear, while in front and immediately over the forehead was an opening to receive the sound. Another inventor, having observed that in listening intently people opened their mouths, contrived a sort of plectrum or vibrating body to be held between the teeth, and thus to convey sounds by the Eustachian tube. After the introduction of caoutchouc and gutta percha into the arts, a long tube of one or other of these materials, with a bell-shaped trumpet at the end, took the place of the metallic trumpet, and for many purposes is very convenient. In England in some of the churches pews are constructed with tubes to conduct the sound, opening in convenient positions for the ear of the listener. Among the more recent inventions for facilitating hearing are the auricle, a small tube of silver with a semiglobular expansion, intended to be inserted into the meatus of the ear; and the tympanum, a small thin disk of rubber, having a silver wire passing through it to transmit the sound wave. In a few cases

the latter has been of considerable service. In cases of total deafness, no such means are of any advantage.

EARL, the most ancient title of nobility used in Great Britain. Under the early Saxon kings the powerful nobles to whose charge shires or territories had been committed were called *ealdormen*, literally elder men (whence the modern alderman), a term equivalent to the Latin *senior* or *senator*, and given in Latin documents as *princeps*, *dux*, or *comes*. The Danes subsequently applied the term *eorle*, which signified originally a man of noble birth, as opposed to the *ceorl* or churl, to the same men who had borne the title of *ealdormen*. The Saxon earl derived his title solely from his office, which was originally in the gift of the crown, and in recompense for his services received a part of the revenues of his province to his own use. Toward the close of the Saxon dynasty these provincial governors not only greatly enlarged their authority, but claimed the dignity as hereditary; and in the time of Edward the Confessor the whole kingdom was divided between 5 powerful earls, including Godwin and his sons Harold and Tosti, of whom Harold subsequently usurped the throne. After the Norman conquest the territorial possessions of the Saxon nobility were declared forfeited, and with many newly created fiefs were distributed among the chief followers of William the Conqueror, who thereupon assumed the name of counts, from the Latin *comes*. But this title was very soon replaced by the old one of earl, while the territory from which the new dignitary received his name or over which he exercised jurisdiction was thenceforth called a county, instead of a shire as previously under the Saxons, and the consort of the earl became a countess. According to Cruise, there were 3 sorts of earldoms under the early Norman kings: the first and highest, where the dignity was annexed to the possession of a whole county, with the *jura regalia*, in which case the county became a county palatine, and the person created earl of it exercised all the authority of a sovereign; the next, where the earl was entitled to the third part of the revenues of the county court; and the third, where a tract of land was erected into a county and granted with civil and criminal jurisdiction to be held *per servitium unius comitatus*. This statement, however, is open to controversy, and Sir Harris Nicolas is of opinion that the Norman earls, excepting in the counties palatine, possessed no jurisdiction over the counties from which they were denominated, the dignity being of a nature altogether personal. At present the title conveys no local jurisdiction or revenue, and is no longer confined to the names of counties, but may be derived from those of towns or villages, or of families. It remained the highest hereditary dignity in England until the reign of Edward III., when the first dukedom was created, and is now the 3d order of the British nobility, being next below that of marquis, and above that of viscount. After the barons the earls are also the most numerous of any order, numbering (in 1859) 234, of whom 47 have Scottish and 68 Irish titles. They are styled by the sovereign "right trusty and well beloved cousin," an appellation attributed to Henry IV., who had his own reasons for flattering the powerful earls, with nearly all of whom he is said to have been allied by birth or marriage, by frequent allusions to the relationship. They are now created by letters patent, in place of the old practice by which the sovereign girded on the sword of the new earl and invested him with mantle and coronet.

EARL MARSHAL, an officer of state in England, who directs important ceremonies, takes cognizance of matters relating to honor, arms, and pedigree, and proclaims the declaration of war or of peace. The office was established in the reign of Richard II., who conferred it upon Thomas Mowbray, earl of Nottingham, and is now hereditary in the family of Howard, the head of which, the duke of Norfolk, is the present earl marshal of England.

EARLE, PLINY, an American inventor, born in Leicester, Mass., Dec. 17, 1762, died there, Nov. 19, 1832. In 1785 he became connected with Mr. Edmund Snow in the manufacture of machine and hand cards for carding cotton and wool; and in 1790, when Mr. Samuel Slater, the originator of cotton factories in this country, was establishing his first factory at Pawtucket, he applied to Mr. Earle to furnish him with what are technically termed twilled cards, all the cards then manufactured in this country being plain. Mr. Earle at first made these by hand, but soon invented the machine still in use for their manufacture, by which the labor of a man for 15 hours could be performed in as many minutes. Aside from his inventive genius, Mr. Earle deserves a record for his extensive attainments in science and literature.—PLINY, an American physician, son of the preceding, born in Leicester, Mass., Dec. 31, 1809. He was educated at the Friends' yearly meeting boarding school at Providence, R. I., where he was subsequently employed as a teacher. He received his diploma of M.D. in 1837, after which he spent 3 months in London and a year in Paris, and some 10 months more in travel, returning to Philadelphia in 1839. In 1840 he was appointed resident physician of the insane hospital at Frankford, Penn., under the care of the Friends, where he remained a little more than 2 years. In 1844 he was appointed physician to the asylum for the insane at Bloomingdale, N. Y., where he remained till April, 1849, when he visited the insane hospitals of England, Belgium, Germany, Austria, Poland, and a part of those of France. In 1847 he declined an appointment of visiting physician to the New York city lunatic asylum, but accepted it when again offered in 1853. He has been a somewhat voluminous writer, principally in the medical and scientific journals and the "Journal of Insanity." In 1841 he published a small volume of poems entitled "Marathon and other Poems;" but fear-

ing that they might endanger his professional standing, he withdrew the edition from the market very soon after its publication. The same year appeared his "Visit to 13 Asylums for the Insane in Europe." In 1848 he published the "History, Description, and Statistics of the Bloomingdale Asylum." After his return from his second European tour, he published in the "American Journal of Insanity" a series of articles on institutions for the insane in Germany and Austria, which were subsequently collected in a volume. Another series of articles on "Bloodletting in Mental Disorders" was also published in book form in 1854. His other contributions to the medical and psychological journals are very numerous. —THOMAS, a writer on law, brother of the preceding, born in Leicester, Mass., April 21, 1791, died in Philadelphia, July 14, 1849. His early education was obtained at the academy of his native town. In 1817 he removed to Philadelphia, and engaged in mercantile pursuits for a few years, and then having studied law commenced the practice of the profession in that city, where he was distinguished not only for legal ability, but for the large amount of time he bestowed without fee or reward in defending the cause of the poor, often refusing cases offering large pecuniary emolument in order to attend to those who were unable to pay. He edited in succession the "Columbian Observer," "Standard," "Pennsylvanian," and "Mechanics' Free Press and Reform Advocate;" and he took an active part in calling a convention to revise the constitution of Pennsylvania in 1837, was a prominent member of it, and is believed to have made the original draft of the new constitution. At this time he was so popular that any office in the gift of the people was at his command, but he lost the support of the party with which he was connected (the democratic) by advocating the extension of the right of suffrage to negroes. In 1840 he was the candidate of the liberty party for the vice-presidency. After that period he mingled little in political affairs, and devoted himself almost entirely to literary pursuits. His first published work was an "Essay on Penal Law," written while he was a member of the law academy of Philadelphia, and published by the library company. This was followed by an "Essay on the Rights of States to alter and annul their Charters," a work which elicited the approbation of Thomas Jefferson; a "Treatise on Railroads and Internal Communications," published in 1830; a spelling book for schools, which was highly approved by eminent teachers in Philadelphia and vicinity; a "Life of Benjamin Lundy," an eminent philanthropist. At the time of his death he had nearly completed a history of the French revolution and a translation of Sismondi's "Italian Republics."

EARLY, a S. W. co of Ga., bordering on Ala., bounded W. by the Chattahoochee river, and N. by Colamoka creek; area, 864 sq. m.; pop. in 1852, 8,641, of whom 4,211 were slaves. The surface is a fertile plain, watered by Spring creek and several of its branches, and occupied by corn and cotton plantations, interspersed with forests of oak and yellow pine. Scarcely a rock is to be seen in the county. The Chattahoochee is navigable along the border of the county by steamboats, and the smaller streams furnish good water power. On the bank of Colamoka creek is one of those remarkable ancient mounds which have been found in various parts of the United States. It is 75 feet high, with a level surface on the top 240 by 90 feet in extent. The productions of the county in 1850 amounted to 4,354 bales of cotton, 223,037 bushels of Indian corn, and 76,377 of sweet potatoes. There were 16 churches, 1 newspaper office, and 144 pupils attending academies and schools. Value of real estate in 1856, $994,031. Named in honor of Peter Early, governor of Georgia in 1813. Capital, Blakely.

EARLY, JOHN, a bishop of the Methodist Episcopal church south, born in Virginia in 1785. At an early age he joined the Virginia conference, and became an itinerant minister. He filled successively the offices of secretary of conference, presiding elder, and delegate of the general conference. At the general conference of 1846 he was elected general book agent, in which office he continued until elected bishop in 1854. As a traveller, revivalist, and systematic preacher, it is said of him that he has few equals in the ministry of the southern Methodist church.

EARTH, the planet upon which we live. (For its motions and its relations to the heavenly bodies, see ASTRONOMY.) The ancients, familiar with only a small portion of its surface, entertained the crudest notions of its form and extent. In the time of Homer it was regarded as a flat circle, everywhere surrounded by a dark and mysterious ocean. The nations which dwelt upon its borders were called Cimmerians and described as living in perpetual darkness. In every direction the most distant lands heard of were placed on the margin of this ocean, so that as geographical knowledge increased its shores in like manner receded. The strait at the pillars of Hercules, leading into the ocean, was for many centuries the boundary of the earth toward the west. The Black sea appears for a time to have been the boundary in the other direction, and Colchis on the margin of the Eastern sea. Ethiopia reached the sea to the south, and the Riphæan mountains stretched to the northern verge of the earth. The ancient Hebrews found the same boundary to the west; but in other directions they vaguely spoke of the "ends of the earth." Availing themselves of the commercial enterprise of the Phœnicians, they had in the time of Solomon prosecuted their trading voyages through the straits of Babelmandeb into the Indian ocean, bringing home from expeditions of 3 years' duration the products of tropical regions; while their ships sent westward toward the Atlantic returned laden with the tin, silver, lead, and other metallic products of Spain and Great Britain. The ex-

peditions of Alexander into Asia opened new countries in the east, and largely extended the geography of the Greeks. The Romans by their conquests added discoveries in the other direction; but these, while they removed further off, still served to fix the encircling ocean, the *mare tenebrosum*, as the impassable barrier and limit to the land. At a very early period the astronomers among the Egyptians, Chaldeans, and Greeks perceived that the heavenly bodies, while occupying the same positions, stood in different relations to different points upon the surface of the earth. In the school of Thales, Anaximander, Anaximenes, and Pythagoras, the sun dial was employed to mark the progress of the sun in its meridional range, and to determine the latitude of places, and the division of the year into 365 days. The length of the longest and shortest days at numerous places was determined by the Egyptians with this instrument, and they first added 5¼ days to the older division of the year into 360 days. Thales (born at Miletus, 640 B. C.) perceived the error of giving to the earth a plane surface, and ascribed to it a spherical figure and a position at the centre of the universe. Anaximander believed it was cylindrical; and in the Pythagorean cosmography the extraordinary advance was made of placing the sun in the centre of the system with the earth moving about it. But this step was soon lost, and the knowledge of the extent and form of the earth made but slow progress as the limited observations of travellers were gradually accumulated. A latitude observation is recorded of Meton and Enctemon at Athens, 432 B. C. As commercial intercourse was extended among the nations and navigation became an important art, the spherical figure of the earth must have become apparent by the same phenomena which are now commonly appealed to in proof of it, viz.: the sinking of distant objects seen upon a level plain, as the sea below the horizon; the greater or less elevation of the circumpolar stars, as the observer is further toward the north or the south; the different angles under which the sun is seen at noon of the same day at different points on the same meridian; and other appearances of the same character. This form being recognized, it was natural to seek the measure of its circumference, and it is extremely probable that attempts of this kind were made before any of those of which we have account. Some of the measures of the most remote antiquity appear to have relation to the terrestrial circumference; and, as stated by Laplace, they seem "to indicate not only that this length was very exactly known at a very ancient period, but that it has also served as the base of a complete system of measures, the vestiges of which have been found in Asia and Egypt." Aristotle states that before his time the circumference had been determined by mathematicians at 400,000 stadia. Eratosthenes, who lived the next century after Aristotle, appears to have been the first to clearly perceive the true method of applying astronomical observations to the measurement of a degree upon the surface of the earth, and from this to calculate the whole circumference. At Syene, in upper Egypt, was a well, at the bottom of which the full disk of the sun was seen at noon of the day of the summer solstice; at the same time from Alexandria, then taken to be on the same meridian, its angular distance from the zenith was 7° 12′. This was the measure of the celestial arc between the two zeniths, and bore the same relation to the whole circumference as the distance between the two points on the surface bore to the circumference of the earth. Presuming this distance to be 5,000 stadia, and 7° 12′ being $\frac{1}{50}$ of a circle, the total circumference was then 250,000 stadia. The world known by the reports of travellers extended only about 38,000 stadia in a N. and S. direction; and from the pillars of Hercules to the city of Thinæ upon the eastern ocean, along his base line drawn E. and W. across the Mediterranean, Eratosthenes reckoned a greatly exaggerated distance of 70,000 stadia, and yet less than $\frac{1}{3}$ of the whole circumference. He indulges only conjectures whether the remainder was occupied entirely by the ocean he called the Atlantic, or consisted in part of strange continents and islands. Posidonius next attempted a similar measurement by observations of the altitude of the star Canopus, when seen on the meridian at Rhodes, and again at Alexandria. Finding a difference of altitude of 7° 30′, and assuming the meridional distance of the two points to be 5,000 stadia, he made the whole circumference 240,000 stadia. Of the real value of the stadium employed we are entirely ignorant; and it is certain that it was not, as employed at that time, a fixed determinate measure. The great astronomer Hipparchus of Rhodes, born at Nice, in Bithynia, 140 B. C., first determined the longitudes of places upon the earth by the eclipses of the moon, and produced maps upon which localities were designated by their latitudes and longitudes. Thus a means was furnished of determining the relative positions of places without the necessity of measurements upon the surface between them; and afterward, when suitable instruments should be contrived, of finding directly any spot beyond the sea, and returning to the starting point. Adopting these principles, Ptolemy, the astronomer and geographer, prepared the most complete map of the world so far as it was known, designating places by their latitudes and longitudes, and causing the meridians to approach each other toward the pole. For want of accurate measurement of the length of a degree, his map, however, was very imperfect. Still it continued for many centuries to be the great authority in geography; and it was not until 1635, when the difference of longitude between Marseilles and Aleppo was found to be only 30° in place of 45°, as represented upon the map, it became apparent that more perfect observations for longitudes must be adopted than those of the ancients. The uncertainty of the results obtained by observing eclipses of the moon was soon perceived, and at

last the suggestion of Galileo was adopted of observing the eclipses of the satellites of Jupiter. In the 9th century an attempt was made by direction of the caliph Al Mamun, who reigned at Bagdad from 813 to 833, to determine the length of a degree of latitude. His mathematicians assembled on the plain of Shinar, and, taking the altitude of the polar star, separated in two parties, travelling in opposite directions till they found a difference of altitude of one degree. They made the distance upon the surface the same as that given by Ptolemy, probably adopting his conclusion, which they were set to verify. From this time to the middle of the 16th century no further attention was given to ascertaining the dimensions and true figure of the earth by astronomical observations; but vast accessions of geographical knowledge were made by the enterprise of the navigators of this period. They at last solved the mystery of the *mare tenebrosum*. The next attempt to determine the circumference was made by Fernel, a French physician, who died in 1558. In the want of exact surveys, by which the true distance between places might be known, he measured the space between Paris and Amiens by the number of revolutions of his carriage wheel, and making his observations for latitude he made the length of a degree 57,070 French toises; a remarkably close approximation to the actual length. Willebrord Snell, a mathematical teacher of Holland, made in 1617 a similar attempt between Alkmaar and Bergen-op-Zoom; and he was the first to apply a system of triangulation to expedite his geodetic measurements. His instrument for observing angles was a quadrant of 5½ feet radius. As afterward corrected by Muschenbroek, the length was 57,033 toises. In 1635 Norwood in England repeated the experiment, measuring along the road the distance between London and York, making the degree 367,176 feet, or 57,800 toises. Toward the close of the same century Picard first applied the telescope attached to a quadrant, and furnished with cross wires, to observe the angles for his triangulation, and twice measured between Amiens and Malvoisine with wooden perches a base of 5,663 toises, or nearly 7 m. in length, employing also at the other extremity a base of verification of 3,902 toises. The celestial arc of 1° 22′ 55″ was measured by a sector of 10 feet radius. He made the degree 57,060 toises, a result very nearly accurate, attained by a fortunate compensation of errors in his method and in his standard of measure. In 1718 the second Cassini published a work upon the magnitude and figure of the earth, with an account of measurements further north and south on Picard's line made by La Hire and himself. About the time of Picard's observations the question began to be agitated, whether the form of the earth was really that of a true sphere. The tendency of the centrifugal force of bodies revolving upon their axis, established by Huyghens and Newton, must evidently be to throw their movable particles from the poles toward the equator and there accumulate them in a belt, increasing the equatorial diameter. Newton calculated that to maintain the hydrostatic equilibrium the proportion of the polar to the equatorial diameter must be as 230 to 231. Richer, who was sent by the academy of sciences of Paris to Cayenne in 1672, observed that the pendulum which vibrated seconds in Paris lost about 2½ minutes daily at Cayenne. This fact, as Newton explained in his *Principia*, must be a consequence of the reduction of the force of gravity, either by effect of the centrifugal force or of increased distance from the centre. The deductions of Newton and Huyghens that the earth was a spheroid like that already observed of Jupiter, flattened at the poles, conflicting with the opposite conclusions of the first Cassini, induced the academy of sciences to cause exact measurements of meridional arcs to be made both near the equator and the polar circle. The celebrated commission of their members left Paris in 1735, Bouguer, La Condamine, and Godin to join in Peru the officers appointed by Spain, Antonio d'Ulloa and Jorge Juan; and Maupertuis with 4 others to proceed to the gulf of Bothnia, where they were joined by the Swedish astronomer Celsius. Ten years were spent by the party in Peru in the measurement of an arc of over 3° in length, extending from lat. 2′ 3″ N. to 3° 4′ 32″ S. In 2 measurements of the original base the difference was hardly 2½ inches; and a second base of 5,259 toises differed when measured less than a toise from its length as calculated from the triangles. The length of the degree at the equator, reduced to the level of the sea, was calculated by Bouguer at 56,753 toises, or 362,912 feet; by La Condamine, at 56,749 toises; and by Ulloa, at 56,768 toises. The northern party found a place for their operations between Tornea in Lapland and the mountain of Kittis, 57′ 29.6″ further north, in lat. 66° 48′ 22″. The difference of latitude being determined, they measured a base line upon the frozen rivers, 2 measurements giving a difference of only about 4 inches. The arc being then determined, it was found to give 57,422 toises to the degree. With this result they returned to France, being absent only 16 months. The greater length of the degrees as they approach the poles was thus established, and consequently the greater equatorial than polar diameter of the earth. Multiplied measurements in different parts of the earth now became important to determine its true figure. They have been made in various countries, and confirm the general conclusions of Huyghens and Newton. La Caille's measurement at the cape of Good Hope in 1751, the only one in the southern hemisphere, presented anomalies, or showed great irregularity in the figure of the earth, which were not explained till, nearly a century afterward, the arc was remeasured with great care under the auspices of the British government, and it was shown that the discrepancy was owing principally to the deviation of the plumb

line of La Caille by attraction of the mass of the mountain near by. In North America the first measurement of this character was by Mason and Dixon in 1764–'5, on the peninsula between Delaware and Chesapeake bays. The arc was measured throughout with wooden rods, and the degree in mean lat. 39° 12′ was found to be 363,771 feet, or 68.896 English miles. It has never been supposed that this was a very exact measurement, but its accuracy has not been disproved. In 1784 measurements were commenced larger than any ever before undertaken for the purpose of accurately determining the difference of longitude between the observatories at Paris and Greenwich. Instruments of great size and improved construction were prepared expressly for this work, and the base line of 27,404 feet upon Hounslow heath was measured once with wooden rods of 20 feet length, and once with glass rods of the same length in frames. The junction of the triangles on the two sides was completed in 1788; but the operations on the English side were regarded only as a portion of the full survey of the island to be afterward carried out. Still more extensive surveys were commenced in France in 1791, with the object of obtaining the exact length of the quadrant of the meridian, in order to make use of a definite part of this natural and permanent quantity as a standard for all linear measures. The pendulum vibrating seconds in some determined latitude had been proposed as a means of furnishing an unchangeable measure, but it was given up because of its dependence upon the element of time, the measure of which is arbitrary, and its sexagesimal divisions are inadmissible as the foundation of a system of decimal measures. Local causes also, as the geological structure of the locality, affect the rate of its vibrations. The length of the quadrant of the meridian, not being liable to these objections, was adopted instead, and a new measurement was carried out on the meridian of Paris under the distinguished astronomers Delambre and Mechain, and the work was not interrupted by the political disorganizations of the years 1792, 1793, and 1794. The line was extended across France from Dunkirk to Barcelona, making an arc of about 9°, and every precaution was taken to insure the most perfect accuracy in the measurements. The base line near Paris was more than 7 m. in length (6,075.9 toises), and another of verification of 6,006.25 toises near the southern extremity of the arc differed by measurement less than a foot in length from its extent calculated from the triangles extending from the first base more than 436 m. distant. Though this arc thus determined was sufficient for the purpose required, the French astronomers in 1805, after an interval of 3 years, began to carry the measurement still further south, Biot and Arago directing the work after the death of Mechain. The island of Ivica in the Mediterranean was connected with the system by a triangle, one side of which exceeded 100 m. in length; and by means of another the line was made to reach Formentara, distant 12° 22′ 13.39″ from Dunkirk, its northern extremity. The result of this extension affected the quadrantal arc before obtained so little, that the standard unit, the *mètre*, equal to the $\frac{1}{10,000,000}$ of the quadrant, would differ scarcely $\frac{1}{250,000}$ of the value before given it. A singular anomaly was noticed upon some portions of this arc, and the same was observed in the English surveys, that where these portions were considered separately, the length of the degrees appears to increase toward the equator. This is supposed to be owing to some disturbing cause, as, possibly, inequalities in the density of the strata which affected the instruments in use upon them. The effect is to produce a slight uncertainty in the exactness of the result obtained, and in the calculated proportion of the polar to the equatorial axis of the earth. The length of the quarter of the meridian was found to be 5,130,740 toises. Of the other measurements which have been made of an arc of the meridian, the most important are those conducted in Hindostan by Col. Everest, in continuation of the work commenced by Col. Lambton in the early part of the present century; and those by Struve and Tenner in Russia (the latter commenced in 1817 and completed in 1853). A small arc of 1° 35′ was measured near Madras by Col. Lambton; and another was commenced from Punnæ in the southern extremity of the peninsula, in lat. 8° 9′ 32.51″, and extended to Damargida, lat. 18° 3′ 15″. After Lambton's death in 1823, Col. Everest carried the work on further north for some time. In 1832, after an interruption, it was resumed and continued till 1840, when it reached Kaliana, lat. 29° 30′ 48″, thus including 21° 21′ (1,477 m.). Every precaution was taken, and the most perfect instruments were provided, to insure the utmost accuracy; and notwithstanding the natural obstacles of the climate, the heat, rains, and thick atmosphere, the malaria of the plains, and the impenetrability of the jungles, the results obtained from the bases of verification indicate as great exactness as has been attained in the best European measurements. The whole extent of the Russo-Scandinavian arc is from Ismaïl near the mouth of the Danube, in lat. 45° 20′, to Fugeloe in Finmark, lat. 70° 40′. The portion extending N. from Tornea (4° 49′) was measured by the Swedish and Norwegian engineers. The ground throughout the whole extent of the line is remarkably favorable for the execution of this work, on account of its freedom from great irregularities of surface; but in the southern part forests spreading over a level country have rendered it necessary to raise many temporary elevated stations; and in the north the extraordinary refractions of that region have added to the difficulties of the work. This arc, and that of Hindostan, give the measure of a large portion of the quadrant of the meridian, leaving only the degrees between 29° 30′ and 45° 20′ unmeasured from lat. 8° 9′ to 70° 40′.

The French arc, extending from lat. 38° 40′ to 51°, fills up a portion of this gap, and they all together afford abundant data for an exact computation of the curvature of the meridian; and this is rendered the more certain from the standards of length used in India and Russia having been directly compared. Other arcs have been measured by Bessel and Bayer in Prussia; Schumacher in Denmark; Gauss in Hanover; beside a few others of less import. The longest arc measured in the progress of the U. S. coast survey is one of 3½°, extending from Nantucket to Mount Blue in Maine. Great confidence is felt in the accuracy of this measurement, from the extreme care with which the triangulation is conducted. The work is not yet quite completed. An arc of parallel will also be measured along the Mexican gulf.—From the various measurements that have been already made, different values have been calculated for the ellipticity of the earth, or the proportions between the polar and equatorial diameters. Prof. Airy, before the completion of the recent surveys, found the ellipticity $\frac{1}{299}$, and Bessel afterward made it $\frac{1}{299}$. The French and Indian arcs give a smaller ellipticity, as $\frac{1}{316}$, but the Russian, it is thought, will be about $\frac{1}{300}$. The following statement presents the average of several of the measurements: Equatorial diameter, 41,843,330 feet, or 7,924.873 miles; polar diameter, 41,704,788 feet, or 7,898.634 miles; difference of diameters, or polar compression, 138,542 feet, or 26.239 miles; ratio of diameters, 302.026 : 301,026; ellipticity, $\frac{1}{301.026}$; length of degree at equator, 362,732 feet; length of degree at lat. 45°, 364,543.5 feet. Profs. Airy and Bessel, calculating from different sets of measurements, obtained the following results:

	Airy, miles.	Bessel.
Equatorial diameter.....	7,925.648	7,925.604
Polar diameter.....	7,899.170	7,899.114
Polar compression.....	26.478	26.471
Ratio of diameters.....	299.33 to 298.33	299.15 to 298.10

The ellipticity of the earth is always expressed by a larger fraction than the above when computed from observations upon the vibrations of the pendulum in different latitudes. It is variously given from $\frac{1}{289.3}$ to $\frac{1}{286.3}$. These observations have been made at so large a number of places, that the effects of local causes of irregularity would be expected to disappear; yet there is an unexplained discrepancy with the results of the geodetic method. This is perhaps owing in part to the variable resistance opposed by air of different densities, the effect of which can be obviated by conducting the experiments in a vacuum. The ellipticity has also been calculated from some irregularities in the motions of the moon, caused by the equatorial protuberance; and it may well be remarked as an extraordinary fact that from this source a strong confirmation should be afforded of the correctness of the results obtained from the measures of the meridional arcs. The ellipticity thus obtained is generally $\frac{1}{306}$ or $\frac{1}{304}$, different values being allowed for the rate of increase in the density of the earth from the surface toward the centre. Degrees of longitude might be measured instead of latitude for determining the figure of the earth; but the difficulty would be in the precise estimation of differences of longitude in the celestial arc. The close approach of the earth in its general form to the figure of hydrostatic equilibrium forcibly suggests the probability of the particles which compose its mass having been in condition to move freely together under the influence of the centrifugal force and their mutual attractions. The conditions that now obtain upon the outer portion of the earth in the mobility and transporting power of its waters, which cover ⅔ of its surface, may be regarded as sufficient to give, in long periods of time, the observed external form; but the indications afforded by the pendulum of regularly increasing gravity from the equator toward the poles, and hence of symmetrical arrangement of the layers throughout, imply the existence of similar conditions during the entire period of the construction of the earth.—The form and dimensions of the earth being obtained, calculations respecting its density or weight may be made by several distinct methods. The one first applied was originally suggested by Bouguer—a comparison of the attractive power of a mountain of known dimensions and density with that of the earth of known dimensions, whence its density might be computed. Newton had already estimated that a hemispherical mountain 3 m. high and with a base of 6 m. diameter would cause a plummet to be deflected 1′ 18″ from the vertical. In making the trial the plummet is attached to a delicate astronomical instrument, with which observations are made to determine the meridian altitudes of stars near the mountain, and on the same parallel at a distance accurately determined and sufficiently far off to be beyond its influence. The difference in the 2 altitudes shows the power of attraction. Observations are sometimes made from stations on opposite sides of the mountain, and the result is then obtained by a different plan from the above. Bouguer, in 1738, observed the influence of Chimborazo in deflecting the plummet, and unsuccessfully endeavored to compute its amount from observations made at 2 stations on the S. side only. In 1772 Dr. Maskelyne proposed to the royal society to try the experiment upon some mountain in Great Britain; and the society thereupon appointed a "committee of attraction," including in it, with Maskelyne, Cavendish, Franklin, and Horsley. Mr. Charles Mason was intrusted with the selection of a proper hill, and finally Schehallien in Perthshire, Scotland, was fixed upon. The primary measurements were made by Mason in 1774, to determine the distance apart of the stations to be used, one on the N. and the other on the S. side of the hill, under similar slopes. By triangulating, Dr. Maskelyne found this distance to be 4,364.4 feet, corresponding in that latitude to a

meridional arc of 42.94″. But by 337 observations the difference of latitude appeared to be 54.6″, giving 11.6″ as the double attraction. By complicated calculations, devised by Cavendish and carried out by Dr. Hutton, the density of the earth was computed to be to that of the hill as 17,804 : 9,933. Dr. Playfair, after carefully examining the geological structure of the hill, made the probable mean specific gravity of the earth to be between 4.56 and 4.87. By a similar experiment made by Col. James, superintendent of the ordnance survey, at Arthur's Seat, the mean density of the earth has been found to be 5.316.—A second method of estimating the density of the earth is by an experiment exceedingly delicate and beautiful, in which the attractive power of small spheres of known weight is weighed and compared with that of the earth. The principle of this method has also been recognized by Newton, in his observation that the attraction at the surface of any sphere is directly as its radius, but incomparably less than its tendency toward the earth, or in other words, its weight. The experiment was devised by the Rev. Mr. Michell, who also prepared the apparatus with which it was first conducted by Cavendish ("Philosophical Transactions," 1798). Two balls of lead of about 2 inches diameter were fixed one at each end of a slender wooden rod 6 feet long, which was suspended by a fine wire 40 inches long attached to the centre of the rod. At each extremity of a support of the length of the rod was placed a leaden sphere of 174 lbs. weight; and the support was adjusted upon a centre exactly beneath the centre of the rod suspended above it, so that the great balls could be swung around and present their opposite sides in turn to opposite sides of the smaller balls. When brought near to the latter as they swung at rest, protected by a glass case from currents of air, they turned toward the large balls, slightly twisting the wire till its torsion equalled the attractive force. This observation being made through a telescope at a little distance off to avoid disturbing influences, the large balls were then moved round, and a similar measure of the movement was made on the other side. Cavendish after a long series of trials found the attractive force equal to $\frac{1}{4\,3\,0\,0}$ of a grain weight, the centres of the balls being 8.85 inches apart, and he computed from this the density of the earth to be 5.48 times that of water. The experiment has been repeated by Reich of Freiberg and Baily of London, the latter making more than 2,000 observations. Reich made the density 5.44, and by a still later trial ("Philosophical Magazine," March, 1853), 5.58. Baily found it 5.66. It is remarkable that Newton should have stated in his *Principia* (iii. prop. 10) that the quantity of matter in the earth is probably 5 or 6 times what it would be if all were water. Another method of determining the density is by comparison of the different rates of vibration of the same pendulum at different distances from the centre; either at the summit and base of a mountain, or on the surface and at a considerable depth below it. The Italian astronomers Plana and Carlini, from their experiments on Mont Cenis, in Savoy, obtained the figures 4.950 as the result. Professor Airy made a similar experiment at the Harton coal pit, near South Shields, in 1854. He found that a pendulum vibrating seconds at the surface gained 2½ seconds per day at the depth of 1,200 feet; and he hence computed the density of the earth to be 6.565. Sir John Herschel ("Outlines of Astronomy," 5th ed., p. 559) thus presents the final result of the whole inquiry: "The densities concluded being arranged in the order of magnitude:

Schehallien experiment, by Maskelyne, calculated by Playfair	D = 4.713
Carlini, from pendulum on Mont Cenis (corrected by Giulio)	4.950
Col. James, from attraction of Arthur's Seat	5.316
Reich, repetition of Cavendish experiment	5.438
Cavendish, result 5.48, corrected by Mr. Baily's recomputation	5.448
Baily's repetition of Cavendish experiment	5.660
Airy, from pendulum in Harton coal pit	6.565
General mean	5.441
Mean of greatest and least	5.639

calculating on 5½ as a result sufficiently approximative and convenient for memory; taking the mean diameter of the earth, considered as a sphere, at 7,912.41 m., and the weight of a cubic foot of water at 62.3211 lbs.; we find for its solid content in cubic miles, 259,373 millions, and for its weight in tons of 2,240 lbs. avoird. each, 5,842 trillions ($=5842 \times 10^{18}$)." All these experiments give a less density to the earth than would appear to be required by the somewhat compressible nature of its materials, and to explain this the theory of the existence of a high degree of temperature in the interior is appealed to by some as presenting a sufficient counteracting influence. The probabilities of the existence of such conditions have been considered in the article Central Heat.—The various divisions of the earth's surface are described in the article Geography; its structure is treated in Geology. See also Physical Geography. The subject may be further studied in the following works: Steffens, *Beiträge zur innern Naturgeschichte der Erde* (Berlin, 1801); Ritter, *Die Erdkunde im Verhältnisse zur Natur und Geschichte des Menschen* (Berlin, 17 vols., 1832–'52; not yet complete), and other writings of the same author; Steinhuser, *Neue Berechnung der Dimensionen des Erdsphäroids* (Vienna, 1858); Burmeister, *Geschichte der Schöpfung* (Leipsic, 6th ed. 1856); Sandberger, *Der Erdkörper* (Hanover, 1856); Berghaus, *Was man von der Erde weiss* (Berlin, 1857, parts 19–23); Newton's *Principia;* Laplace, "System of the World," Harte's translation; Humboldt, "Cosmos" (5 vols., 1844–'58); Guyot, "Earth and Man" (revised edition, Boston, 1858); Sir John F. W. Herschel, "Outlines of Astronomy" (5th ed., 1858).

EARTH WORM (*lumbricus terrestris*, Linn.), an articulate animal belonging to the abranchi-

ate division of the class of annelids. (See Annelida, for the characters of the class.) This well-known worm has a long, cylindrical, contractile body, divided into many apparent rings (sometimes 150) by transverse wrinklings; the internal surface of the muscular envelope sends off annular septa, dividing the cavity of the body into as many chambers as there are segments, the partitions having openings which allow the passage of the contents of the general cavity from one chamber to the others. Each segment is provided with *setæ* or bristles, beginning at the 14th ring from the head, 4 on each side, united in pairs, forming 8 longitudinal rows, of which 4 are lateral and 4 inferior; they are short and rough, and are used as fulcra during creeping or climbing in the ground. The sense of touch is very acute, as is shown by the quickness with which they retire into the ground when touched, or at the jar produced by an approaching footstep; the sense is believed to be most acute toward the head, especially in the 1st segment. The eyes are wanting. The mouth is near the anterior extremity of the body, without teeth, with 2 somewhat prominent lips; the pharynx is simple, short, and muscular, the œsophagus narrow, the stomach very muscular, and the intestine short, straight, constricted by the muscular septa, and opening at the posterior extremity of the body. The blood is red, and the circulation is complete and closed; the several pairs of simple transverse canals, situated above the stomach, whose pulsations may be distinctly seen, may be considered the heart. The dorsal vessel lies upon the intestinal canal enveloped in the hepatic tissue. The blood, though red, is quite different from that of the vertebrates; according to Siebold, it contains colorless, spherical, unequal-sized granular globules; these, Quatrefages says, are not part of the blood, but belong to the fluid of the general cavity; the latter maintains that the coloring matter is in simple solution. There is no apparent external organ of respiration, and the peculiar canals in the abdominal cavity are regarded by some as internal branchiæ or aquiferous vessels. The structure of these organs is little understood; but in all genera of the division there are at the commencement of the intestine very tortuous canals, opening generally on the ventral surface; these canals are lined with ciliæ, which have an undulatory movement always in one direction; they never contain air, according to Siebold, but circulate an aqueous respiratory fluid by means of the ciliæ; even the terrestrial earth worms can live only in damp earth, from which they obtain the necessary aqueous fluid. In the *lumbricus* these canals are surrounded by a distinct vascular net-work; they appear to end in loops, and their external orifices have not been satisfactorily ascertained. The most probable opinion is that the respiration is carried on principally by the general integument, and partly by the vascular system on the walls of the intestine; the ciliated canals described by Siebold are believed by Quatrefages to be organs for the secretion of the mucus which invests the body; but Dr. Williams (in his "Report on the British Annelida" to the British association, in 1851) considers them as utero-ovaria. The *lumbrici* reproduce by sexual organs; their eggs are spherical and present nothing remarkable; both sexes are united in the same individual. During the breeding season, from 6 to 9 of the segments (from the 26th to the 37th, as generally described) are developed into a kind of collar, nearly surrounding the body, by which these animals seize each other during coition; its component glandular follicles secrete a whitish viscid fluid, probably used for the formation of their cocoons or egg-cases. According to Dufour, these cocoons have a long narrow neck, each, in the large species, containing from 1 to 6 eggs; the statement of Montègre that the young are born alive seems to be confirmed by the observations of Dr. Williams (*op. cit.*), who says that they escape from the egg before leaving the body of the parent; these conflicting opinions have been reconciled by some authors by calling these animals ovo-viviparous, producing their young sometimes completely formed, and at others surrounded by their egg-like envelope; it is probable that, like the leech, most *lumbrici* lay oviferous capsules, fringed at the ends, in which the young are developed without undergoing metamorphosis. It seems certain from the experiments of Dufour (*Annales des sciences naturelles*, t. v. p. 17, and t. xiv. p. 216, 1st series) that the earth worm reproduces by means of eggs; he describes them as an inch in length, of a corneo-membranous consistence, deposited in the earth at a depth of from 6 inches to 6 feet, in localities where the soil is neither inundated nor too dry, isolated, and each egg containing 1 or 2 young. In this case the eggs cannot properly be called cocoons, as the young undergo no metamorphosis in them; this would be the mode of reproduction usually noticed in the class; in the branchiate annelids it is stated by good observers that some are born alive and mature, and others of the same species are developed from eggs deposited in a gelatinous covering; so that there is no anomaly in the mode of reproduction described by Dr. Williams, and there would seem no necessity for maintaining that the viviparous mode of reproduction rested on mistaken observations, or that the excluded worms in these cases are entozoa, which, it is well known, are very common in the earth worm. Still, the subject is much in need of a thorough revision. Earth worms live in moist earth, in which they make galleries in all directions, swallowing the earth as they proceed; their food is principally soft and decaying vegetables, as may be proved by any one who chooses to watch a garden walk by the light of a lantern on a damp evening, when they may be seen creeping out of their holes, elongating their first tactile segment, feeling in all directions for food, and, seizing any suitable substance with their projected proboscis, retiring backward into the ground; their constant presence wherever there is decaying vegetable matter proves that their food is principally

derived from such substances; they also, as Montègre observed, will feed upon animal matters; it seems more reasonable to believe, with De Blainville, that they swallow earth for the purpose of making progress in their galleries, than that they do this to extract humus or any other nutritious substance from it. They seek each other chiefly at night and in the latter part of spring, though some species have been noticed together at all times of the day, and during all the warm months; it is well known that they are most abundant on the surface of the ground during and after nocturnal rains. It has long been believed that this animal possesses a remarkable power of reproducing parts lost by accident or design, even to the extent of forming perfect individuals from separated portions; the experiments of Dugès prove that very important parts may be reproduced, and it may easily be believed that in a worm divided into two, the anterior portion might produce an anus by the simple contraction of the wound; but that the posterior portion should be able to reproduce cerebral ganglia, mouth, stomach, cardiac and sexual organs, cannot be admitted; the anterior may survive a long time, but the posterior division gradually dries up and dies. Dr. Williams, after attending to the experiments of Bonnet, Spallanzani, and others, to which Prof. Owen gives assent, says: "On the authority of hundreds of observations, laboriously repeated at every season of the year, the author of this report can declare with deliberate firmness, that there is not one word of truth in the above statement." In 1853 Mr. Newport exhibited before the Linnæan society of London 3 specimens of earth worms, one of which was living, in which more than ⅓ of the anterior part of the body had been restored, smaller in diameter and with shorter segments than the anterior portion; and he says that it is not uncommon to find specimens with parts similarly restored. Though generally a despised creature, and occasionally marring the beauty of the garden walks by little hillocks of earth, they not only do not injure vegetation, but are really useful in permitting air and water to penetrate the ground through the channels which they pierce in every direction, manuring the fields, and throwing up fine dirt around the roots of grass; a field in which no worms exist can be safely put down as of little value to the agriculturist; they are most active in spring, when most needed, and retire during winter deep into the ground; according to Mr. Darwin, they perform under ground that which the plough and the spade do on the surface, and have covered a field manured with marl, in the course of 80 years, with a bed of earth 13 inches thick. Worms also furnish food for birds, moles, frogs, and other small animals, and are used as bait for many kinds of fish. The rapid ascent and descent of worms in the ground are easily understood from the action of their numerous setæ; they have often been seen high up on perpendicular surfaces, and in situations which they could not have reached without climbing perpendicularly. In their movements they display great muscular force, each seta being moved by its appropriate system of muscles; Dr. Williams says that these setæ, with their fine hair-like appendages, will actually penetrate a deal board, and that the path of a worm on such a polished surface will show under the microscope 4 series of minute perforations. This would hardly explain their ascending perpendicular surfaces, especially when of glass or similar impenetrable material; in such cases, which are incontestable, they must retain their hold by means of the tenacious mucus with which their skin is covered. There is no question that many species have been confounded under *L. terrestris* (Linn.). The largest European species is called *L. gigas*, and is 18 inches long, and as large as the little finger; other common and smaller species are *L. anatomicus* and *L. trapezoides*. Whether all the American species are distinct or not has not been sufficiently demonstrated; there are certainly some species described peculiar to this country, but probably the *L. terrestris* is common to both hemispheres. The history and habits of this commonest of animals, trodden under foot by everybody, show how creatures apparently the best known may give rise to the most contradictory opinions among naturalists, and how a complete study of the most insignificant worm may illustrate some of the highest problems of animal physiology.—Those who wish to pursue this subject into its details are referred to the writings of Dufour, Dugès, Milne-Edwards, Blanchard, and especially Quatrefages in the *Annales des sciences naturelles* since 1828; to the article "Annelids," in the "Cyclopædia of Anatomy and Physiology;" to the report of Dr. Williams, above quoted; and to Siebold's "Comparative Anatomy," with its ample references to the best works.

EARTHENWARE. See Pottery.

EARTHQUAKE. In every part of the world the surface is subject to be shaken at times by movements taking place in the interior and transmitted somewhat like a wave to distant regions. No country escapes these visitations, but in volcanic districts they occur more frequently than elsewhere; and commencing in these, they have been known to pass beneath sea and land, from one hemisphere to another, till full ⅛ of the entire surface of the globe has been more or less disturbed by the movement. Such was the great earthquake of the year 1755, known as that of Lisbon, which will be described below. Some countries are so subject to these disturbances that the habitations of the people are built low, with broad bases and substantial walls, with particular reference to their stability against the shocks. This is the case throughout Central America, and in Chili, Peru, &c. Taking into account the whole surface of the earth, there is probably not a day that passes without the occurrence somewhere of a sensible disturbance of this kind, and hardly a month

without one or more worthy of note. The same countries have continued to be frequently visited by earthquakes from remote periods. Calabria, the southern extremity of Italy, has been repeatedly devastated since its early settlement by the Greek colonists, and, together with the neighboring island of Sicily, has been the scene of some of the most terrible earthquakes on record. From Feb. 1783, to the end of the year 1786, a period of nearly 4 years, this country was almost constantly disturbed. No fewer than 949 shocks were experienced in the first of these years, of which 501 were shocks of the first degree of force. Lyell observes that these convulsions were not remarkable above many others for their duration, violence, or extent, but great importance is given to them from the minuteness of the observations of men competent to collect and describe with accuracy the physical facts which throw light on geological questions. The details that have been recorded of the earthquakes in the countries bordering on the Mediterranean would make this region appear more subject to them than any other part of the globe; but had any other volcanic region been settled during the same periods by a population of the same degree of civilization, it is probable that the records of the two would not have materially differed in this respect. Among the earliest accounts of earthquakes of particular interest is that which resulted in the destruction of Herculaneum and Pompeii in the year 63, which was 16 years previous to the time when those cities were buried in the ashes from Vesuvius. The ancient city of Antioch in Syria was almost destroyed in the year 115, at the time of the visit of the emperor Trajan, who was himself hurt. In 458 it was again visited by an earthquake, and in 526 occurred the most disastrous one of which any record has been preserved. Gibbon states that 250,000 persons are said to have perished at this time, a conflux of strangers to the festival of the Ascension swelling the multitudes belonging to the city. "History," he remarks, "will distinguish the periods in which these calamitous events have been rare or frequent, and will observe that this fever of the earth raged with uncommon violence during the reign of Justinian. Each year is marked by the repetition of earthquakes of such duration that Constantinople has been shaken above 40 days; of such extent that the shock has been communicated to the whole surface of the globe, or at least of the Roman empire."—The approach of earthquakes is heralded by several premonitory symptoms of an unmistakable character. The air appears to be affected in some respect, perhaps in its electric condition, and the brute animals show a sensitiveness to this by uttering cries of distress and running wildly about. Men sometimes are affected with dizziness, and a sensation like seasickness. The atmosphere is often hazy for months, and the sun seen through it appears red and fiery. The weather suddenly changes from fierce gusts of wind to dead calms, and rains pour down in torrents at times, or in places in which they are usually of rare occurrence. Immediately before the shocks occur, the air is generally very still, while the surface of the ocean or lakes is unusually disturbed. A sound then breaks upon the stillness like distant thunder, or like a carriage rumbling afar off upon a rough pavement; or it may break at once with an awful explosion, as when the peal and the flash come together from every part of the cloud in which one is enveloped; at the same time the ground is shaken and lifted upward, or thrown forward, as by the passage of an irresistible wave beneath it. The shocks may be repeated several times in quick succession, or recur after long intervals; the movements may be so great as to rend the surface into chasms, and these may open and shut again, or remain in fissures of the width of a few feet or yards, and extending to unknown depths; smoke and flames are occasionally sent forth from them during the continuance of the earthquake, even if the region be not volcanic. Torrents of water are ejected from these chasms, and springs of water are often forced by the convulsion into new outlets and directions. Objects upon the surface, as dwellings, trees, and animals, are engulfed in the chasms; and by subsidence of the surface, large trees, mountains even, and whole cities are swallowed up. Occurring as they most frequently do along the seaboard, the water is observed commonly to retire to some distance, leaving the harbors dry, and then to return in a great wave of many feet in height, which sweeps every thing before it. This may occur by the progress of the great wave, the recession being occasioned in the same way as the similar movement upon a small scale noticed along the shore as a steamboat approaches it, the water first receding, and then returning in a great wave; or it may be owing to a tract being uplifted in the sea at some distance, toward which the waters would first be drawn from every direction, and immediately after be propelled back with redoubled force.—Of all the calamities to which man is exposed, there are none of so fearful a character as earthquakes; none involve such terrible and devastating destruction to life and property. There are none of the approach of which he is less forewarned, and none against which he can take fewer precautions. The very mysteriousness of the danger oppresses him with terror. He is ignorant in what form it is most imminent, or in what direction to seek a way of escape. Of modern earthquakes, that of Lisbon, in 1755, and that of New Madrid, Mo., in 1811, present some of the most interesting details. That of Chili, in 1822, is interesting for the permanent elevation of the country between the Andes and the coast which attended it. The area thus raised has been estimated to equal fully 100,000 square miles, and the height of the elevation to vary from 2 to 7 feet. Lines of sea beaches at higher levels and further inland indicate the previous lifting up of the same region at different times along the same lines.

A depression of the land was occasioned in the island of Jamaica in 1692, when Port Royal, the capital, was carried down, with the greater part of the buildings in the city, beneath the surface of the water. A thousand acres or more thus sank in less than one minute, the sea rolling in and driving the vessels in the harbor over the tops of the houses. A similar catastrophe occurred on a much more gigantic scale in the island of Java in 1772, when Papandayang, then one of the loftiest of the volcanoes of this region, was in action; an area suddenly sank down, including the mountain of 15 m. long and 6 m. broad, carrying with it 40 villages, and destroying 2,957 of the inhabitants. The great earthquake of Lisbon commenced on Nov. 1, 1755. The rumbling sound below the surface was immediately followed by the shock, which threw down the principal portion of the city. In the short space of 6 minutes it is believed that 60,000 persons perished. The sea retired, leaving the bar dry, and returned in a great wave 50 feet or more in height. The mountains around were shaken with great violence, and were even rent and thrown in fragments into the valleys below. Multitudes of people sought safety from the falling buildings by crowding upon the marble quay, which had just been constructed at great expense. It suddenly sank with them like a ship foundering at sea; but when the waters closed over the place no fragments of the wreck, none of the boats and vessels near by that were drawn into the whirlpool, and not one of the thousands of bodies carried down, reappeared upon the surface. Over the spot the water stood 600 feet deep; and beneath this, locked in the fissured rocks, in chasms of unknown depth, lie the relics of what was the life and wealth of this portion of the earth's surface in the middle of the 18th century. These rocks are the clayey and other comparatively soft strata of the tertiary formation. When in some future epoch they are raised again to the surface by a convulsion of the same nature with that which engulfed them, the vestiges they contain may reappear, converted in part or wholly into stone, like fossils entombed when the strata were deposited. The portion of the surface of the earth that was shaken by this earthquake was estimated by Humboldt as equal to 4 times the extent of Europe. The shock was felt in the Alps and on the coast of Sweden. In Germany the thermal springs of Töplitz disappeared for a time, and again burst forth, deluging the region around with ochre-stained waters. The waters of the lakes in Scotland, as Loch Lomond especially, rose suddenly more than 2 feet, and then subsided below their usual level. On the shores of Barbados, Martinique, and Antigua, the tide suddenly rose 20 feet, and the sea was of inky blackness. Even the distant waters of Lake Ontario were strangely agitated, and the shock was sensibly felt along the coast of Massachusetts. In Deane's "History of Scituate" it is stated that the earth was seen to wave like the swellings of the sea, and occasionally break into fissures. This lasted for 15 minutes, during which chimneys were shaken down and houses disjointed. The sea roared with the unusual commotion, and with the rumbling of the earth the noise was more appalling than that of the loudest thunder. Water spouts burst forth, and springs opened, which continue to flow to this day. As the movement passed beneath the ocean, it was felt by several ships, the impression being like that produced by striking upon rocks. The motion is described as undulatory, and proceeding at the rate of about 20 m. a minute.—The earthquake of New Madrid, below St. Louis, on the Mississippi, in 1811, is the most important that has occurred in this country of which we have any record. Humboldt remarks that it presents one of the few examples of the incessant quaking of the ground for several successive months, far from any volcano. Over an extent of country 300 m. in length, from the mouth of the Ohio to that of the St. Francis, the ground rose and sank in great undulations, and lakes were formed, and were again drained. The surface burst open in fissures, from which mud and water were thrown as high as the tops of the trees. The direction of these fissures was generally from the N. E. toward the S. W., and the inhabitants, noticing this, felled the tallest trees at right angles to this line, and stationing themselves upon them, thus escaped being engulfed. Flint, the geographer, observed hundreds of these chasms 7 years after this catastrophe; and Lyell, who visited the same region in 1846, noticed many, which then appeared like artificial trenches, which might be traced for more than half a mile. They were generally parallel, and varied, according to his measurements, from 10° to 45° W. of N. The country is still called the "sunk country," and its extent, along the White Water and its tributaries, is 70 to 80 m. N. and S., and 30 m. E. and W. During the continuance of these convulsions the inhabitants distinguished 2 classes of earthquakes, those in which the movement was vertical, and those in which it was horizontal; the latter were regarded as far more desolating than the former. They continued until the destruction of the city of Caracas, which took place March 26, 1812. One evening, about this time, is described by the inhabitants of New Madrid as brilliant and cloudless, during which the western sky was a continued glare of vivid flashes of lightning, and peals of thunder were incessantly heard, proceeding apparently, as did the flashes, from below the horizon. In the destruction of Caracas, the whole city, with its splendid churches, was in an instant a heap of ruins, under which about 12,000 of its inhabitants were buried.—Fissures are occasionally met with in different parts of the country which extend through the solid rock to a great depth, and which were without doubt produced by earthquakes of some unknown period. A remarkable chasm of this nature may be followed

from the western base of the Shawangunk mountain at Ellenville, in Ulster co., N. Y., for about a mile to the summit. At the foot one may easily step across the fissure, but higher up it becomes wider till the hard vertical walls of sandstone are separated by a gorge several feet wide and of great depth. At the top the strata which sloped nearly with the mountain have curved over and assumed a horizontal position. An area of a hundred acres or more is here rent in every direction; the continuity of the surface is interrupted by sudden steps of rock, presenting abrupt walls, while the gorge traced up the mountain has spread out into a frightful abyss, more than a hundred feet wide. Among the loose rocks which lie upon the bottom, trees are seen growing, the tops of which hardly reach half way to the edge of the precipice.—Earthquakes of especial interest, from their late occurrence and destructive effects, are those of 1857 and 1858 of the kingdom of Naples, and of Mexico. The former commenced Dec. 16, 1857, and continued at intervals through the early part of January. In the city of Naples repeated shocks were felt, alarming the inhabitants, who often rushed from their houses into the streets, many fleeing from the city altogether. But as in former catastrophes of this nature, which laid waste the surrounding country, the city itself, though more or less injured, was singularly protected. This is supposed to be owing to the proximity of Vesuvius, which continued in eruption, discharging clouds of smoke, accompanied with terrific explosions. Resina at different times was in a continual state of vibration for hours together, the shocks appearing to proceed from the mountain. But the chief scene of destruction was in the provinces, particularly those of Principato Superiore and Basilicata. Potenza, the capital of the latter, was left without a single house inhabitable. Tito, Marsico Nuovo, Laurenzana, Porienza, Pollo, and other places, were reduced to heaps of ruins. The loss of lives was estimated by thousands; according to some statements made at the time, from 22,000 to 40,000. The late earthquake in Mexico occurred June 19, 1858. It extended throughout the valley of Mexico, demolishing many houses in the city, and also the aqueduct which supplies the city with water, and destroying property to the value of several millions of dollars. It was felt with more or less destructive effects in Guadalajara, Jalapa, San Luis Potosi, Toluca, &c. In the city of Morelis, the shock was the greatest ever experienced there, lasting 1½ minutes; and in Patzacuaro, 15 leagues further west, it was still more severe, levelling 4 churches, and many private houses. The city of Quito in Ecuador was almost entirely destroyed by an earthquake, March 22, 1859, and many thousand lives are said to have been lost. Several small towns north of the capital were destroyed at the same time.—The cause which produces the earthquake shock, and the manner in which it is communicated over vast distances in short time, have been variously explained. Slight impulses sometimes produce perceptible movements in what appears to be solid and fixed. Thus at Greenwich observatory the shutting of the outer gate has so jarred the transit telescope as to throw the star to which it pointed out of the field of view. The effect of the jarring of dams by the fall of water is also felt miles off. Various agents are well known to be at work in the interior of the earth, producing chemical changes, which are often attended with violent movements. By such forces immense columns of lava are lifted up in the craters of volcanoes, and stones of vast size are ejected. One mass of rock thrown from Cotopaxi, a distance of 8 or 9 m., was estimated to contain about 100 cubic yards of matter, consequently weighing over 200 tons. It has been suggested that many of the gases which are evolved from volcanoes may, under the immense pressure to which they are subjected in the interior, exist in a liquid or solid form, and that by a considerable increase of heat these are made to assume the gaseous form, and in doing this display an elastic power which no superincumbent mass can resist. It has been found that when powder is exploded in rocks a shock is communicated to distances varying with the quantity fired and the quality of the rock as to elasticity; and the rate of progress of this impulse has been observed to be from about 1,000 to 1,700 feet per second. Many instances have been recorded of the velocity of the earthquake shock, ascertained by noting the time at which chronometers at different localities have been stopped by it, and this has been found to vary from 1,000 to 5,000 feet per second. The movement in both these cases is no doubt of analogous character, though accompanied in the earthquake by a vastly increased display of force. Mr. R. Mallet, who has recounted these and other observations in his valuable essay on the dynamics of earthquakes, defines their efficient cause to be "a wave of elastic compression, produced either by the sudden flexure and constraint of the elastic materials forming a portion of the earth's crust, or by the sudden relief of this constraint by withdrawal of the force, or by their giving way and becoming fractured." When, as frequently is the case, the shock originates beneath the ocean, its effect is transmitted first in the wave of sound, which, rushing forward through the rocky crust of the earth at the rate of 8,000 to 10,000 feet per second, gives notice by its rumbling of the vibrating motion that is following behind. The great sea wave generated by the same movement, advances still more slowly than the vibration transmitted through the rocky strata, but at last pours in upon the land, its effects modified by the contour of the coasts and the depth of the waters through which it has passed. Lastly may come the atmospheric agitation and the sound of the outbreak, transmitted through the air. The vibrating movement imparted to the solid strata is the chief agency in the disastrous effects of earthquakes. Its rate of progress must vary with the varying elasticity

of the rocks, and a greatly increased shock must consequently be experienced in the passage of the wave from soft alluvial strata into the hard crystalline rocks, or *vice versa*. It was on this line of junction of the 2 formations that the most disastrous effects were experienced in the great earthquake in Calabria in 1783. It is by such an elastic wave, moving forward and suddenly back again, that Mr. Mallet explains the curious effects which have been observed in the twisting movement given to the blocks which form portions of columns, as if the upper stones had been partially turned around on the lower. Such effects were noticed by Darwin in the cathedral at Concepcion, and others of the same nature are described as having occurred to 2 obelisks in a convent in Calabria. The effect has also been referred to a vorticose or whirling motion, and by others to a rotary movement caused by the crossing of 2 waves of horizontal vibration. The Profs. Rogers "attribute the movement to an actual pulsation engendered in the molten matter itself by a linear disruption under enormous tension, giving vent explosively to elastic vapors, escaping either to the surface or into cavernous spaces beneath." By others the movement had previously been ascribed to elastic vapors, passing between the strata or between the crust and the fluid lava beneath it.—For further details the reader is referred to the work of Robert Mallet, C.E., and John W. Mallet, professor of chemistry in the university of Alabama, published in an octavo volume in 1858. It contains the able papers published from 1852 to 1858 in the "Transactions" of the British association for the advancement of science; that of 1858 reviewing the facts and theories of earthquakes, and illustrated by several fine maps. Mr. Mallet has also collected some interesting data respecting the distribution of earthquakes, having compiled a catalogue embracing nearly 6,000. In Guinea and southern Africa no earthquakes are recorded. The same may probably be said of Greenland. One spot in the Atlantic ocean, near the equator and about midway between Guinea and Brazil, appears to be peculiarly subject to them. Vessels passing over this tract almost always experience shocks, and the soundings are found to be subject to sudden and extreme variations, a depth of 400 fathoms being often directly succeeded by one beyond the reach of the sounding line. It is naturally inferred that this may be a submarine volcanic region.

EARTHS, in chemistry, a class of certain compounds of metallic bases and oxygen, which before the decomposition of some of them by Sir Humphry Davy were regarded as elementary bodies. The earths proper are alumina, glucina, zirconia, thoria, didymia, lantana, ceria, yttria, terbia, erbia. Silica, formerly regarded as an earth, is a combination of silicon with oxygen, and possesses the properties of an acid. The following possess alkaline properties, and are classed as alkaline earths: baryta, strontia, lime, magnesia, lithia. Excepting alumina, the pure earths are rarely seen; they are insoluble in water, and when taken up by acid solvents are precipitated white by ammonia or soda.

EARWIG, an orthopterous insect, of the family *cursoria* or runners, which also includes the cockroach; it belongs to the genus *forficula* (Linn.). All the 6 feet are formed for running; the wings are 4, the upper pair very short, coriaceous like the elytra of *colcoptera*, without veins, enclosing the under wings, which are folded both longitudinally and transversely; the mouth is formed for mastication; the body is long and somewhat flattened, and armed at the hinder end with a pair of curved blades shutting like scissors or nippers; there are 3 joints to the tarsus; the antennæ are filiform. These insects undergo a partial metamorphosis. They seem to form the connecting link between *coleoptera* and *orthoptera*, resembling the former in their elytra, and the latter in the shape of the wings and mouth, and the metamorphosis; for these reasons most English entomologists adopt for them the order *dermaptera* of Mr Kirby and Dr. Leach, considering them *coleoptera* with the metamorphosis and caudal appendages of *orthoptera*. They are common in moist earth, under stones, in decayed wood, and in similar damp and dark places; they are considered in Europe injurious to peaches, pears, apples, to greenhouse plants, and to pinks, dahlias, and other favorites of the flower garden. The full-grown insect, including its caudal forceps, is not quite an inch long, and its width is $\frac{1}{5}$ of an inch; the color is light brown. Being nocturnal insects, they creep in the daytime into any crevice or hole which can conceal them, and this has given rise to the popular belief that they enter the human ear; they might attempt this, but the waxy bitter secretion of the ear would probably prevent their entrance; there are no well authenticated instances of their doing this, and no harm could result if they did, as the drum of the ear would arrest them, and a drop or two of oil would soon destroy them by stopping up their respiratory tracheæ. The common way of catching them in England is by hanging up any convenient vessel or tube for them to crawl into in the morning, from which they are shaken and killed. In the larvæ there are no wings nor elytra, but the skin is changed several times; the nymph differs little from the perfect insect; in both these conditions they are voracious, even devouring each other. In this country there are several species, rather uncommon, and never injurious to vegetation.—The many-footed creeping animal erroneously called earwig in America (genus *iulus*), is not an insect, but a myriapodous crustacean, equally innocent of entering the human ear.

EASDALE, or EISDALE, an island of the Hebrides group, about $1\frac{1}{2}$ m. long, and of nearly the same width, and noted for its slate quarries, which have been worked 150 years. The island consists entirely of slate stone, and has been so much cut away that a large part of it is now even with or below the level of the sea.

EAST (Anglo-Saxon, *East;* the corresponding

word in many other languages having a similar etymological significance), the quarter in which the heavenly bodies rise. Due east is the direction toward the east, precisely at right angles to a horizontal meridian line; the reverse direction is due west. An object is said to bear due east when it is seen exactly in this direction; but it is said to be due east when it is on the same parallel of latitude as the observer, *i. e.*, when it may be connected with the observer by a line every point of which runs due east and west. An object that is due east will in N. latitudes bear N. of E., unless it be very near the observer, or he be very near the equator, for in other cases the parallel of latitude curves to the north, keeping at the same distance from the N. pole. A column of smoke, for example, over New York city, could it be seen at Nauvoo, would bear 5¾° N. of E., and smoke rising from Nauvoo would bear from New York 5¾° N. of W. The bearing is the direction in which a great circle from the observer through the object starts from the observer; while the course or actual direction is the direction of a line to the object cutting every meridian at the same angle. Madagascar is in a S. E. direction from New York, but bears due east. "Bearing" is sometimes used in the sense of course or actual direction instead of in the sense here given. East is a different direction for every spot on the earth's surface; at the poles there is no east or west; nor among the stars, except by reference to the nearest part of the earth's surface.

EAST FELICIANA, a N. E. parish of Louisiana, bordering on the Mississippi and Amite rivers; area, about 480 sq. m.; pop. in 1855, 14,101, of whom 10,266 were slaves. It has a moderately uneven surface, and the soil is well watered, fertile, and easily tilled. There are forests of pine, oak, and bay, and extensive plantations of sugar and cotton. In 1855 the productions were 16,970 bales of cotton, 2,464 hogsheads of sugar, 448,475 bushels of Indian corn, and 3,857 barrels of molasses. Value of real estate, $2,079,735. The parish contains a lunatic asylum and a college. Capital, Clinton.

EAST INDIA COMPANIES. The establishment of direct trade with the Indies was the aim of all the most enterprising cities and governments of early Europe. The Italian republics were long foremost in the trade, but they never entirely overcame the obstacles in the way of secure overland passage; and when the Turks were established in Europe and Africa by the conquest of Constantinople and Egypt, India became almost a closed land to the merchants of western Europe. Thus arose the necessity for a new channel of communication, less liable to interruption. Prince John of Portugal was foremost among the rulers who encouraged the then growing spirit of maritime exploration. A new way to the Indies was the dream of the day, under which Columbus discovered America, while Vasco da Gama first rounded the cape of Good Hope in 1497 and reached the Malabar coast in 1498. While the Spaniards colonized the new world, the Portuguese established themselves in India, and for nearly a century, with the help of the papal bulls in their favor, monopolized the trade, supplying all Europe with spices, silks, and Indian produce, and raising their country to the pinnacle of its wealth and power. When in 1580 Philip II. united Portugal to Spain, and presently began his war upon England, he closed the ports of his empire against British vessels. This was the first blow at the supremacy of Portuguese commerce in the East. The British were forced to get their supplies of Indian produce from the Dutch, who immediately raised the price of pepper by 200 per cent. The revolt of the Netherlands, and consequent exclusion of Dutch vessels also from Lisbon, till then the great European depot for Indian wares, at once compelled the Dutch to seek a direct passage to India. The English were not slow to follow their example, and thus during the last 10 years of the 16th century was laid the foundation in Holland and England for the great commercial corporations known to history as East India companies. After the union of Spain and Portugal, the Portuguese East India commerce, founded in 1498 and conducted on government account, was managed with laxity; all kinds of corruption grew up among officers and servants, and it was presently found that the trade was a losing business for the government. Hereupon the exclusive privilege of commerce with India was in 1587 granted to a company of Portuguese merchants, in consideration of the annual payment of a stated sum. Attempting to enforce its rights in India, the agents of this company found themselves in collision with the Portuguese government there, which was engaged in smuggling; they found the Portuguese hated by the natives, and their designs thwarted wherever possible by the Arabs. On the breaking out of the war between England, Holland, and Spain, which struck a disastrous blow at the India trade, the Portuguese company became unable to pay its annual tribute; and thenceforth it gradually declined, until in 1640 the company was finally abolished. Since that time the unimportant commerce of Portugal with India has been carried on by the crown; though an unsuccessful attempt was made in 1731 to establish another company.—The Dutch, driven from the southern passage, monopolized by the Portuguese, made three unsuccessful attempts at the opening of a way by the ocean which bounds Europe on the north. A north-east passage was never discovered, and the wars turned southward the attention of the Dutch. A "Company for Remote Parts" was formed at Amsterdam, and on April 2, 1595, 8 years after the establishment of the new Portuguese company, 4 small vessels, equipped with a capital of 70,000 guilders, sailed from the Texel under the command of Cornelius Houtmann, bound around the cape of Good Hope. Houtmann had been a prisoner, whether among the Turks or the Portuguese is uncertain, and was acquainted with the Portuguese East India trade. Several other companies, start-

ed in others of the United Provinces, finally joined that of Amsterdam, and in March, 1602, they received a charter from the states-general conferring on them the exclusive privilege of trade to the East Indies for 21 years, with the necessary civil and military powers. They began with a capital of 6,500,000 guilders; 6 towns were interested; 65 directors, chosen in stated numbers from each, equipped the vessels; 15 others had the general direction of affairs. They were so successful that in 20 years they divided among the stockholders the large sum of 30,000,000 guilders, more than 4 times the amount of the capital, beside owning vast amounts of property in colonies, fortifications, and vessels. The charter was extended to 1644; Batavia was founded; the commerce with Japan, which returned silver and copper for commodities, was extended; in 1641 Malacca, capital of the then neglected Portuguese East India possessions, fell into the hands of the Dutch by the treachery of the governor; and from 34 to 41 freighted vessels were sent out annually, of which from 25 to 34 returned loaded. Yet so rapidly did the English and French commerce increase during these years, that in 1644 the Dutch East India company could scarce command the 1,600,000 guilders required as a subsidy to the government, on again renewing its charter for 21 years. The peace of Westphalia, which secured the independence of the republic of the United Provinces, once more gave the company life. Between 1650 and 1670 they colonized the cape of Good Hope, at an expense of 20,000,000 guilders. In 1658 they succeeded in wresting Ceylon from the Portuguese; and the island of Formosa, which they then held, received a valuable colony of 30,000 expatriated Chinese, who brought industry and wealth with them. In 1661 they lost Formosa—Koxinga, a Chinese adventurer, expelling them from it. In 1663 they took possession of the most valuable Portuguese settlements on the Malabar coast. In 1666, after a prolonged struggle, they gained Macassar, and with it the monopoly of the spice trade. In 1665 the charter was with much opposition renewed till 1700, on condition of the payment of a large sum. At this time the civil and military expenses of the company, exclusive of those of the Macassar war, amounted to 3,500,000 guilders. Their report showed a prodigious extension of commerce and of territory. They held the principal seats of commerce in Ceylon, Sumatra, Java, Borneo, and in fact throughout the Indian archipelago. They commanded the trade with Pegu, Siam, Tonquin, Japan, the Banda and Molucca isles, Amboyna, &c. Batavia was then in all its glory, and the straits of Sunda on which it is situated had become, instead of those of Malacca, the channel to the further Indies. The charter was renewed in 1701, in 1741, and in 1776, the last time for 30 years, and on condition of paying down 2,000,000 guilders, with 360,000 annually. Turning their hands against every one in the East, and seeking by oppression of natives, exclusion of Europeans, and the forced production of some spices with prohibition of the cultivation of others, to rule the markets of the world and to extend and consolidate their dominion and wealth, the company was yet so exhausted by war with England and political expenses, that in 1781 the states-general were obliged to assist it with a loan. In the first French revolution it lost nearly all its possessions. The establishment of the Batavian republic, Sept. 15, 1795, terminated its existence, and the affairs of the company passed into the hands of the government. A new company was established in 1824, called the *Handel Maatschapij* or trading association. This company is the agent for the sale of the government produce in Europe, the carrier of this produce, and farms some branches of the public revenue of Java and the other Dutch East India colonies. In 1851 this company sent to Europe about $20,000,000 worth of produce, while the amount sent from the same colonies by private merchants was only about $10,000,000. The Dutch are still noted throughout the East for their narrow policy, and their extreme severity toward the natives whom they have reduced to their yoke.—A French East India company, founded in 1740, was broken up in 1770. A Danish East India company was founded in 1618, dissolved in 1634, reconstituted in 1670, and again dissolved in 1729. A new company, formed in 1732 under the name of the Danish Asiatic company, was prosperous during the 18th century, but has since declined, especially since 1845, when Denmark ceded Tranquebar and Serampore to Great Britain. A Swedish India company, established in Gottenburg toward the middle of the 18th century, and renewed in 1806, is still in existence; its operations, however, are inconsiderable. —The English endeavored to open commercial intercourse with India as early as 1553, during the reign of Edward VI.; but their expeditions sent out overland failed of reaching their destination, from want of geographical knowledge. The next attempts were made by sea, the belief being that a north-west passage about the upper part of the newly discovered American continent was practicable, and that this would give to England a channel to the Indies, over which the pope (who, in his capacity of chief of Christendom, had granted to the Portuguese the exclusive right to pass round the cape of Good Hope, a right which was long respected) would have no control, and which would enable them to compete successfully with the Portuguese. John Cabot, looking for India in 1497, had discovered Newfoundland. In 1553 his son Sebastian took charge of 3 vessels, to discover a north-east passage to India. This was sent out by a company chartered by Edward VI. with a capital of £6,000. In 1581 the English Turkish company endeavored, but without success, to pass overland to India. Meantime the desire for Indian wealth, the arbitrary closing of the Portuguese markets against British and Dutch, and the impossibility of going to India by the north, all conspired to make the British mer-

chants lose respect for the pope's bull and its prescribed boundaries, and to set out for India by the forbidden route. On Sept. 22, 1599, a company of London merchants was formed, representing a capital of £30,133, which received a charter from Queen Elizabeth, Dec. 31, 1600, under the title of the "Governor and Company of Merchants of London trading with the East Indies." The charter was for 15 years, and granted the exclusive right of trading to all countries from the cape of Good Hope eastward to the straits of Magellan, excepting those which were possessed by friendly European powers. The first Englishman who sailed to India by way of the cape of Good Hope was a Capt. Stephens, in 1582. Sir Francis Drake and Thomas Cavendish followed by way of Cape Horn. The latter sailed from England in July, 1586, in a small squadron fitted at his own expense, explored all the Indian ocean as far as the Philippines, and returned with a valuable stock of information in Sept. 1588. Two large Portuguese carracks laden with all the riches of the Indies fell into the hands of the English about 1593, and, beside rousing the cupidity and enterprise of their captors, were found to possess documents and charts of the greatest importance to the merchants shortly to adventure a trading expedition into unknown parts. These circumstances facilitated the formation of the company, of which Thomas Smythe, Esq., was the first governor, assisted by 24 directors named in the charter. The charter empowered them to elect a governor and directors and other office-bearers; to make by-laws for their government; to inflict punishments, corporal or pecuniary, on those in their employ, provided such punishments be within the laws of Great Britain; to export all goods duty free for 4 years, and to export foreign coins as bullion to the amount of £30,000 a year, £6,000 of the same being previously recoined at the mint; with the proviso, however, that they must import within 6 months from the conclusion of every voyage after the first an amount of specie equal to that before exported. It was also provided that should the company not be found to the public advantage, its charter might be cancelled after 2 years' notice given. There does not seem, after all, to have been very great zeal in fitting out vessels. Many of the stockholders did not pay up, and until 1613 but a small part of them united at all in the speculation, and these each on his own account, only using the ships of the company, and conforming to certain other regulations. The first expedition to India sailed under command of Capt. Lancaster, Feb. 15, 1601, from Torbay. It consisted of 5 ships, varying in size from 130 to 600 tons, having a cargo of bullion, iron, tin, broadcloths, cutlery, glass, &c. The entire venture, ships and all, was valued at £69,091. It arrived at Acheen, Sumatra, June 5, 1602. Lancaster made treaties with the kings of Acheen and Bantam, and returned to the Downs, Sept. 11, 1603, with a cargo of pepper and other produce, and a prize—a richly laden Portuguese carrack of 980 tons burden, taken with the aid of a Dutch vessel. For several years the expeditions were not increased in size or value, but were generally fortunate in their results. The profits for the first 8 years were stated at 171 per cent.; but when it is remembered that a voyage lasted from 2½ to 4 years, that long credits were given for goods sold, and that consequently it was often 6 to 8 years from the beginning of a voyage ere its accounts were settled, the profits were not so enormous as they look; and taking into consideration the real and the fancied risks, it is not surprising that the business of the company did not more rapidly enlarge. The profits of the trade with the islands were never very satisfactory, however. In 1607 Capt. Hawkins was sent out to endeavor to establish commercial intercourse with the dominions of the Great Mogul. His mission proved of no avail, the Portuguese intriguing successfully against him. In 1612 Capt. Beal obtained from the court at Delhi several considerable privileges, among which was that of establishing a factory at Surat, which city became at once the chief British station in India, until the organization of Bombay. Factories were depots for goods, fortified, in order to protect the lives and property of resident representatives of the company. They invariably proved the entering wedges for territorial aggrandizement on the part of the Europeans. In 1613 the capital of the company was united; the largest stockholders took the management of affairs, and these were so prosperous that in the course of 4 years the shares of the company rose to the value of 203 per cent., while its factories were extended to Java, Sumatra, Borneo, the Banda islands, Celebes, Malacca, Siam, the Coromandel and Malabar coasts, but chiefly to the dominions of the Great Mogul, whose favor the company had secured, after divers fruitless attempts. From the beginning of the company's trade to July, 1620, they had sent 79 ships to India, of which 34 had come safely home richly laden, 4 had been worn out in India, and 20 had been lost—2 by careening, 6 by sea perils, and 12 captured by the Dutch. At that time (1620) the capital of the company in ships, goods in India, &c., amounted to £400,000; they had exported from England to India the value of £840,376; had imported what cost £356,288 in India, which brought no less than £1,914,600 in England; and finally quarrels with the Dutch, their most energetic rivals, had occasioned losses to the amount of £84,088. In 1616 a new stock subscription had been opened, and £1,629,040 was raised. But in 1627 complaints were made of abuses and bad management in the company; during the reign of the Stuarts there was much murmuring against the monopoly, and Charles I. in 1635 gave to Sir William Courten and several private individuals the right to trade to India. In 1645 permission was given by the natives to the company to build Fort St. George at Madras. In 1655 Cromwell attempted, but vainly to make the

East India trade free. In 1657 he renewed the company's charter, which was confirmed by Charles II. in 1661, who at the same time conferred on them the further powers to make peace or war with any power not of the Christian religion; to establish fortifications, garrisons, and colonies; to export ammunition and stores to their settlements duty free; to exercise civil and criminal jurisdiction in their settlements according to English law; and to seize and send to England all Englishmen found trading on their private account. The years 1667–'68 witnessed the beginning of the tea trade—a branch of commerce which in a very few years proved to be of vast importance to the company. In 1669 the island of Bombay was granted to the company by Charles II., who had received it as part of the marriage portion of the princess Catharine of Portugal; but its possession was not secured without a long struggle between the English and the Portuguese residents. In 1676 a factory was established on the banks of the Hoogly, which formed the foundation of Calcutta; and other factories were shortly started in Bengal. In 1677 the company received a renewal of its charter, with indemnity for past misuses, and permission to establish a mint at Bombay. In 1681, by a report of the governor, the company had 35 ships, of from 100 to 700 tons, trading between India and England, or coastwise in India; and the exports from England of lead, tin, cloth, stuffs, &c., amounted to from £60,000 to £70,000 a year. The trade was astonishingly small; the affairs of the company were not prosperous, and in 1688 doubts were thrown upon the validity of its charter by the numerous interlopers and free traders to India. In 1693, after a heavy struggle, it received a renewal of its charter. In 1694 a vote of the house of commons threw open the trade to all England. In 1698 a new company received a charter (conferring much the same privileges as those of the old one), for the consideration of a loan of £2,000,000 to the state. The two companies could not live independently, and in 1702 they were united, under the title of "The United Company of Merchants trading to the East Indies." They advanced a further sum to the state, making in all a loan of £3,200,000, at 3 per cent., in consideration of which their charter was extended until the expiration of a notice of 3 years, which could not be given sooner than March, 1726, nor until the money borrowed by government should be repaid. The act ratifying this was passed in 1708. By it the local affairs of the company were intrusted to the 3 councils of Madras, Bombay, and Calcutta, while the general direction was retained in England. Meanwhile, in 1698 the company had acquired a grant of Calcutta and two adjoining villages, with right of jurisdiction over the inhabitants, and leave to erect fortifications, which was immediately done. In 1701 an act prohibited the importation into England of manufactured Indian goods. In 1715 an embassy to the emperor Feroksere obtained from him various highly important concessions for the company, among which were liberty for them to purchase the lordship of 37 towns contiguous to Calcutta, to sue and have given up to them all persons in Bengal indebted to them, and leave to pass goods for exportation duty free through the province. In 1732 the renewal of the charter was obtained with much difficulty. In 1744 the company bought its extension to 1780 by a loan of £1,000,000 at 3 per cent.—The political power of the British in India began in 1748. The acquisitions of the company were inaugurated in 1749 by its expulsion and ultimate protection of the rajah of Tanjore, he making some concessions of territory on each occasion of the British exercise of protection. In 1757 they deposed Surajah Dowlah, nabob of Bengal, gaining thereby several large and rich provinces. In 1761 the defeat of the French left the English free to pursue their schemes of aggrandizement in India. In 1792 Tippoo Sahib was compelled by Cornwallis to give up half his dominions, and £3,500,000 in bullion. In 1799 Seringapatam was taken, Tippoo slain, and some more territory annexed. Subsequently, by war with the Pindarees, with Burmah, Nepaul, the Afghans, &c., and by judicious protection, interference, and annexation, the company mastered the whole of Hindostan, with small exceptions. The sudden increase of territory and power in India threw every thing into confusion. Corruption reigned everywhere. The revenues fell short of expenses, and in 1772 the company, notwithstanding its immense possessions and privileges, was obliged to raise a loan of £6,000,000 from the bank of England, and of £1,400,000 from government, for current expenses. In 1773 reform was called for, but only incompletely effected. In 1781 the privileges of the company were extended to 1791, with 3 years' notice; the dividend on its stock was fixed at 8 per cent.; £400,000 was to be paid as an annual subsidy to the government, and ¾ of the surplus revenue after paying the subsidy was to go to the government, ¼ to the company's use. Yet in 1780 the East India trade formed only $\frac{1}{33}$ part of the entire foreign trade of the empire. In 1783 the company was again so involved, on account of wars, &c., as to be unable to pay the subsidy. In the same year, on the proposition of Mr. Pitt, a board of control was appointed. It consisted of such members of the British privy council as the sovereign of England chose to appoint, the 2 principal secretaries of state and the chancellor of the exchequer being 3 of the members. The president was usually a cabinet minister. The salaries of the president, paid commissioner, and secretary were paid by the company. In 1793 the charter was prolonged to 1814. From that date the charter was again prolonged 20 years, but the trade to India was substantially thrown open, though the monopoly of the trade to China was continued, and did not cease till 1834. Parliament in 1833 granted a new charter, by which: 1, the company ceased to be a trading

association; 2, it was continued in the government of India for 20 years, that is, until April, 1854, subject, however, to the authority of the board of control; 3, India was thrown open to the independent enterprise of British subjects; 4, all the property, real and personal, in possession of the company on April 22, 1834, was vested in the crown, and was to be held and managed by the company, in trust for the crown; the stockholders were assured by government an annual dividend of 10½ per cent. on the stock; 5, of the treasure of the company, valued in 1834 at £21,103,000, £2,000,000 was formed into a sinking fund, with the proceeds of which, in or after 1874, to buy out the stockholders at 200 per cent. valuation; £8,423,000 was consumed in the payment of the company's debts, and the balance was appropriated to various improvements in India; 6, the stock might be bought in by parliament at the rate of £200 for £100, any time after 1874, with the further condition that if at any time after 1854 the company were deprived by parliament of the government of India, stockholders may demand of parliament to purchase their stock, after 3 years' notice given. When, in 1854, the last charter of the company expired, it was determined by act of parliament to renew it, but not for any given time.—The capital stock, originally £2,000,000, had been increased at various times, till in 1793 it amounted to the sum of £6,000,000. At this it remained by law. This stock was owned in 1835 by 3,579 persons. As it was marketable, of course the number of stockholders continually changed. The ownership of stock to the amount of £1,000 (worth in 1835 £2,540) gave the privilege of one vote at the stockholders' meetings. The owner of £3,000 had two votes, of £6,000 three, of £10,000 and over, four. Women as well as men, and foreigners as well as Britons, if owning the requisite amount of stock, and present in London in person or by proxy, had the privilege of debating and voting. Stock must, however, have been held 12 months before the owner was entitled to a vote. In 1852 there were 2,583 voters, of whom 372 were women, 20 were peers of the realm, 10 members of parliament, 50 ex-directors, 86 clergymen, 19 physicians, 222 army officers, and 28 naval officers. Before 1836 the majority of the stockholders were merchants and bankers. The changes in the constitution, which extinguished the company as a trading association, caused a material lessening of the number of merchant stockholders. The stockholders met quarterly, in March, June, September, and December. Those owning £500 and upward of stock were permitted to be present. In 1835, 53 members had 4 votes, 54 had 3, 347 had 2, 1,454 had 1; 221, owning £500 each, were present without voting, and 396, owning smaller amounts, had no share whatever in the government. Special meetings could be called at any time at the instance of 9 holders of £1,000 each. Should the court of directors refuse to call a meeting after 10 days, the 9 stockholders took the matter in their own hands, and posted the call upon the pillars of the royal exchange. Voting was *viva voce;* the open ballot might, however, be called for by any 9 of the voting stockholders. The attendance was generally small, and in many important cases the directors, who were always present, had matters all their own way. Thus in 1854, a Mr. Levin brought before the stockholders' meeting the case of a judge in the Soodra court of Bombay, who had been dismissed by the court of directors. The question on reinstating the judge came up; 19 stockholders and 1 director were in favor of reinstatement, but 9 stockholders and 15 directors were against it, and the appeal fell to the ground. Thus the court of directors actually decided upon an appeal from themselves. A similar case occurred in 1856, when the same Mr. Levin opposed, in general meeting, the directors' donation of £5,000 to the marquis of Dalhousie. The court of directors was originally composed of 24 stockholders, qualified by the ownership of at least £2,000 of stock. Should a director sell out his stock, he ceased to hold office. Six were elected each year to serve for 4 years. After 12 months out of office members were eligible to reëlection. Directors must be British subjects. The act of 1853 changed the number and component parts of the court. It has since consisted of 18 members, of whom, by the act, 12 are elected by the stockholders, and 6 are chosen by the crown from men who have served a certain time in India. A third of each part go out of office each year, but may be immediately reappointed. In 1834 the court consisted of 10 former civil officers of the company, 4 army and 4 navy officers, 3 India merchants, and 9 bankers. Since then the number of London bankers has decreased, while the number of company men has increased. At that time (1835) 2 of the directors had held office 30 years, 2 between 20 and 30 years, 11 between 10 and 20, and 15 under 10 years. The directors choose annually from among themselves a chairman and deputy chairman, to serve one year each. The court meets once a week, and oftener if business requires. Nine members form a quorum. Absentees are fined 19*s.*, and the fines are divided once a year among the directors, so that even the absentees receive back a portion of their fines. Voting is by secret ballot. The deputy chairman is generally chosen chairman upon the expiration of his term of office. In case of a tie vote upon any question, the treasurer of the court decides the same by drawing lots. The directors had the initiative among the stockholders upon all questions of Indian government. For purposes of expediting business the members were annually divided into 3 committees: one on finance, and interior and marine interests connected therewith; the second on politics and war; and the third on the judicial and legislative interests. The chairman and deputy chairman were members of all these committees. The committees were formed according to seniority in the court; but after

the first meeting exchanges were permitted for good cause. The most important part of the court of directors, however, was the secret committee. To this, composed of the chairman, deputy chairman, and the senior director, were referred all communications of a confidential and delicate nature between the board of control (the chief power) and the court. The despatches of the board as to political matters were transmitted through the hands of the secret committee, and might be sent on by them without being submitted to the court. The members of this committee were sworn to secrecy, and had no secretary. The directors had a salary of £500, and the chairman £1,000. The chief privilege of directorship, however, was that of making appointments; the directors filled all vacancies, not only in the English branch of the company's service, but also in all the subordinate functions in India. They were thus enabled to provide for friends and relatives. The board of control, the governing power in the company, consisted at first of 6 members, but afterward the sovereign had the privilege of appointing what appeared to be a suitable number, of whom the lord president of the council, the lord privy seal, the first lord of the treasury, the two principal secretaries of state, and the chancellor of the exchequer, must form part. The president of the board received a salary of £3,500; two secretaries, who must be members of parliament, received £1,500 each. There were a number of assistant secretaries, writers, &c. The expenses of the board were limited to £26,000 per annum, paid by the East India company. The powers of the board gradually grew, until long before its abolition in 1858 it had become a court from whose decisions there was no appeal.—The total expense of the company's military force in the East Indies in 1856 was £10,229,584. The estimated receipts of the home treasury for the year ending April 30, 1858, amounted to £11,649,387 (including the balance from the old account), and the disbursements to £8,930,330, leaving an estimated balance in favor on April 30, 1858, of £2,719,057. The debts of the Indian government in England on May 1, 1857, amounted to £9,377,401, and the credits to £5,488,467, leaving a surplus of debts of £3,888,934. The establishment of the company in England entailed a yearly charge of £133,622 for 525 employees, and the amount of new or increased salaries created or granted between May 1, 1856, and May 1, 1857, was £6,467.—The recent disturbed state of the British possessions in the East in 1857–'8 called public attention more forcibly than at any previous period to the management of Indian affairs by the company; and after much discussion on the subject in parliament and in the press, an act "for the better government of India" was passed, Aug. 2, 1858, by which "all the territories heretofore under the government of the East India company are vested in the British queen, and all its powers are to be exercised in her name, one of the principal secretaries of state to have all the powers hitherto exercised by the company or by the board of control. The military and naval forces of the East India company are to be deemed the forces of the queen, and all persons holding any office, employment, or commission in India are transferred to the service of the crown. All functions and powers of the courts of directors and proprietors are to cease, together with the salaries paid, and the board of control is likewise abolished." This act, however, although depriving the East India company of all its power and importance, does not abolish it, and provides for the manner in which the directors shall hereafter be appointed; but its functions are now almost exclusively confined to the administration of the stock and the distribution of the fixed interest or dividends upon the old share capital of the proprietary body of the company.

EAST INDIES, a vague geographical term applied to southern Asia east of the Indus, and to the adjacent islands. The name India is unknown to the people of the countries so designated, and was derived by the languages of modern Europe from the Greeks, who probably borrowed it from the Persians; and it is doubtless a modification of the Sanscrit *Sindhu*, the appellation of the Indus and of the people on its banks. It was unknown to the earlier Greeks, and is mentioned neither by Homer, Pindar, nor the great dramatists. The later Greeks used it to signify an indefinite extent of country lying beyond the Indus, of which they had a very imperfect knowledge. The modern Europeans applied it in much the same way until after the discovery of America. Columbus supposed that he had reached India by sailing westward, and the lands discovered by him and the other Spanish navigators in the western hemisphere were for a time collectively known as India. The king of Spain assumed the title of king of the Indies, and the council for the colonies was styled the supreme council of the Indies. When the mistake was discovered, the distinctive term West Indies was applied to America, and that of East Indies to Asiatic India. In process of time the term West Indies became restricted to the islands lying between North and South America, and the term India to the two peninsulas of Hindostan and Further India, or India beyond the Ganges. The latter country is also called Chin-India or Indo-China, and in its most restricted sense the term India now includes only Hindostan. The term East Indies, as vaguely and popularly used, comprises Hindostan, Burmah, Siam, Laos, Anam, Malacca, Ceylon, Sumatra, Java, Borneo, Celebes, the Sunda and Banda islands, the Moluccas, the Philippines, and the rest of that vast archipelago, and is sometimes extended even to China and Japan.

EAST RIVER, a strait about 18 miles long, and between New York and Brooklyn about ¼ of a mile wide, connecting New York bay with Long Island sound. It leaves the sound at a point called Throg's neck, where there is a lighthouse with a fixed light, and where the

strong fortress of Fort Schuyler defends the E. approach to New York; and it enters the bay to the S. E. of Manhattan island, between the metropolis and Brooklyn. It also communicates with the Hudson by a narrow channel called the Harlem river, which forms the N. boundary of Manhattan island. It has a rapid current caused by the tide from the Atlantic, which, gathering force as it flows W. into the narrowest part of the sound, reaches its greatest height in the East river, arrives at New York ¼ of an hour earlier than that which rises in the bay, and drives upward along the E. shore of the Hudson many miles in advance of the tide on the W. shore. The East river is navigable by vessels of the largest size, and is crossed by numerous steam ferries. It contains several islands, and has a pass called Hellgate, 7 m. from New York bay, the navigation of which is attended with considerable danger. Some of the most serious obstructions have recently been removed by a new method of blasting, which consists of simply exploding the powder on the rock by means of an electric spark, the superincumbent mass of water acting with a resisting force powerful enough to break the rock without the necessity of boring.

EASTBURN, James Wallis, an American author, born in England in 1797, died on the passage from New York to Santa Cruz, Dec. 2, 1819. He was graduated at Columbia college, New York, and subsequently studied theology under Bishop Griswold at Bristol, R. I., with a view of taking orders in the Protestant Episcopal church. While thus employed, with occasional assistance from Robert C. Sands, a former college associate, he undertook a new metrical version of the Psalms, which he did not live to complete. At the suggestion of Eastburn the two friends commenced, in Nov. 1817, and finished before the succeeding summer, "Yamoyden," a romantic poem founded on the history of King Philip, the sachem of the Pequots. With many marks of youth and inexperience, it has merits of a high order, and for a joint production of juvenile authors may be considered a remarkable performance. He also wrote several fugitive poems, some of which are very gracefully versified. In 1818 Mr. Eastburn was ordained, and left New York to take charge of a parish in Accomac, Va. Failing health interfered with the discharge of his duties, and he sailed from New York for Santa Cruz to try the effects of a change of climate, but died a few days after embarking.

EASTBURN, Manton, D.D., an American clergyman, brother of the preceding, bishop of the Protestant Episcopal church in Massachusetts, born in England, Feb. 9, 1801. His parents came to the United States when he was a boy, and settling in New York, he was educated in that city, and was graduated at Columbia college in 1817. After suitable preparation, he was ordained in May, 1822, was assistant minister of Christ church, New York, for a few years, became rector of the church of the Ascension in 1827, and gathered under his ministry a large and influential congregation. He was consecrated assistant bishop of Massachusetts in Trinity church, Boston, Dec. 29, 1842, and on Bishop Griswold's death, Feb. 15, 1843, became bishop of the diocese. Dr. Eastburn was appointed lecturer on poetry in Columbia college, but declined the appointment; in 1825 he delivered 4 lectures on Hebrew, Latin, Italian, and English poetry before the New York Athenæum; in 1829 he contributed a portion of a volume of "Essays and Dissertations on Biblical Literature;" in 1833 published his "Lectures on the Epistles to the Philippians," a volume which met with considerable favor; and in 1837 he delivered the oration at the semi-centennial anniversary of the incorporation of Columbia college. He has edited Thornton's "Family Prayers."

EASTER, the festival of the resurrection of our Lord, or the Christian passover. The English name Easter and the German *Ostern* have been supposed by some writers to be derived from the name of the feast of the Teutonic goddess Ostera (the goddess of spring), which was celebrated by the ancient Saxons in the spring, and for which the early missionaries substituted the Christian festival. According to Adelung, both the English and the German words are derived from the old Saxon word *oster*, *osten*, which signifies rising, because nature arises anew in the spring. According to the Mosaic law, the passover among the Jews was celebrated on the 14th day of the month Abib, afterward called Nisan, that is, within a day or two before or after the vernal equinox. The early Christians differed in regard to the time of celebrating Easter. The churches in the West, taught, as they declared, by St. Philip and St. Paul, observed the nearest Sunday to the full moon of Nisan, without taking account of the day on which the passover was celebrated. The Asiatic churches, on the other hand, in accordance as they said with the tradition derived from St. John, followed the Jewish calendar, and adopting the 14th of Nisan as the day of the crucifixion, celebrated the festival of Easter on the 3d day following, whatever day of the week that might be. From this circumstance they were called Quartodecimans. The dispute on this point in process of time became serious, and neither side was able to convince or convert the other. The venerable Polycarp, bishop of Smyrna, went to Rome, A. D. 158, and had a conference with Anicetus on this subject. Forty years later, Victor, bishop of Rome, was appealed to, and was very peremptory in requiring the Asiatic bishops to conform to the rule of the western church. This they refused to do, and Polycrates of Ephesus, in behalf of his brother bishops, sent Victor word that they had resolved to maintain the custom which they had received from their fathers. Victor then went so far as to break off communion with the eastern churches, for which he was rebuked by St. Irenæus of Lyons. After this the contending

parties agreed to maintain their respective customs and practices on this subject, without censuring one another. Saving occasional disputes, matters continued in this state until the time of Constantine, who had the subject brought before the council of Nice (A. D. 325). The question was fully discussed, and finally settled for the whole church by adopting the rule which makes Easter day to be always the first Sunday after the full moon which happens upon or next after March 21; and if the full moon happen on a Sunday, Easter day is the Sunday after. By this arrangement Easter may come as early as March 22, or as late as April 25.—This sacred festival has been termed the queen of festivals; it has been observed from the very beginning, and it is celebrated in every part of the Christian world with great solemnity and devotion. The primitive Christians very early on the morning of Easter saluted each other with the words: "Christ is risen;" to which the response was made: "Christ is risen indeed, and hath appeared to Simon." The Greek church still retains this custom. In nearly all Christian countries the recurrence of Easter has been celebrated with various ceremonies, popular sports, and superstitions. Among the best known is the English custom of making presents of colored eggs, called pasche or paste eggs, which were often elaborately ornamented; and in a royal roll of the time of Edward I., preserved in the tower, appears an entry of 18*d.* for 400 eggs to be used for this purpose. Colored eggs were used by children at Easter in a sort of game which consists in testing the strength of the egg shells, and this practice is retained in many places in England and the United States. In some parts of Ireland the legend is current that the sun dances in the sky on Easter Sunday morning. This was once a prevailing superstition in England also, which Sir Thomas Browne, the author of "Inquiry into Vulgar Errors," thought it not superfluous to declare unfounded. The game of ball was a favorite Easter sport, in which municipal corporations formerly engaged with due parade and dignity; and at Bury St. Edmund's within a few years the game was kept up with great spirit by 12 old women. In the northern counties of England on Easter Sunday the men parade the streets and claim the privilege of lifting every woman 3 times from the ground, receiving in payment a kiss or a silver sixpence. The same is done by the women to the men on the next day. In a part of Oxfordshire, after evening service on Easter Sunday, men and women used, as late as 1822, to throw great quantities of apples into the churchyard, and those who had been married during the year threw 3 times as many as the rest; after which all went to the minister's house and feasted on bread, cheese, and ale. A less innocent custom once prevailed in France of stoning Jews at this season; and Dulaure in his "History of Paris" tells us that Aimeric, viscount de Rochechouard, having visited Toulouse at Easter, the chapter of St. Étienne appointed his chaplain Hugues to beat a Jew in his honor, an office which was performed so zealously that the victim expired on the spot. In England it was common for the boys to run about the streets on Easter morning crying:

> Christ is risen, Christ is risen;
> All the Jews must go to prison.

To mark their abhorrence of Jews, the English used also to make a point of eating bacon on this festival, but with it they had tansy pudding, a relic of the bitter herbs of the passover.

EASTERN EMPIRE. See BYZANTINE EMPIRE.

EASTLAKE, SIR CHARLES LOCK, an English painter, born in Plymouth in 1793, studied under Fuseli at the royal academy, London, of which institution he was made president in 1850, after having given evidences of proficiency in his art by a great variety of pictures, of which his "Christ weeping over Jerusalem," his "Escape of Francesco di Carrara," and his "Pilgrims arriving in sight of Rome," are the best. He visited France, Italy, and Greece, and then settling for some time in Rome, found many opportunities for painting pictures illustrative of Italian life. Among his early paintings is an interesting portrait of Napoleon I., as he appeared on board the Bellerophon, and the most famous of his poetical pictures is an illustration of a passage in Byron's "Dream." In 1850 he was knighted, and in 1855 appointed director of the national gallery, with a salary of £1,000. He has translated Goethe's *Farbenlehre* into English, and written much on art. He married Miss Elizabeth Rigby, author of "Letters from the Shores of the Baltic" (1841), "Livonian Tales" (1846), and other writings.

EASTMAN, CHARLES GAMAGE, an American poet and journalist, born in Fryeburg, Me., June 1, 1816, removed at an early age with his parents to Barnard, Vt., in 1829 commenced his preparatory studies at the academy in Royalton, Vt., continued them at Windsor, and finished them at Burlington, in 1837. He was principal editor of the Burlington "Sentinel" in 1835–'6; commenced the "Lamoille River Express" newspaper at Johnson, Vt., in the spring of 1838; established the "Spirit of the Age" at Woodstock, Vt., in 1840; and purchased the "Vermont Patriot" and removed to Montpelier in 1846. He was postmaster at Woodstock and Montpelier for several years, senator for Washington county in 1851–'2, district delegate to the democratic national convention in 1852, candidate for elector and delegate at large to the national convention in 1856, and candidate for congress in 1858. He published a volume of poems in 1848, which was well received by the public. He has been until of late years a liberal contributor of poetry to reviews and magazines, and his poems pronounced at Dartmouth, university of Vermont, and other colleges, have gained a high reputation. He resides at Montpelier, and continues to be editor and proprietor of the "Vermont Patriot."

EASTMAN, Mary Henderson, an American authoress, born in Warrenton, Fauquier co., Va., about 1817. She was married in 1835 to Capt. Seth Eastman, of the U. S. army, with whom she resided for many years at Fort Snelling, Min., and at other frontier stations. She has published "Dacotah, or Life and Legends of the Sioux" (New York, 1849); "Romance of Indian Life" (Philadelphia, 1852); "American Aboriginal Portfolio" (1853); and "Chicora and other Regions of the Conquered" (1854). In 1852 Mrs. Eastman published "Aunt Phillis's Cabin," intended as a reply to Mrs. Stowe's "Uncle Tom's Cabin," and which reached a sale of 18,000 copies in a few weeks. She is also the author of "Tales of Fashionable Life," and of many tales and sketches for "Arthur's Home Magazine," and other periodicals.

EASTON, a borough and the capital of Northampton co., Penn., on the right bank of the Delaware river, between the mouths of Lehigh river and Bushkiln creek, 56 m. N. from Philadelphia; pop. in 1859, about 10,000, exclusive of the adjoining borough of South Easton and village of Glendon, on the opposite bank of the Lehigh, containing not less than 3,000 inhabitants. Excepting the eastern part of the town, the site is hilly, but the plot is nevertheless very regular, and the streets are wide and at right angles. The town has a public square, is lighted with gas, and supplied with water from a spring at a distance of one mile, and from the river. The height of reservoirs on the surrounding hills is so great that in a large portion of the town fires are extinguished without the aid of engines. The Delaware is spanned by 2 bridges, one of them a handsome railroad bridge of wood about to be replaced by iron, and the other a fine wooden bridge 570 feet long, erected at a cost of $80,000. Bushkiln is spanned by 3 long and substantial stone bridges and one of wood, and the Lehigh by 2 fine wooden bridges. Beside an extensive high school, an academy, and 2 other schools, situated on a tract of land set apart perpetually for educational purposes, Easton contains several other academies, &c., and a public library of 4,000 vols. It is also the seat of Lafayette college founded in 1832 with its normal school, having in 1858 6 professors, 100 students, and a library of 4,500 vols. There are 2 banks with an aggregate capital of $500,000; 5 weekly and 2 daily newspaper offices; 11 churches (1 Baptist, 1 Dutch Reformed, 1 Episcopal, 1 German Reformed, 2 Lutheran, 1 Methodist, 2 Presbyterian, 1 Roman Catholic, 1 Universalist), and 2 Jewish synagogues. A handsome cemetery of 40 acres was commenced in 1849 on picturesque and broken ground overhanging the Bushkiln creek, in which is erected a monument over the remains of George Taylor, one of the signers of the declaration of independence, who lived and died in Easton. There is also a farmers' and mechanics' institute, incorporated in 1856, whose buildings and grounds, erected and prepared at considerable expense, cover 30 acres, where fairs are annually held. Being the outlet of a rich agricultural country, Easton has always manufactured, and formerly exported, a large amount of agricultural products, which at this time are more generally absorbed by home consumption. As late as 1851, however, it exported over 110,000 barrels of flour, 50,000 barrels of corn meal, and 14,000 barrels of whiskey. In 1850 there were in the town, and within a few miles circuit, 18 grist mills, 6 saw mills, 1 planing mill, 3 oil mills, 3 tanneries, 5 founderies, 2 large blast furnaces, 1 wire factory, 7 distilleries, 2 cotton factories, and 2 rifle factories. The surrounding country contains inexhaustible deposits of the best iron ore, which is largely manufactured here; and within 12 miles are found large deposits of the best zinc ore, which is manufactured near the mines. In the immediate vicinity of Easton are 3 large blast furnaces, which manufacture about 30,000 tons of pig iron annually. Easton is at the terminus of the celebrated Lehigh valley, which is the route through which the Lehigh canal and Lehigh valley railroad penetrate the great anthracite coal formation. The avenues from Easton to market are the Delaware river, Delaware canal, Belvidere Delaware railroad, and Lehigh valley and north Pennsylvania railroads to Philadelphia, and the Morris canal and central railroad of New Jersey to New York. By the Warren railroad and the Delaware and Lackawanna railroad it has unbroken communication with the railroads of New York and with the lakes. The borough was laid out in 1738 and incorporated in 1789. The Six Nations and 7 other Indian tribes met here in council in 1758 with the governors of Pennsylvania and New Jersey and Sir William Johnston. Gen. Washington made it in the revolution a place of deposit for numbers of British prisoners; and in 1779 Gen. Sullivan made it the rendezvous of a body of troops previous to his campaign against the Indians.

EASTPORT, a township of Washington co., Me., situated upon the boundary line between that state and the province of New Brunswick; pop. in 1858, 4,650. Its area is little more than 3 sq. m., comprising Moose island and several smaller islands in Passamaquoddy bay. It was incorporated in 1798. The village is compactly built on the S. E. shore of Moose island, and communicates with the mainland by a covered bridge 1,200 feet long to Perry, and by ferries to Lubec and other places. It has a spacious harbor, in which the tides rise over 25 feet, and which is never blocked up by ice. In the season of navigation steamers run daily up the river St. Croix to St. Andrew's and Calais, and semi-weekly to Boston, Portland, and St. John, N. B. It contains 7 churches, 6 large school houses, a bank, a railway for repairing vessels, gas works, a weekly newspaper office, and a public library. The trade with the neighboring British provinces is large, ship-building is an important branch of industry, and lumber is exported in considerable quantities. It is also the centre of an extensive fishing business; at

times 200 or 300 boats may be seen employed in fishing within sight of the town, and large quantities of herrings are taken in weirs about the shores of the bay. Easton is the port of entry for the extensive collection district of Passamaquoddy. A fine brick and stone custom house was built by the federal government in 1850 at an expense of $36,500. The shipping of the district amounted, on June 30, 1858, to 17,490 tons registered, and 7,736 tons enrolled and licensed. On July 11, 1814, the place was captured by a British force under the command of Lieut. Col. Pilkington and Capt. Sir Thomas Hardy. It was claimed as included in the original limits of the province of New Brunswick, and the British commissioners at Ghent refused to agree to the surrender of the islands in Passamaquoddy bay. The matter was referred to another commission, and on June 30, 1818, the place was surrendered to the United States. During the 4 years of military occupation it was governed by martial law. Fort Sullivan, which stands on a hill in the midst of the village, is now without a garrison.

EATON, a central co. of Mich., intersected by Grand river; area, 576 sq. m.; pop. in 1850, 7,058. The surface is undulating; the northern and middle parts are occupied by dense forests, and in the south are plains over which are scattered oak trees. The soil is generally a deep calcareous and sandy loam, suitable for grain, potatoes, maple sugar, and pasturage. The productions in 1850 were 50,860 bushels of wheat, 73,212 of Indian corn, 44,290 of oats, 7,207 tons of hay, 23,769 lbs. of wool, and 210,167 of maple sugar. There were 2 churches, 1 newspaper office, and 2,192 pupils attending public schools. Capital, Charlotte.

EATON, a post village of Washington township, and capital of Preble co., Ohio; pop. in 1853, about 1,600. It is situated on a fine mill stream called Seven Mile creek, in the centre of a rich agricultural country, 46 m. from Cincinnati, with which city it has communication by means of the Eaton and Hamilton railroad. About one mile W. from Eaton is the site of Fort St. Clair, which was built during the winter of 1791–'2. General Harrison, then an ensign, commanded the guard during its erection. The village was laid out in 1806.

EATON, Horace, governor of Vermont, born in Barnard, Windsor co., Vt., June 22, 1804, died in Middlebury, Vt., July 4, 1855. He was graduated at Middlebury college in 1825, received the degree of M.D. in 1828, and practised medicine at Enosburg, Vt., from 1828 to 1848, when he accepted the professorship of chemistry and natural history in Middlebury college, performing its duties until the autumn of 1854, when he resigned by reason of ill health. He was repeatedly a member of the state legislature, was lieutenant-governor of Vermont in 1843, and twice reëlected, and was governor of Vermont from 1846 to 1848. From 1845 to 1850 he was state superintendent of common schools. He was a member of the constitutional convention in 1843. He published several literary and political addresses, and educational reports.

EATON, William, an American soldier, born in Woodstock, Conn., Feb. 23, 1764, died in Brimfield, Mass., June 1, 1811. At 16 years of age he cloped from home, and enlisted in the American revolutionary army, from which he was discharged in 1783. In 1790 he was graduated at Dartmouth college, and two years later received a captain's commission in the U. S. army. After remaining several years in the service, he was appointed, in the summer of 1797, American consul at Tunis, but did not depart for that place until Dec. 1798. He arrived at the scene of his new duties in March, 1799, and for several years was engaged in a series of negotiations and altercations with the bey, having reference to the annual payment of tribute money. In this difficult position he acted with a boldness and tact which secured to the commerce of his country an immunity from the attacks of Tunisian cruisers. Upon the commencement of hostilities between the United States and Tripoli in 1801, Eaton conceived the idea of inducing Hamet Caramelli, the rightful bey of Tripoli, who had been deposed by his brother, to organize a land force for the purpose of coöperating with the American fleet in its attack upon the city. Finding the American naval officers averse to this project, he resigned his consulship, and in 1803 returned to the United States. He was unable to procure there the means to prosecute his scheme successfully, but received the appointment of navy agent of the United States for the Barbary states. Although very slight powers were attached to this office, he accompanied the American fleet to the Mediterranean in the summer of 1804. Learning that Hamet Caramelli, after a series of reverses in an attempt to recover his throne, had taken refuge in Egypt, he sought him out, and in the early part of 1805 assisted him in assembling a force of about 500 men, four-fifths of whom were Arabs, the remainder being Christian adventurers, principally Greeks, with 9 Americans. Having secured the coöperation of the American fleet, the little army, under the command of Eaton, took up its march across the Libyan desert for Derne, the capital of the richest province of Tripoli, a distance of about 600 miles. On several occasions the mutinous disposition of the Arab sheiks, and the irresolution of Hamet, imperilled the safety of the handful of Christians belonging to the expedition; but the energy and courage of Eaton triumphed over all obstacles, and the forces were brought in safety to Bomba, on the coast, where the American ships Argus and Hornet were in waiting. On April 25 Eaton encamped before Derne, and on the 27th, with the assistance of the ships of war, attacked and carried the city after a furious assault, in which he was wounded. A few days later an army of several thousand Tripolitans, despatched by the reigning bey, approached

the town, and for several weeks occasional sharp skirmishes took place between the opposing forces, Eaton's army having meanwhile been considerably augmented. On June 11 a general engagement was fought, in which several thousand men took part, and the enemy were totally routed, and driven back to the mountains. At this moment, when Eaton was preparing by a rapid march to fall upon Tripoli, reinstate Hamet on the throne, and release the American captives detained there without ransom, intelligence arrived that a peace had been concluded by Col. Tobias Lear, the American consul-general at Algiers, one of the conditions of which was that $60,000 should be paid the bey for the ransom of the Americans. Eaton soon after returned to the United States, where he received many marks of popular favor. The president spoke of him in flattering terms in his annual message, and the legislature of Massachusetts voted him a tract of 10,000 acres of land, in acknowledgment of his services. The remainder of his life was passed in Brimfield, Mass., which town he at one time represented in the state legislature. According to his testimony given on the trial of Aaron Burr, he was solicited by the latter to embark in his project of establishing a southern empire, but declined. Habits of inebriety grew upon him in his latter years, and hastened his death. Eaton was a well informed man, and from his official and private correspondence appears to have possessed a strong, nervous style, and graphic powers of description. A memoir of him was published in Brookfield, Mass., in 1813; and another by Prof. C. C. Felton, compiled from his original papers, is contained in Sparks's "American Biography."

EAU DE COLOGNE, alcohol perfumed with essential oils, named from the city of Cologne, in which its manufacture is extensively prosecuted, and from which several million bottles are annually exported. The inventor and most famous maker was Jean Marie Farina; but his name is now adopted by several of the manufacturers of Cologne, and in other countries it is attached to very different preparations, resembling the genuine only in the bottles and labels, which are perfect copies of the original. Numerous recipes are given for this preparation, some of which are stated to have come from Farina himself. Most of them are very complicated from the great number of ingredients. Purity of the volatile oils, and also of the alcohol, and freedom especially of the latter from fusel oil, are essential to the perfection of the perfume. It is also important that no one of the volatile oils should so predominate that its odor may be perceived above the rest. Distillation after mixing is recommended in some cases, and in others condemned, as the volatile oils do not distil over so readily as the spirit, and therefore a portion of their strength is lost by the process. When not distilled, the mixtures should stand for some weeks or months, that the oils may be thoroughly dissolved in the alcohol. The following is given as the process of Farina in the *Dictionnaire des arts et manufactures:* balm and mint of Notre Dame, each 350 grammes; petals of roses and violets, each 120 gram.; lavender flowers, 60 gram.; absinthium (wormwood), 30 gram.; sage and thyme, each 30 gram.; orange flowers, nutmegs, mace, cloves, and cinnamon, each 15 gram.; camphor and angelica root, each 8 gram. These ingredients are digested in 660 lbs. avoirdupois of rectified alcohol for 24 hours, adding 2 lemons and 2 oranges cut into slices. The mixture is then distilled by heat of the sand bath until 440 lbs. have passed over. To this product are then added essences of lemon, of cedrat, of balm, and of lavender, each 45 gram.; essences of neroli and of rosemary, each 15 gram.; essence of jasmine, 30 gram.; essence of bergamot, 350 gram. The whole are thoroughly mixed and then filtered. It is also prepared without distillation, but the odor is never so fine. Lebeaud and Fontenelle (*Nouveau manuel complet du distillateur et du liquoriste*, Paris, 1843) recommend the following: dried rosemary, thyme, sweet marjoram, wormwood, balm, and hyssop, 1 oz. each; cloves, cinnamon, angelica root, juniper berries, anise, cummin, fennel, and caraway seeds, fresh orange peel, and oil of bergamot, 1 oz. each; cardamoms, lavender flowers, and bruised nutmegs, each 2 oz.; the whole to be digested in 10 quarts of alcohol several days, and then distilled to dryness by water bath. Or, to the same quantity of alcohol may be added 1 quart each of tincture of balm and rosemary; 2 oz. each of oil of bergamot, rosemary, citron, and cedrat, and 1 dram of oil of orange flowers. This may be improved by the further addition of 2 oz. each of essence of roses and of jasmine, and 1 dram of oil of cloves. Distillation is not essential in this case. Dr. Brande gives the following method of preparing a good imitation: alcohol, 1 pint; orange flower water, 1 pint; oils of bergamot, orange peel, and rosemary, each 1 drachm; and bruised cardamoms, 1 drachm. From this mixture 1 pint is to be distilled by water bath.

EAU DE LUCE (*aqua luciæ*), a kind of liquid soap made by mixing a little oil of amber and mastic or balm of Gilead with ammonia. It is merely scented ammonia. It is esteemed a remedy for the bites of poisonous animals. The compound tincture of ammonia is substituted for it, made by dissolving 2 drachms of mastic in 9 fluid drachms of rectified spirit; pouring off, and adding a pint of strong ammonia, and 14 minims of oil of lavender.

EBAL AND GERIZIM, mountains in Palestine. These 2 mountains are within 200 paces of each other, and separated by a deep valley, in which stood the old city of Shechem, now Nabloos. They are much alike in size and form, being semi-circular in figure, from 700 to 800 feet in height, about half a league in length, and on the sides nearest Shechem nearly perpendicular. They were made memorable by the solemn ratification of God's covenant with the

Jews after they had passed over Jordan, when 6 tribes were placed on Gerizim and 6 on Ebal, the former to pronounce blessings on those who should faithfully keep the divine law, and the latter to pronounce curses on those who should violate it; whence they were known as the mount of blessing and the mount of cursing. (Deuteronomy, xxvii. and xxviii.) According to the injunction of Moses, the Jews after obtaining possession of Canaan built an altar and celebrated a feast on Ebal. This, the Samaritans contended, should have been done on Gerizim, and they afterward built a temple on the latter, the ruins of which are still visible, and regarded it as the Jews regarded their temple at Jerusalem. The remark of the Samaritan woman to Christ at Shechem (John iv. 20) is in allusion to this difference of opinion as to the proper place of worship.

EBELING, Christoph Daniel, a German scholar, born near Hildesheim, Hanover, in 1741, died in Hamburg, June 30, 1817. He was noted for his extensive knowledge of oriental languages, of classic and foreign literature, and of history and geography. He published a history and geography of North America (7 vols., Hamburg, 1796–1816), for which he received a vote of thanks from the U. S. congress. He paid special attention to the geography of the new world, and collected about 10,000 maps and nearly 4,000 books, all relating to America. This library was purchased in 1818 by Mr. Israel Thorndike of Boston, and presented by him to Harvard college, where it now is.

EBENEZER, the name of the field in which the Israelites were defeated when the ark of God was taken (1 Sam. iv. 1), and also of a memorial stone or monument set up by Samuel to commemorate their victory over the Philistines at Mizpeh, when God interposed for their deliverance (1 Sam. vii. 5–12). The compound word signifies the stone of help, and was probably not applied to the field before the second event. The monument was erected by the prophet, saying: "Hitherto hath the Lord helped us." Hence it is often said: "Here will we set up our Ebenezer," *i. e.*, will establish some memorial of the divine faithfulness and goodness.

EBERHARD IM BART (Eberhard with the Beard), the 1st duke of Würtemberg, born Dec. 11, 1445, died Feb. 14, 1496. His early life was signalized by great irregularities; his father, Count Louis the Elder, dying while he was young, his education was neglected, and before he was 14 he wrested the government from his uncle Ulric, who had been appointed regent during his minority. A pilgrimage to the Holy Land, however, and the influence of his wife, the princess Barbara of Mantua, had a happy effect upon his character. He became eventually celebrated in German history as the founder of the undivided sovereignty and of the representative constitution of Würtemberg. He devoted himself to study, promoted science and literature, and founded in 1477 the university of Tübingen. He improved the laws and the condition of the convents in Würtemberg, and was a friend of peace, without however shrinking from war. The emperor Maximilian of Germany, who conferred on him the title of duke of Würtemberg (1495), declared at his grave several years afterward: "Here lies a prince who has left no equal in the German empire in princely virtues, and whose advice I have frequently followed with advantage."

EBERHARD, Johann August, a German philosopher, born in Halberstadt, Aug. 31, 1739, died Jan. 7, 1809. At first a teacher, he afterward became a pastor, and was one of the first and principal of the German rationalists. In a work entitled *Neue Apologie des Sokrates* (3d ed., Berlin, 1788), he opposed with great vigor and with what was deemed dangerous latitudinarianism the opinion which had been lately advanced that the virtues of the pagans were only splendid vices. A religious romance entitled *Amyntor* did not, as it was designed to do, cause the temerities of this apology to be forgotten. In 1778 he was appointed professor of philosophy in the university of Halle, and soon after a member of the academy of Berlin. He was attached to the philosophy of Leibnitz and Wolf, and combated more zealously than successfully the systems of Kant and Fichte. Though his learning was as superficial as it was extensive, and he was rather a rhetorician and historian than a philosophic thinker, he was yet a brilliant and elegant writer. He predicted that the "Critique of Pure Reason" would be in the future only a curious document for a history of the aberrations of the human mind, and he was one of the few adversaries whom Kant honored with a reply. He had affirmed that the critical philosophy was found in other systems, particularly that of Leibnitz, and Kant vanquished but did not silence him by proving that he did not understand Leibnitz. Eberhard maintained the simplicity and identity of the thinking and feeling faculty, the soul being, according to him, active when it thinks, passive when it feels. His writings upon philosophical and æsthetical subjects are numerous.

EBERHARD, Konrad, a German artist, born in 1768, died in Munich, March 13, 1859. The ex-king Louis was his patron, and sent him in 1806 to Rome, where he laid the foundation of his reputation. In 1816 he became professor of sculpture in the academy of fine arts at Munich. He also painted many pictures illustrating the conflicts, progress, and triumphs of the Christian religion. Among his best works are the tomb of the princess Caroline in the *Theatinerkirche*, and the statues of St. George and St. Michael before the Isar gate in Munich.

EBIONITES, a party in the early Christian church. The name was first used to designate all in the church who held to Jewish opinions or practices. Its origin is disputed. Tertullian maintained that one Ebion, a Samaritan Jew, contemporary with the apostle John, was the founder of the sect. But the existence of any

such man is now generally questioned, and the explanation which Origen gives that the word comes from the Hebrew אביונים, "poor people," is accepted by most critics. Until the 4th century the Ebionites seem to have been identical in practice with the sect of the Nazarenes, and the two sects are in the writings of the fathers frequently confounded. The doctrine of the Ebionites was a mixture of Judaism and Christianity. While they accepted the Old Testament in its integrity, they rejected the New Testament, substituting a gospel based upon the facts in the Gospel of Matthew. This gospel was known to the primitive Christians as the "Gospel of the Hebrews." The Ebionites denied the divinity of Christ, retained the practice of circumcision while observing baptism and the Lord's supper, kept the 7th day of the week as a sabbath, and conformed themselves in many things to the ascetic discipline of the Essenes. Their opinions were afterward somewhat modified, and they were divided particularly in their dogma concerning the birth of Jesus and the method of his union with God. As Epiphanius represents them, they believed that Jesus was the incarnation of an exalted superangelic spirit, who came to republish the law which Moses had published before, and which was the law of right and truth given to the original Adam. They were opposed to the doctrine of priestly and monastic celibacy. They interpreted literally the Hebrew prophecies in regard to the Messiah's kingdom, and expected that material reign of Christ which Isaiah describes. The residence of the Ebionites was chiefly in the neighborhood of Jerusalem.

EBN. See Aben.

EBOLI, Anna de Mendoza, a Spanish princess of the 16th century, the daughter of a viceroy of Peru. At an early age she was introduced at the court of Philip II. by her husband the prince of Eboli, a favorite of the king and preceptor of his son Don Carlos. Though one of her eyes was defective, her beauty attracted general attention, and she became noted for her amorous as well as political intrigues. Foremost among her admirers were the king and his secretary of foreign affairs, Antonio Perez. She was implicated in the assassination of Escovedo, the envoy of Don John of Austria.

EBONY (*diospyros ebenum*, Willdenow), a tree with hard, heavy wood, native of the East Indies. The black ebony, the most highly prized, grows spontaneously in Ceylon, Madagascar, and Mauritius. There are other colors, however, such as green, red, yellow, and white and black striped. There is another kind called ironwood from its intense hardness. The heart wood of *D. reticulata*, a lofty tree in Mauritius, is also esteemed. The ebony of the Coromandel coast is derived from *D. melanoxylon* (Roxburgh). Ebony is likewise procured from *D. tomentosa* and *D. Roylei* of the East Indies. The fruit of many of the ebony trees is considered edible by the natives, although it is generally astringent. The famous oblivion-producing fruit of the lotus is supposed to be that of *D. lotus* of Africa. The persimmon (*D. Virginiana*, Linn.) of the middle and southern United States is a representative of this genus. The imports of manufactured and unmanufactured ebony into the United States in the year ending June 30, 1858, were valued at $3,394.

EBRO, a river of Spain, the Iberus of the Romans, which formerly gave the name of Iberia to the fine country which it waters. It has its source in the mountains on the N. border of Spain, in the province of Santander, and pursues a S. E. course, flowing at first between lofty and picturesque heights, separating Biscay and Navarre from Old Castile, intersecting Aragon near its centre, and after a course of about 400 m. emptying into the Mediterranean through a double embouchure at Cape Tortosa, near the S. extremity of Catalonia, in lat. 40° 42′ N. At Mequinenza it passes through a defile where once was probably a barrier to its waters, restraining them as a lake in the country of Aragon. Its principal tributaries are the Aragon, Gallego, and Segre, on the left or N. side, and the Oca, Jalon, and Guadalupe, on the right or S. It abounds with shoals and rapids, but boats may pass with difficulty as high as Tudela, 180 m. from its mouth. It presents so many obstacles to navigation that a canal has been cut parallel to its bank for a long distance N. of Saragossa and S. of Amposta; and the bed of the river between these 2 points is now being elaborately improved. The principal traffic on the river is the transport of grain, and the floating of timber from the northern forests.

EBULLIOSCOPE, or Ebullition Alcoholometer, a form of thermometer used for determining the boiling point of spirituous liquors, from which the quantity of alcohol present is calculated. It is variously graduated as modified by different chemists. That of Dr. Ure is adapted to the scale of Sykes's hydrometer. For the purposes of manufacturers this instrument may be useful, but not for analysis. The boiling point of pure water and the height of the barometer should be noticed in making the observation.

EBULLITION. See Boiling Point, and Evaporation.

ECBATANA, one of the most renowned of ancient cities, the capital of the Median empire, and the favorite summer residence of the kings of Persia. Its foundation, like that of several other towns which were older than historical record, was attributed to Semiramis; and Diodorus locates it near the foot of Mt. Orontes, the modern Elwend. Herodotus assigns to it a later origin, making Deioces its founder, and describes particularly its position upon a conical hill, and its enclosure by 7 concentric walls, each inner one being higher than the next outer one, which were painted with a series of different colors, the innermost wall being gilded, and the next plated with silver. He swells the account beyond probability by saying that the outer wall equalled in circumference that of the

city of Athens. There are various discordant allusions to Ecbatana in the Bible and in several of the Greek historians, but the comparison of texts and the observations of modern travellers have rendered it probable that this city was founded and flourished subsequently to Babylon and Nineveh, and that it occupied the position ascribed to it by Diodorus and others near the site of the modern city of Hamadan. Its citadel was of enormous strength, and adjoining it was the royal palace, rivalling in elegance the noblest edifices of the East. The fragrant cedar and the cypress were the only kinds of wood that entered into its construction, and its columns, beams, and ceilings were covered with golden and silver plates. Its splendid architecture and spacious apartments, its fountains and gardens, and the mild climate of the place, attracted to it, even after the fall of the Median empire, the sovereigns of Persia, to repose during the summer months from the fatigues of war and the cares of state. Darius fled from his defeat at Arbela to Ecbatana, and Alexander the Great, having become master of the town, bore away a rich booty. Under the Seleucidæ its edifices and palaces were plundered, and its ramparts began to crumble away; yet Antiochus the Great found wealth still remaining to be pillaged. Ecbatana subsequently fell to the Parthians, and was the frequent residence of Parthian kings; but its ruin was completed amid the revolutions which preceded the establishment of the new Persian empire, and of its former magnificence there remain only a few broken columns, cuneiform inscriptions, medals, and fragments of sculpture, dug from the earth in the vicinity of Hamadan. Though most modern travellers and scholars have supposed Hamadan to occupy the site of ancient Ecbatana, Col. Rawlinson, in a learned and most elaborate paper in the "Geographical Journal" (x. 65–158), has contended for the existence of two capitals of this name, one of which he places at Hamadan, and the other in the hill country of Upper Media at Takhti-Soleiman. He accounts for the discrepancies in the ancient allusions by supposing that the two districts of Media were not properly distinguished, and has illustrated the subject by a careful study of all the authorities and localities. The Chaldean form of the name in Ezra (vi. 2), Achmetha, answers both to the name found on the Behistun inscriptions, Hagmatana, and the modern Hamadan. In the Greek, Agbatana, the *m* of the original form is changed into *b*, both letters being labial.

ECCALEOBION (Gr. εκκαλεω, to call out, and βιος, life), an apparatus for hatching eggs by artificial heat. A uniformly warm temperature, it is found, is all that is required for successful incubation, and this may as well be supplied artificially as by the hen. This fact was understood by the ancient Egyptians, who made use of stoves for this purpose; and the art is still practised by the modern Egyptians. Public attention was directed to the subject by Réaumur in France more than 100 years ago; and before the period of the French revolution the operation was successfully conducted in that country by M. Bonnemain, an account of whose apparatus is given by Dr. Ure, from his own observations, under the head of "Incubation, Artificial," in his "Dictionary of Arts." In the "American Journal of Science" (vol. ix., 1824) is an account of a similar apparatus of Mr. Barlow, near London, first published in the *Bulletin d'encouragement;* and "Chambers's Edinburgh Journal," No. 400, contains an interesting description of the same operation. The apparatus of M. Bonnemain appears to have been the first application of heated water conveyed from a boiler in iron pipes to the warming of apartments. In that of Mr. Barlow the ovens were warmed by steam pipes. Each was an arrangement of shelves one above another, upon which the eggs were placed and kept 21 days, when the chicks came forth. By introducing every day the same number of eggs, the apparatus is continued in regular operation, and with greater certainty than when eggs are hatched in the natural way. In order that the eggs may not become too dry, water is evaporated in the ovens. When the chickens emerge from the shells they are left a few hours to become dry, and are then removed to another apartment kept at a temperature of about 80°, where they are left for a day without feeding, the yolk of the egg which passed into the intestines 24 hours previous to the hatching supplying the necessary nourishment for 30 hours after it. They are then fed with millet seed or cracked grain. Care is required at night that they should be provided with warm coops lined with flannel, in which a dozen or so may comfortably nestle together as under the wing of the hen. The advantages of this method of raising chickens are, the large numbers that may be produced with comparatively little cost of attendance; the supplies thus obtained at all seasons of the year; the reduction of the loss occasioned by the frequent death of chickens left to the ordinary method of raising; and the saving effected by the hens being kept constantly laying eggs instead of spending a month or two at a time in the hatching and rearing of their broods. In some localities in Europe advantage has been taken of the heat afforded by hot springs, and eggs have thus been successfully hatched without other expense for the required warmth. Numerous localities in the United States afford opportunities for the same process.

ECCENTRIC, having different centres; in opposition to concentric, which signifies that the centres coincide. In machinery, an eccentric is a crank in which the length of the arm of the crank is very short in comparison with the diameter of the crank; so that it is conceived of as a circle, rotating round a line not passing through its centre.

ECCHELLENSIS, or Echellensis, Abraham, a learned Maronite, professor of the Syriac and Arabic languages in Paris and in Rome, born at Eckel, in Syria, died in Italy in 1664. He went

to Rome to pursue his studies, and took there the degree of doctor of theology and of philosophy. In 1630 he was invited to Paris to assist in editing the polyglot Bible of Le Jay, and for his services received 600 crowns annually. He contributed to this work the book of Ruth in Syriac and Arabic, and the 3d book of Maccabees in Arabic. In 1642 he returned to Rome, and obtained in that city a professorship of the oriental languages.

ECCLESIA, in ancient Athens, a general assembly of the citizens for the purpose of discussing and deciding matters of public interest. The ordinary assemblies were held 3 times monthly on established days; the extraordinary were specially convened on any sudden and pressing emergency. When the occasion was one of extreme importance, special messengers were despatched into the country to summon the people to attend, and the assembly thus convened was termed a cataclesia. These assemblies were originally held in the Agora; but during the most flourishing periods of Athens, in the times of Themistocles, Pericles, and Demosthenes, they were usually held upon the rock of the Pnyx, where a semi-circular space, partially formed by excavation from the native rock, and containing 12,000 square yards, could accommodate all the Athenian citizens. There were neither seats nor awning, and the assembly met at daybreak. The *bema* on which the orators stood to address the people was carved from the rock, and yet remains. It was often called "the stone;" and as the destinies of Athens were swayed by the orators who stood upon it, it became a figure of speech for the existing government, and the phrase "master of the stone" indicated the ruling statesman of the day. At a later period the assemblies were often held in the great theatre of Dionysus, and also in the Piræus, and in the theatre at Munychia. The right of convening the citizens was vested in the *prytanes*, or presidents of the council of 500, but in times of war or sudden emergency the generals also had the power to call extraordinary assemblies. Notice was given of the meeting by public proclamation, and any citizen refusing to obey the call was fined. The poorer classes received a small pecuniary fee for their attendance as a recompense for their time. Before the assembly entered upon any business, a sacrifice, usually of a suckling pig, was offered, and incense was burned. Then the herald proclaimed silence and offered a prayer to the gods; after which, under the direction of the prytanes and the *proëdri*, or heads of tribes, the subjects to be discussed were stated, and permission given to the speakers to address the people. No measure could be acted upon in the assembly which had not previously received the sanction of the senate, but the decrees of the senate might here be approved, altered, or rejected; and a new bill might be introduced upon a subject which had already been discussed in the senate. According to the older regulations, those persons who were above 50 years of age had the privilege of speaking first; but this distinction was obsolete in the days of Aristophanes, and citizens of every class and age had an equal right to speak. No new decree, however, could be publicly proposed till it had been shown to the proëdri, that they might see whether it contained any thing injurious to the state or contrary to existing laws. The people voted either by show of hands or occasionally by ballot, the latter method being by white and black pebbles. Beside the legislative powers of the assembly, it could make inquisition into the conduct of magistrates, and in turbulent and excited times exercised a power resembling that of impeachment, as in the cases of Demosthenes and Phocion. The assembly was sometimes suddenly broken up at the occurrence of an unfavorable omen, as thunder and lightning, sudden rain, or any unusual natural phenomenon.

ECCLESIASTES, or the Preacher (Heb. *Koheleth*, assembler), one of the didactic books of the Old Testament canon, professing to be the words of the preacher, the son of David, king in Jerusalem. It contains allusions to the writer's riches, palaces, and parables, and its sententious style reminds one of the author of the Proverbs. Yet its diction is marked by Chaldaisms and linguistic usages which are thought not to have been introduced into the Hebrew language till about the period of the Babylonish captivity. The authorship of the Ecclesiastes has been attributed to Solomon, whose claims have often been challenged and always defended; and if it be not his, it must remain entirely uncertain, for no writer of the Babylonian period is known so nearly resembling him in wisdom and wealth of thought. The book consists of philosophical reflections upon human life, and while it affirms: "Vanity of vanities, all is vanity," it also comes to the conclusion of the whole matter in the words: "Fear God and keep his commandments, for this is the whole duty of man." Some entertain the opinion that its original form must have been a dialogue in which the sage carries on a discussion with a sceptic and a libertine. Yet it is more commonly regarded as the monologue of a Hebrew moralizing on life and searching for the highest good, scanning the perversities and follies of man, and at length, after a review of the evidence, declaring the verdict that obedience to God is the only real and substantial good.

ECCLESIASTICUS, one of the apocryphal books of the Old Testament, called also the "Wisdom of Jesus, the Son of Sirach." The author lived in the 2d or 3d century B. C., and wrote in Hebrew, though no copy of the Hebrew original has been preserved; and his work was subsequently translated into Greek by his grandson. The book contains: 1, an anthology of moral and prudential precepts for the various circumstances of life; 2, a discourse which the author puts into the mouth of wisdom herself, inviting men to virtue; and 3, a panegyric in which the author celebrates the praises of God

and eulogizes the great men of his nation. In the Roman Catholic church it has been held as canonical since the council of Carthage, whose decision was confirmed by the council of Trent.

ECHELON (Fr., round of a ladder), in military language, the order of arrangement when separate bodies are drawn up behind each other obliquely, each to the right or left of the one preceding, so that the whole force presents the outline of a stairway.

ECHEVIN (Lat. *scabini*), a name given in France from the time of Charlemagne to the assessors in the provinces. They were royal officers, and appointed with the design of securing a uniform administration. At first they combined the administration of justice with that of finance, but in the 12th century the judicial functions were performed by other officers, and from that time the echevins were found only in cities. In Paris they were not only assessors, but had authority in matters of police relating to commercial affairs, till they were suppressed by the law of 1789, which organized new municipalities.

ECHINADES, a group of islands in the Ionian sea, off the coast of Acarnania, near the entrance of the gulf of Corinth. They lay at the mouth of the Achelous, and were said to have been formed by the alluvial deposits of that river; and Herodotus says that many of them in his time had become reunited to the mainland. According to the legend, they were nymphs who dwelt upon the mainland at the mouth of the Achelous, but having forgotten on one occasion to pay their offerings to the god of that river, the angry divinity tore them away from their residence on the land, carried them out to sea, and formed them into islands. They took their name from the *echinus*, or sea urchin, in consequence of their sharp and prickly outlines. The largest of them was Dulichium, now a part of the mainland. Homer describes them as inhabited, but later writers speak of them as barren and deserted. At the present time they are the seat of 5 small villages, but are of little importance for their extent or productions.

ECHINODERMS, ECHINODERMATA (Gr. ἐχινος, a hedgehog, and δερμα, skin), a class of invertebrate animals, so named from the spines with which many of the species are covered. It includes a number of families, both recent and fossil, among which the echinidans or sea urchins, the stelleridans or star-fish, and the crinoideans, are the most prominent. The class is distinguished among the radiata by the animals possessing the power of locomotion, and being protected by a strong external covering. Though ranked as the highest class in Cuvier's 4th division of the animal kingdom, the radiata, it has been shown by Agassiz that they do not conform to the structure upon which this great division is founded, viz.: of organs disposed like rays about a common centre, which is the mouth or axis of the body. On the contrary, they have a bilateral arrangement of organs, or a right and left side, which really belongs to the other divisions. The order *holothurida* of this class has long been regarded as a connecting link between the radiata and articulata. The echinoderms are found in all the fossiliferous formations, abounding especially in the oolitic and cretaceous. It is remarkable how little they have changed in their forms, most of the oldest fossils of this class being referred by Goldfuss in his *Petrefacten* to existing genera.

ECHINUS (Gr. ἐχινος, hedgehog), a genus of the echinoderms, the type of the class, and represented by the sea urchins or sea eggs common on our coast. They are animals inhabiting globular-shaped cases with flat bases, formed of calcareous plates accurately fitted together in rows of larger alternating with smaller plates, the former covered upon the outside with movable spines like coarse bristles. In some species they are 5 or 6 inches long, exceeding in length the diameter of the body. These spines fit by a ball and socket joint into little depressions, which occupy the centre of tubercles that cover the larger plates, and by the movement of the outer skin to which they are all attached, they admit of considerable motion. Beside these organs of motion, upon which the weight of the animal not buoyed up by the water is sustained, hundreds of tubular feet project through smaller tubercles upon the smaller plates. These being transparent are seldom noticed, but they may be thrust out beyond the spines, and having a little sucker at their ends, they serve to take hold of any object that comes in contact with them; and thus the animal may cause the shell to roll slowly, the spines aiding the motion. The tubular feet also serve to seize their prey, one foot after another fastening to it and passing it around to the mouth, which is in the centre of the under portion of the shell. This being furnished with a powerful arrangement of teeth, small shellfish and crabs are easily masticated. The echini are found of numerous species, fossil as well as recent. They first appeared in the epoch of the coal, and have since abounded in the later formations. In the greensand formation of New Jersey they are found in large quantities, beautifully preserved in the straw-colored limestone. The chalk of Great Britain is also a famous repository of them.

ECHO. Sound comes to the ear direct from the object producing it; and is returned, as light is reflected to the eye, from surfaces that intercept its progress. When the interval of time between the direct and reflected sounds is sufficient to be appreciated, a repetition of the noise is produced, which is called an echo. The same repetition of a flash of light from distant surfaces upon the earth would be perceived, were the velocity of light no greater than that of sound. The distance of the reflecting surfaces is thus an important element in the qualities of the echo. The time occupied by the passage of sound over the space of 100 feet may be appreciated, inasmuch as 10 distinct impulses upon the sense of hearing may be distinguished in a second, during which time the sound at ordinary temperatures passes 1,125 feet, or at the freezing tem-

perature 1,090 feet. Sounds reflected from the walls within ordinary buildings are confused, and do not form distinct echoes from their succeeding one another too rapidly for the ear to detect the intervals between them. But if the building be very large, distinct echoes may be produced in some parts of it, and these may be repeated several times by the wave of sound being reflected from surfaces at different distances, and consequently coming back at distinct intervals. A wave also may be reflected from one side to another, as a ball upon a billiard table, and at last, having traversed a space much greater than its extreme distance at any time, come back to the starting point. The analogy, however, is not complete in the case of concave surfaces, the waves of sound in these being concentrated, as the rays of light are concentrated in the focus of a concave mirror, and returned with increased effect. The number of distinct sounds that may be brought back depends upon the distance of the reflecting surface; the further off this is, the more time there is for a number of successive impulses to be sent forth before the first of the series can return to be confused with the direct sound of the last. If the surface be 500 feet distant, about one second is occupied by the sound in going and returning, and in this time 9 or 10 distinct sounds may be uttered. Such an echo may be a repeating one also, giving the same sounds several times over. They may come back in the same pitch, or each sound a note lower. An instance of the latter is cited by Dr. Charles G. Page in the "American Journal of Science" (vol. xxxvi., 1839). The locality is upon his father's grounds in Fairfax co., Va. Three reflections are given, the second much the most distinct, and 13 syllables may be distinguished. Twenty notes played upon a flute are returned with perfect clearness. Some notes in the scale, however, are not returned in their places, but are supplied by notes which are either thirds, fifths, or octaves, and the effects are observed to vary with the changes of the atmosphere or of the wind. Another echo is noticed in the same article, which has been observed between two barns at Belvidere, Alleghany co., N. Y. It repeats a word of 3 syllables distinctly 11 times, at whichever of the two the sound is made, becoming fainter each time. A person placed about midway between the two barns can distinguish a monosyllable as the sound traverses each way past him in quick succession to the number of 22 times. The distance apart of the two barns is not given. Back of each is a range of hills, the valley being that of the Genesee river. At the Simonetta palace near Milan an echo is spoken of in the "Philosophical Transactions" (1766), which repeats the sound of a pistol no less than 60 times. In this instance the experimenter is probably nearly midway between the two reflecting surfaces. The rolling of the thunder is in part probably a continuation of echoes returned from the clouds. The effect in the heavens may possibly be owing to the great difference of distance from the observer along the line of an instantaneous flash, the sound of the more remote portions coming to the ear after that produced nearer by. The stunning crash sometimes heard may be when one happens to stand near the focus of a circular discharge, as within the dome of a cathedral. In large buildings of this class some very curious effects are often noticed resulting from the reflection of sounds from their walls; a slight noise is multiplied into a confused roar, or it may be reflected from some surface and conveyed to a remote part of the building with all its original clearness and distinctness. Though this is not properly an echo in the usual sense of a returned sound, it is a reflection of sound sent to another point by a different route than the direct one, and may therefore be classed with echoes. Whispering galleries are of this nature. Two points within the building stand in the relation to each other of the two foci of an ellipse, the ceiling presenting the ellipsoid reflecting surface more or less perfectly; the more perfect and extended, the more distinctly is the sound produced at one of the foci concentrated at the other, even when their distance apart is so great that the direct sound may not reach half so far. Were the ceiling in this case a bright mirror, the rays from a light at one of the foci would in like manner be reflected and concentrated at the other, illuminating the surface of any object, though the faint glimmer might scarcely be perceptible in the dark intervening space. Examples of these galleries are often met with in large structures. That of St. Paul's, London, is often cited. The gallery is 140 yards in circumference, and is just below the dome. The distance across is nearly as many feet. A whisper near the wall on one side is conveyed to a person on the opposite side, as a loud voice apparently close to his ear, yet it is not heard in the intermediate space. The shutting of a door produces a sound like a peal of thunder rolling among the mountains.—To avoid the confused sounds produced by echoes in buildings designed for public speaking, and at the same time properly distribute the sound of the voice with all its distinctness, it is recommended to give to the apartment a length equal to $1\frac{1}{2}$ or $1\frac{1}{4}$ times the breadth, and a height somewhat greater than the breadth. The ceiling should be higher in the centre than at the sides, and should join these by bevelled edges. Its surface also should be broken into compartments and roughened by pendants.

ECHO, in Greek mythology, an oread nymph, daughter of the earth and air. She dwelt upon the banks of the Cephissus, not far from Athens, at the foot of Mt. Pentelicus, and became so desparately in love with Narcissus, son of the river, that she followed him through the forests, in the chase, to the darkness of grottoes, and to the borders of fountains, and ever repeated in solitary places the name of her beloved. Narcissus disdained her passion; and she retreated into the depth of the woods, and concealed her-

self. There she pined away in secret, and no longer appeared among the choirs of nymphs. Only her plaintive voice was always heard in the distance, which occasioned the saying that her bones were changed into rocks, and her voice alone remained.

ECIJA (anc. *Astigis*), a city of Andalusia, Spain, on the Genil, 42 m. E. N. E. of Seville; pop. 23,722. Its industry consists chiefly in the manufacture of woollens, leather, shoes, and saddlery. Some have supposed that Ecija was visited by the apostle Paul. It was the rival of Cordova and Seville, and for a long time a border town between the Moors and Christians, and the scene of many romantic adventures. Many inscriptions and relics of antiquity still exist here.

ECK, or ECKIUS, JOHANN MAYR VON, a German theologian, distinguished by his opposition to Luther, born in Eck, in Swabia, Nov. 13, 1486, died in Ingolstadt in 1543. The son of a peasant, he acquired, by a profound study of the Christian fathers and the scholastic philosophers, an erudition and skill in disputation which Luther and Melanchthon much admired. He was doctor of theology, canon of Eichstädt, and vice-chancellor of the university of Ingolstadt, when in 1518 he appeared as an adversary of Luther by his notes upon the theses of that reformer. He subsequently met Luther and Carlstadt in the conferences at Augsburg and Leipsic, but failing to convince them by his arguments, he repaired to Rome to urge more severe measures against them. He returned to Germany with a papal bull of condemnation, but at Leipsic the people had so warmly embraced the new doctrines, that he saved himself from violence only by retreating to a convent. He subsequently labored fruitlessly to reunite the divided church.

ECKERMANN, JOHANN PETER, a German literary man, born in Winsen, Hanover, in 1792, died in Weimar, Dec. 3, 1854. He is chiefly celebrated for his intercourse with Goethe, to whom he became first known by a volume of poetry which he published in 1821. He assisted Goethe in his last edition of his complete works, and was named in his will editor of his literary remains, which were accordingly published in 1832–'3. In 1839–'40 he edited a complete issue of Goethe's works in 40 volumes; but the work which won for him much reputation was his publication of his conversations with Goethe, or *Gespräche mit Goethe* (3d and last volume, Magdeburg, 1848). Extracts of this work were translated into many foreign languages, including the Turkish. The first English translation was made by Margaret Fuller, and published at Boston, Mass., in 1839. Another English translation by Oxenford appeared at London in 1850. Eckermann accompanied Goethe's son to Italy in 1830; and on his return to Weimar he was appointed teacher of the hereditary grand duke. In 1836 he became director of the library of the grand duchess of Weimar. Of Eckermann's original poetical productions, those published at Stuttgart in 1823 derive interest from their allusions to Goethe.

ECKFORD, HENRY, an American ship-builder, born in Irvine, Scotland, March 12, 1775, died in Constantinople, Nov. 12, 1832. At the age of 16 he was sent to Canada and placed under the care of his maternal uncle, Mr. John Black, a naval constructor of Quebec. In 1796 he removed to New York, where his skill in modelling and constructing vessels soon gave him ample employment. He was in the habit of obtaining from the commander of each of his ships an accurate account of her properties under all the casualties of navigation, and with the experience thus gained he endeavored to improve step by step upon each succeeding model. Many important changes in the hull and rigging of vessels date from the commencement of his labors in New York, and the supremacy of that city in naval architecture became generally recognized throughout the United States. During the war of 1812 he entered into a contract with the U. S. government to construct vessels of war on the lakes, and soon had an excellent fleet afloat and equipped, notwithstanding that it was necessary to fell the timber in the neighboring forests, and to transport the rigging, sails, and other materials from the seaboard. Shortly after the war he constructed the steamer Robert Fulton, which in 1822 made the first successful voyage by steam to New Orleans and Havana. She was subsequently altered into a sailing vessel, and became the fastest sloop of war in the Brazilian navy. In 1820 he accepted the appointment of naval constructor at the navy yard in Brooklyn, where the line-of-battle ship Ohio was built from his designs. On the day that she was launched, however, he resigned his commission, in consequence of disagreements with the officers composing the bureau of construction. He subsequently constructed vessels of war for various European powers, and for some of the South American republics. Upon the accession of Gen. Jackson to the presidency he was invited to furnish a plan for a new organization of the navy, and the suggestions which he offered, though not adopted, were considered judicious and practical. About this time he projected a work on naval architecture and the establishment of a professorship on that branch of science in Columbia college. In 1831 he built a sloop of war for Sultan Mahmoud, and received from that sovereign an invitation to enter his service as naval constructor. He accordingly took up his residence in Constantinople, where he organized a navy yard, and laid the keel of a ship of the line, which, however, he did not live to see completed.

ECKMÜHL, a village of Bavaria, on the river Great Laber, in the circle of Lower Bavaria, 13 m. from Ratisbon, memorable for the great victory gained here by Napoleon over the Austrians under the archduke Charles, April 22, 1809. Marshal Davoust, having especially signalized his valor during the engagement, was created

prince of Eckmühl. This battle, and the partial actions which had preceded it, cost Austria 25,000 men, and obliged the archduke Charles to retire into Bohemia, and to leave open to Napoleon the highway to Vienna.

ECKSTEIN, Ferdinand, baron d', a French publicist, born of Jewish parents in Denmark in 1790, became a convert to Lutheranism in 1807, and afterward to Catholicism. He studied in Göttingen and Heidelberg, took a part in the campaigns of 1812–'14, held various offices under the government of the Netherlands and of the Bourbons in France, who conferred on him the title of baron, and retired from public life in 1830. From 1826 to 1829 he conducted a periodical, *Le Catholique*, in which he advocated the religious views of De Maistre and De Bonald. He has since written for the *Avenir*, the Augsburg *Allgemeine Zeitung*, and various scientific periodicals, and enjoys a high reputation for his familiarity with the literature of Hindostan.

ECLECTICS (Gr. εκλεγω, to select), a class of ancient philosophers who professed to select whatever was good and true from all the other philosophical sects, that they might combine it in a new system. They held Plato in the highest esteem, but did not hesitate to add to his doctrines whatever they thought conformable to reason in the tenets of the other schools, or to reject from his teachings whatever they disapproved. The eclectic system is supposed to have originated with Potamon of Alexandria, a Platonist; it was in a flourishing state at Alexandria about the beginning of our era; and it reached its perfection under Ammonius Saccas, who blended Christianity with his views, and founded the sect of the Ammonians, or New Platonists, in the 2d century. The moral doctrine of the Alexandrian school was, that the mind of man, originally part of the Divine Being, having fallen into darkness and defilement through its connection with the body, is to be gradually emancipated from the influence of matter, and rise by contemplation to the knowledge and likeness of God; and that this result, which is the great end of philosophy, is to be attained through abstinence, voluntary mortification, and religious exercises. In the infancy of this school, not a few professors of Christianity were led, by the pretensions of the eclectic sect, to think that a coalition might advantageously be formed between its system and that of the gospel; and this union seemed the more desirable when several prominent eclectics became converts to the Christian faith. The only consequence, however, was the corruption of the pure and simple doctrines of the New Testament, by their mixture with pagan ideas and opinions.—The term Eclecticism is also used by Victor Cousin to represent his own philosophical system. (See Cousin, Victor.)

ECLIPSE (Gr. εκλειψις, failure), the interception of light from one heavenly body by the intervention of another. An eclipse of the moon is the passage of the moon into the shadow of the earth. It is evident that this can only happen at full moon, and then only when the moon is nearly in the plane of the ecliptic, *i. e.* in the plane of the earth's orbit. These eclipses occur often, and are beautiful phenomena; but the edge of the shadow of the earth is not defined with sufficient sharpness to make lunar eclipses of much value to the progress of astronomy. Solar eclipses are caused by the earth's passing into the shadow of the moon, and of course occur only at new moon, and when the moon is nearly in the plane of the ecliptic. As the moon is much smaller than the sun, its shadow runs rapidly to a point, and never covers more than a small portion of the earth; hence the phenomenon of a total eclipse is very rarely seen. But as the cone of the moon's shadow is surrounded by a larger inverted cone of penumbra, *i. e.* of space in which the moon intercepts a part of the light, the opportunities of seeing a partial eclipse of the sun are much more frequent. The instant of entering the penumbra is sharply defined by an apparent indentation in the limb of the sun, and that of entering the shadow by the total disappearance of the sun. It sometimes happens that the moon is too far from the earth to allow her shadow to reach us, in which case persons in the centre of the penumbra see a ring of the sun surrounding the moon; this is called an annular eclipse (Lat. *annulus*, a ring). It is evident that solar eclipses afford the means of testing our calculations of the moon's motions, and of determining the longitude of places on the earth. The beginning and ending of the partial, of the total, and of the annular phases, and the distance apart of the ends of the indentation in the sun's limb, all may be calculated and observed with great accuracy, and the observations are of great use in correcting the assumed data of the calculation of the moon's motions, and the longitude of the places of observation. Total eclipses also afford opportunities for many interesting observations on physical phenomena, and on the emotions of the animal tribes; the most singular optical effect being the occasional issuing of rose-colored flames from the sun during the total phase. Eclipses of the sun by Venus and Mercury are called transits; they occasion an inappreciable diminution of light, are rare occurrences, and are of much astronomical utility. Eclipses of stars and planets by the moon are called occultations, and possess a value similar to that of solar eclipses. The eclipses in Jupiter's system are of 4 kinds: the satellites pass into the shadow of Jupiter, or may cast their shadow upon his face; they may pass between us and their primary, or may pass behind him. The last named eclipses were at one time the most important means of determining longitude at sea, as the eclipse gave the Greenwich time for direct comparison with the time at the ship. Solar eclipses and occultations, being of great use in determining longitudes, are calculated beforehand so accurately as to prepare the observer to be on the watch at the right

moment, which can be ascertained by means of an instrument invented by Thomas Hill of Waltham, Mass., which marks out on a chart of the sky the moon's apparent motions as seen from any part of the earth's surface.

ECLIPTIC (from eclipse, being the region of lunar and solar eclipses), the great circle in the heavens, in the circumference of which the sun appears to move during the annual revolution of the earth. This great circle makes an angle of about 23° 28′ with the equinoctial or celestial equator (the great circle equidistant from the poles), which is called the obliquity of the ecliptic, and is evidently equivalent to the angle which the axis of the earth makes with a line perpendicular to the plane of its orbit. The points where the equator cuts the ecliptic are called equinoxes, because when the sun is there the days and nights are equal in all parts of the globe. The ecliptic is divided into 12 equal parts called signs: Aries ♈, Taurus ♉, Gemini ♊, Cancer ♋, Leo ♌, Virgo ♍, Libra ♎, Scorpio ♏, Sagittarius ♐, Capricornus ♑, Aquarius ♒, Pisces ♓. These signs formerly coincided with the constellations of the same names, which now occupy places about one sign to the east, so that the constellation Aries is in the sign Taurus, &c. The first point of ♈ is the vernal equinox, or point at which the sun ascends about March 20 to the northern side of the equator; the autumnal equinox is the first point of ♎, where the sun descends south of the equator. The point at which the sun is furthest north, about June 20, is the summer solstice or solstitial point; this is the first point of ♋; while the winter solstice is the first point of ♑, reached by the sun about Dec. 20. The obliquity of the ecliptic suffers a diminution of about 48″ in a century, but the limits of this diminution are said to be fixed. The equinoxes also move on the ecliptic in the direction opposite to the sun's apparent motion, at the rate of about 50.22″ a year, which is called the precession of the equinoxes. The obliquity of the ecliptic also suffers a monthly annual variation, called nutation, arising from the action of the sun and moon upon the protuberant regions of the earth's equator, which makes the direction of the earth's axis slightly oscillatory. The effect of nutation is to cause the pole of the heavens to move in a minute oval about its mean position. That the obliquity of the ecliptic has not materially changed since the creation is shown by the fact in geography first pointed out by Peirce, that the principal coast lines and mountain chains either coincide with, or are perpendicular to, the line separating light and darkness when the sun is at the solstices. The whole of the present faunas and floras of the world are also adapted in their constitution to the present obliquity of the ecliptic and average course of the seasons. For it is evident that a perceptible change in the obliquity of the ecliptic would produce a change in the average temperatures of summer and winter, which would drive plants further north or further south according to their ability to endure sun and frost.

ECLOGUE, a pastoral poem. The names eclogue and idyl, both of Greek derivation, are given indifferently to short poems commemorating the events of rural life. The distinction which has been made, that idyl belongs to pieces in which the poet himself relates the event, and eclogue to pieces in which he conceals himself and introduces shepherds as actors, is not strictly observed.

ECUADOR, or Equador, a republic of South America, lying between lat. 1° 35′ N. and 5° 50′ S., and between long. 68° 20′ and 81° 12′ W. Its name is derived from its position under the equator. It is bounded N. by New Granada; E. by New Granada, Brazil, and Peru; S. by Peru; W. by the Pacific. The boundary lines between Ecuador and New Granada, Brazil, and Peru have never been definitely settled, the Ecuadorians claiming territory extending S. of the Amazon or Marañon, over which Peru asserts jurisdiction, and a tract lying between the Putumayo river and the cordillera of Caqueta, which is also claimed by New Granada. As however the territory thus disputed is as yet only inhabited by Indian tribes, its present value is comparatively small. The area of a country whose boundaries are so unsettled cannot be definitely ascertained. It is probaby not far from 250,000 sq. m.—The Pacific coast has many indentations, few of which, however, form good harbors. The principal gulfs are those of Guayaquil, at the mouth of the Guayaquil river, and that of Ancon de Sardinas, between the rivers Mira and Santiago. There are also 3 considerable bays, that of Caracas, S. of Cape Pasado; that of Mompiche, S. of Cape San Francisco; and that of Pailon, which is rather what the Scotch call a frith than a proper bay. The principal harbors are Guayaquil and Manta. The bays and gulfs are studded with a considerable number of islets, a few of them inhabited, and all adding by their rich tropical vegetation to the beauty of the scenery.—Ecuador is decidedly a mountainous country; the Andes extend over the greatest part of its territory, spreading out in elevated plateaus called *paramos* by the inhabitants, and rising in lofty peaks from these elevated plains. There are 3 principal cordilleras, or ranges of mountains, into which the Andes are divided, as they enter Ecuador from the north: the easternmost, which retains the name of Andes, and which as a whole maintains the greatest elevation; the western cordillera, or range, connected with the first by a broad plateau, having an elevation of from 10,000 to 16,000 feet above the level of the sea, and from either border of which shoot up the lofty peaks which stand like sentinels along the elevated plain; and, still nearer to the coast, a lower range extending in lines parallel or nearly so to the Pacific shore, beginning near the New Granadian line, in a knot or group of mountains which unites the 3 ranges, and losing itself in the salt marshes near the mouth of the Esmeraldas. The inhabitants of

the mountainous districts have given the name of knot (*nudo*), or group, and also of *paramo* (cold, bleak desert), to these elevated plateaus, many of which, though maintaining nearly the same mean elevation, are any thing but level. Of these there are 8 principal ones, beside many of less note. They are, beginning at the north, the *nudos* of Huaca, Cajas, Tiopullo, Pomachaca, Assuay, Portete, Acayana, and Savanilla. The general direction of the great mountain chains is S. S. W., but from each side of these spread out spurs and ramifications, which render most of the territory of the republic a labyrinth of mountains. Twenty-two of the mountains of Ecuador rise above the limit of perpetual snow, and 25 more rise above 10,000 feet. Of these a majority are volcanoes, some constantly active, others occasionally so; some pouring out lava and scoriæ, others vomiting upon the valleys below rivers of hot and sulphurous waters, or masses of semi-liquid mud. The following table is given by Villavicencio of the names and height of those which rise above the snow line, from the very latest measurements, which, as will be seen, differ slightly from the generally received figures:

Eastern range.	Feet.	Western range.	Feet.
Cayambi	19,813	Chimborazo	21,371
Antisana	19,301	Ilinisa	17,649
Cotopaxi	19,162	Casalagua	16,864
Llanganate	18,639	Cotacachi	16,650
Altar	17,626	Pichincha	16,213
Sincholagua	17,473	Corazon	16,169
Sangai	17,284	Atacasho	16,169
Sara-urcu	17,276	Chiles	15,952
Tunguragua	16,514	Carahuirazo	15,916
Collanes (range)	17,281	Yana-urco	15,913
Assuay	15,749	Quilindaña	15,913

—The rivers of Ecuador are of two classes: those which discharge their waters into the Pacific, and have a short and precipitous course; and those which, rising in the Andes, descend their eastern slope, and unite with the Amazon or some of its large branches, forming a part of the great fluvial system of the Amazonian basin. Many of these are navigable for a considerable distance within the republic. The principal rivers discharging into the Pacific are the Mira, the Onzota or Ostiones, the Esmeraldas, the Daule, the Baba, the Yaron, the Salado, and the Tumbez, which forms a small part of the southern boundary. Of these, the Esmeraldas is the most considerable. This river rises in the vicinity of Cotopaxi, near the sources of the Napo and the Pastaza, and, after a long but circuitous course, discharges its waters into the Pacific. The lower third of the river is navigable. The Mira, the Daule, and the Tumbez are all rivers of considerable importance. The Amazon, or Marañon, forms a large part of the S. boundary, or adopting the Ecuadorian location of the Peruvian frontier, traverses the S. region of the republic, from which its principal affluents are the Putumayo, the Loreto, the Ambyacu, the Napo, the Pequena, the Chambira, the Pastaza, the Morona, and the Santiago or Paute. The Putumayo forms the N. E. boundary of the republic, unless we include the district of Mainas as belonging to it. It is one of the most important affluents of the upper Amazon, and is navigable for the greater part of its length. The Napo is the largest river wholly within the territory of the republic. It rises on the eastern slope of Cotopaxi, and has a length of a little more than 800 m., and a breadth where it joins the Amazon of 3,300 feet. It is navigable for steamboats about 550 m. The Pequena, or Tigre, is about 400 m. in length, and is navigable for 230 m. The Pastaza, like the Napo and the Esmeraldas, rises on the slopes of Cotopaxi. It is about 700 m. in length, and is navigable for 350 m. by steamboats, and 80 more for smaller vessels. The Morona is a smaller river, but is navigable for a considerable distance from its junction with the Amazon. The Santiago, or Paute, has its source in the lake of Quinuas, in the western branch of the Andes, in the province of Cuenca. Its length is about 660 m., of which about 400 is navigable for steamboats and 120 more for smaller vessels.—The climate of Ecuador varies with the elevation of the surface. Although lying directly under the equator, many portions of it enjoy a mild and delightful temperature, a perpetual spring or autumn. The sea-coast is low, hot, and sickly, but as we proceed toward the interior, we find the valleys lying between the spurs or ranges of mountains possessing a warm but not hot climate, and producing abundantly all the fruits of tropical and many of those of temperate regions; the *mesetas* or *paramos*, the elevated plains and table-lands connecting the cordilleras, are cooler in proportion to their elevation, some of them, at the height of 9,000 or 10,000 feet, like the valley of Quito, enjoying the most equable temperature perhaps on the globe, and producing fruits and flowers of all climes. The mean temperature of these plains varies from 56° to 62° F. Others, again, with an elevation of 12,000 or 14,000 feet, are cold and dreary; the surface, too barren and frigid for the growth of trees, is covered with a species of heath, and has a mean temperature of 38° to 40° F. The *mesas*, or high plains on the slopes of the elevated peaks, are intensely cold, and many of them covered most of the year with snow. There are but two seasons in the Ecuadorian climate: the winter, or rainy season, commences in December, and ends in May; the other, called summer, or the windy season, begins in June and terminates in November. The former is a season not of perpetual rain, but of frequent fertilizing showers. The period of the winter solstice is usually one of clear skies and delightful temperature, and is known as the "little summer." During the summer, rain seldom falls, but high winds prevail; at the period of the autumnal equinox there is usually some rain, and this is called by the inhabitants the "little winter." On the coast the seasons are nearly reversed; during the months from June to November the sky is very generally overcast, and a drizzling rain or mist very prevalent, while from December to May the skies are usually clear. In the vast forests which line the banks

of the Amazon and its tributaries, the rainy season is prolonged, owing probably to the influence of the forests in producing precipitation of the clouds from the summits of the Andes, which would otherwise pass over and water the more arid plains beyond.—In the article Andes the general geological structure of that mighty chain is fully discussed; we need only say in regard to the special geology of Ecuador, that the volcanoes, and indeed almost the entire mountain chains, are granite, a few of them, however, giving evidence of alluvial or diluvial deposits subsequent to their upheaval. The coasts, unlike those further south, are generally sloping, and give evidence of being the result of the more recent deposit of the detritus of the Andes. The minerals found in the Andes, either in their native state or in some of their combinations as ores, are gold, silver, iron, mercury, lead, tin, zinc, copper, antimony, manganese, sulphur, and salt. All of these are in sufficient quantities to be profitably mined. The precious metals are mostly found in the departments of Quito and Assuay, though some gold is washed from the sands of the rivers in Guayaquil. The province of Oriente is said to be particularly rich in gold and silver, but it is mostly inhabited by Indians, who habitually conceal from Europeans or other foreigners any mines or placers of which they may be cognizant. The mines of Ecuador, from a variety of causes, have not been profitably worked of late years; but under a more permanent and settled government, there is reason to hope that their great wealth may be developed. The republic does not seem to be rich in precious stones. Rubies are found, and very beautiful rock crystals. At the time of its discovery, emeralds were very abundant among the inhabitants, and were said to be obtained in the river Esmeraldas, which was thus named in consequence; but recent research renders it somewhat doubtful whether they were ever found there in very great numbers. The other principal mineral products of the republic are marble of very superior quality, alabaster, choice flints, and asphaltum.—The carnivora of Ecuador are the jaguar, the ounce, the panther, the puma, the tiger cat, and the wolf. The other wild quadrupeds are the tapir, several species of wild boar, the deer, hare, rabbit, squirrel (several species), armadillo, guanaco, vicuña, the ant-eater, one or two species of antelope, and monkeys in infinite variety, from the great Brazilian monkey down to the little *chichico* which will hide itself in your hand. The horse and ox in this, as in other South American states, roam the plains in a wild state. The cattle of the country are generally black. The domestic animals are the horse, cow, llama, ass, mule, dog, cat, &c. On the affluents of the Amazon appear the sea cow, porpoise, and dolphin. The reptiles are the large white lizard, the cayman or alligator, a great variety of small lizards, the great boa constrictor, the rattlesnake, coral snake, horse snake, striped, tiger-spotted, and other snakes, &c.; tortoises large and small, and, on the Galapagos islands, the great marine turtle, often weighing several hundred pounds. Ecuador is the paradise of birds. Many of them are remarkable for the brilliancy of their plumage; among these are the cock of the rocks, the peacock tribe, the wild turkey, and above all a great variety of humming birds, whose plumage has all the brilliancy and hues of a collection of precious gems. Others again make the woods vocal with their songs; among these are many species peculiar to the Andes, such as the lord of the woods, the cacique, the corregidor, and a great variety of thrushes, song sparrows, &c. Others, like the condor, the pelican, gull, kingfisher, heron, &c., are birds of prey. The parrot, paroquet, and macaw tribes are very abundant, and the forests are peopled with doves, pheasants, pigeons, grouse, &c.; and the rivers and marshes at certain seasons of the year furnish abundant food to the wild geese, ducks, teal, widgeons, snipes, and other wading and swimming birds. The eastern and western rivers have in their season an abundance of shad, bream, skate, barbel, blindfish, crawfish, eels, lampreys, &c. On the coast, lobsters, crabs, shrimps, oysters, clams, and mussels are found in great quantities. Insects are extremely numerous, and some of them very annoying; the mosquito, ant, spider, scorpion, and centipede are the pests of the lowlands. The coleoptera are remarkable for their size and the metallic splendor of their wing cases. The Hercules beetle is the most magnificent of his tribe, and the giant cantharides glitters in jewelled splendor; the firefly is not solely indebted to his phosphorescent powers for his beauty; and many other of the insect tribes shine in green and gold. The butterflies, like those of Brazil, exhibit on their wings almost every possible variety of form and color. Among the other insects, the cochinilla, which produces the cochineal of commerce, abounds in the valleys. On the coast are found the shellfish which produces the Tyrian purple, coral of great beauty, sponge, the pearl oyster, and snails of remarkable size.—The country is capable of producing the fruits, flowers, and shrubs of every region, from the torrid to the frozen zone. The lowlands along the coast yield in profusion tropical fruits and vegetation; as we rise higher, we find the products of more temperate climes; at the height of 9,000 or 10,000 feet we enter a grain district, which continues for the more hardy grains up to the height of nearly 13,000 feet. Above this the flora and grasses are decidedly Alpine in their character; and when we reach the lofty plains, where only occasional patches are free from the eternal snows, there is nothing but a few mosses and heaths to show that vegetable life is not wholly extinct. Medical science finds in these mountain slopes many of its choicest remedies. Here grow in abundance the cinchona tree, which yields the Peruvian bark and the quinine of commerce, sarsaparilla, ipecacuanha, balsam of tolu, vanilla, canella, copaiba, gentian, valerian, the purging cassia (*cassia fistula*), the croton tig-

lium, which produces the croton oil of commerce, solanum dulcamara, ratania, whose root is the rhatany of the druggists, matico, the palo santo, from which exudes the guaiacum of the shops, the samus cassia, the liquidambar, which furnishes the storax or liquid amber of the shops, the bitter cucumber, the poppy, the guaco, a remedy used with success by the Indians for the bite of the rattlesnake, &c. These are nearly all established articles in the European and American materia medica, recognized as constituents of their pharmacopœias; but there are very many others, highly esteemed in the domestic and medical practice of the republic, which are not known abroad. Among the nutritive plants are the cacao, which produces the chocolate, cocoa, and broma of commerce; coffee, the plantain or banana, yucca, maize, potatoes, rice, sugar cane, the sugar pear, sweet potatoes, barley, wheat, chick peas, beans, vetches, oats, rye, and other cereals; cabbages, cauliflowers, radishes, beets, artichokes, capers, asparagus, &c. Among the fruits, the most common are the pine-apple, the peach, chirimoya, granadilla, orange, mango, medlar, mazuey, sapota, lucma, paso, custard apple, guava, cucumber, papaw, watermelon, strawberry myrtle, mulberry, plum, pumpkin, anacardium or gum tree, mountain apple, and a host of others whose fame is known only in their native region. Ecuador also abounds in fibrous plants; some 12 or 15 are well known, which are adapted to the manufacture of hats, cordage, cloth, paper, &c. There are also some 20 or more woods and plants which furnish dyestuffs. But it is in forest trees, suitable for ship-building, for cabinet work, and for ornament, that Ecuador, like Brazil, surpasses most other countries of the world. Of the trees suitable for ship timber, and superior in this respect to any except the live oak of Florida and the teak of India, there are nearly 20 species; of those which are adapted for the finest and most ornamental cabinet work, nearly as many more; while of trees which are admired on account of their beauty of form or elegance of foliage, there are not less than 40 species. The gums and gum resins which enter so largely into commerce also abound here; several species of the trees which yield the caoutchouc of commerce are natives of Ecuador, as are also the trees producing the shellac and copal gums, eucalyptus, dragon's blood, gamboge, gum lac, and many others. With a much larger proportion of arable land than most countries possess, a soil of great fertility, and a climate which admits the cultivation of almost every thing which can be grown anywhere, agriculture is at a very low ebb in Ecuador. This is attributable, probably, to several causes: the unsettled state of the country, the difficulty of transportation, the want of education and intelligence on the part of the farmer, and the love of ease, induced by the mild and equable climate, and by the certainty that very slight exertion will provide the means of sustaining life comfortably. The implements of agriculture are rude and imperfect, and the idea of rotation of crops, of fertilization by manures, or of any thing like intelligent farming, hardly ever finds its way into the mind of the Ecuadorian farmer. The cereals are not raised in sufficient quantity to admit of their export. Cacao is largely exported, and much is also consumed at home. Tobacco is an important crop, and many of the agriculturists employ a part of the term of their labors in collecting the roots, gums, leaves, &c., of the medicinal and useful plants of the forest for exportation.—Manufactures are confined mainly to the simplest and most inartistic processes. The braiding of the sombreros or Guayaquil hats, from the toquilla, mocora, and other straws and grasses of the country, is perhaps the most important of the manufactures. The making of hammocks from the fibres of the agave and other filamentous plants, of sugar from the cane, of coarse clothes of cotton and vicuña wool, and of the ruder sort of ornaments of gold and silver, and the preparation of some of the fruits for a foreign market, are almost the only other branches of manufacture.—The commerce of Ecuador is of two kinds, viz.: that with New Granada and Peru, which is carried on by land, and mostly by *arrieros* or carriers, who transport the articles on their own shoulders and on the backs of mules; and the foreign commerce, which is transacted mostly by the ships of foreign nations, as the republic has very little shipping. The exports consist principally of silver and silver ore, cacao, sombreros, generally known as Panama or Guayaquil hats, lumber, tobacco, cascarilla, sarsaparilla, agave fibre, tamarinds, caoutchouc, canes, coffee, hammocks, &c. In 1856 the foreign exports by the ports of Guayaquil and Manta were $2,333,141 50, of which $67,562 12 was silver and silver ores. The exports to New Granada, across the frontier, were estimated at $300,000, and to Peru $100,000, making the entire exports $2,733,141 50. The same year the imports were, through the port of Guayaquil, $2,374,439 38; through Manta, $112,267 39; from New Granada (estimated) $40,000, and from Peru (estimated) $100,000; making a total importation of $2,626,706 77. It is doubtful, however, whether much reliance can be placed on the statistics of the border commerce. The trade of Ecuador with the United States has always been small. In 1856 she exported to the United States goods to the amount of $84,804, and imported from this country only $2,066. In 1857 her exports were $15,803, and imports $2,630.—The revenue of the republic in 1856 was $1,372,800, and the expenditure $1,358,498. The debt of the state is divided into 3 classes. The foreign debt, being 21½ per cent. of the debt incurred by the Colombian government, and at its dissolution divided *pro rata* among the states which composed it, amounts to $8,828,160, for which bonds have been issued by the Ecuadorian government; the arrears of interest are consolidated in other bonds, amounting to about $4,800,000. The

Colombian debt amounts to $2,644,368, a part of which is consolidated in 3 per cent. and the remainder in 5 per cent. bonds. The home debt amounts to $4,293,314. The revenues of the state do not afford the means of paying promptly the interest on this heavy debt, and the credit of the republic abroad is not high; nor have the frequent revolutions and civil wars enhanced it.—The actual population of the republic is uncertain. Dr. Villavicencio, taking the census of 1826 as a basis, and assuming that the percentage of excess of births over deaths will be about equal one year with another, makes the population, exclusive of the Indians of Oriente, 1,108,082, and estimates those Indians at 200,000. Other recent writers, on the contrary, estimate the entire population as under 500,000. This is probably an under-estimate, as the first is as certainly an over-estimate. Lastania, the Chilian geographer, in 1851 gave 700,000 as the population, including the district of Mainas, but excluding the Indians of Oriente. Perhaps the estimate given in Colton's "Atlas of the World" is as near the truth as any. This supposes the population, exclusive of the Indians of Oriente, to be 665,000; and allowing for these Indians 135,000, we have a total population of 800,000 in the republic. The following table gives the distribution of this population, together with the chief towns and their population:

Provinces.	Pop. (estimat'd).	Chief towns.	Pop.
Department of Quito:			
Pichincha	92,458	Quito	80,000
Imbabura	78,297	Ibarra	18,000
Leon	133,195	Tacunga	16,000
Chimborazo	118,283	Riobamba	16,000
Esmeraldas	5,513	Esmeraldas	500
Oriente	11,631	Santa Rosa	300
Department of Assuay:			
Cuenca	102,790	Cuenca	25,000
Loja	43,296	Loja	10,000
Department of Guayas:			
Guayaquil	55,627	Guayaquil	22,000
Manabi	23,910	Puerto Viejo.. Manta	uncert'n
Total	665,000		
Add for the Indians of Oriente	135,000		

The inhabitants may be classified according to races as follows:

Whites, descended from Europeans	351,672
Indians, descended from the dominant race at the time of the conquest (Quichuas)	274,440
Indians of the Oriente, estimated	135,000
Negroes	7,831
Mixed races (mulattoes, zamboes, and mestizoes)	31,057
Total	800,000

The Quichua or Quitu Indians are the descendants of the ancient inhabitants of the country, and have made considerable progress in civilization. They are mostly agriculturists, and many of them possess a good degree of skill in the simpler mechanic arts. Most of the pottery and the coarser woollen and cotton goods used in the republic are manufactured by them. The Indians of Oriente are of various tribes, wild, warlike, and impatient of restraint, and have never yet given much attention to agriculture or manufactures.—Roman Catholicism is the established religion of the republic, and the open profession of no other is tolerated; but foreigners are not molested on account of their opinions, though they would not be allowed to establish churches of other faiths, even for their own families. The whites, negroes, and mixed races are generally particular in their attention to the externals of religion; but the Indians, while usually professing a nominal Christianity, are really heathens in their belief and worship. Fetichism, the belief in the good and bad principles or powers, and transmigration of souls, are matters of universal faith and practice among them. The clergy and religious orders, as in most Roman Catholic countries, are numerous. Quito is the seat of an archbishop, and 2 bishops reside at Cuenca and Guayaquil. Of the regular clergy there are 415, of the secular 524, and of the religious sisterhoods 391.—The condition of education is very low. Taking the average of the whole state, there is 1 person in school or college for every 60 inhabitants. About $\frac{1}{10}$ of the whole number, however, are in the colleges, and in one province, that of Oriente, there are no schools. In 1856, according to the report of the minister of public instruction, there were 1 university, 10 colleges and seminaries, and 1 female college, having altogether 1,299 pupils; 260 primary schools for boys, with 9,249 pupils, and 30 for girls, with 2,783 pupils; and 8 special schools of drawing, music, &c., with 80 pupils; total pupils in all schools, 13,411.—The government of Ecuador is republican. Its present constitution was adopted in 1845, and modified by the national assembly of 1852, and by the legislature of 1853. The legislature consists of a senate of 18 members, 6 for each department, and a house of representatives consisting of 30 deputies, 10 for each department. The executive power is vested in the president and vice-president, both of whom are elected by a plurality of votes in the college of electors, which consists of 900 members, 300 from each department. They are elected for a term of 4 years, and are not eligible to reëlection until they have passed one term without office. The salary of the president is $12,000, and of the vice-president $4,000. In case of the death of the president and vice-president during their term of office, the executive power is vested in the last president of the senate, or of the house of representatives. The power of the president is limited by the constitution, in the following particulars: he may not deprive any Ecuadorian of his liberty, nor impose punishment, nor expel a citizen from the territory, nor delay the course of judicial proceedings, nor constrain the freedom of judgment, impede the elections, dissolve congress either directly or indirectly, suspend its sessions, exert his executive power at a greater distance than 30 miles from the capital, nor admit foreigners to high rank in the army, without the previous consent of congress. He has the power of selecting his cabinet, which consists of 3 ministers, viz.: of the interior, of

foreign relations, and of finances, war, and marine; and these, with a judge of the supreme court or the court of appeals, an ecclesiastic of high rank, and the vice-president, constitute the government council. The judiciary consists of a supreme court with 5 judges, elected by congress; 3 superior courts with 3 judges each, appointed by the president; inferior courts for civil suits in each province, and alcaldes or municipal judges in each canton. Slavery is not permitted in the republic, nor are orders of nobility or hereditary titles allowed. Confiscation of property is not permitted, nor can any penalty be inflicted on the family or friends of a culprit. The inviolability of life is guaranteed, even to political offenders; and trial by jury is acknowledged as the right of every offender. The chief towns are Quito, the capital, Guayaquil, the principal seaport (the ancient Tumbez), Cuenca, Riobamba, Tacunga, and Loja.—The early history of Ecuador is involved in some obscurity; from the Indian traditions it would appear that several centuries before the Spanish conquest it was a powerful kingdom, embracing about 50 provinces, and probably of greater extent than at present. The inhabitants were called Quitus or Quichus, and the kingdom Quito. About the 10th century a foreign nation, who had inhabited the sea-coast, ascended the river Esmeraldas, and subdued the Quitus. These people were called Cara, and their kings Carau shyri, or lords of Cara. For nearly 500 years these shyri ruled the kingdom with great ability, adding to their dominions, now by conquest, and now by matrimonial alliances with neighboring chiefs. Their kingdom at length became so powerful as to excite the cupidity of the incas of Peru, who, lords of the most powerful empire of South America, aspired to govern the whole continent. In 1475 Huayna Capac, surnamed the Great, having ascended the throne of the incas, subdued the kingdom of Quito, and, making the city of Quito his capital, governed his vast empire from that city for 38 years. At his death he divided his possessions between his two best beloved sons, Huascar and Atahuallpa. To Huascar he gave the ancient empire of the incas, and to Atahuallpa the kingdom of Quito. As might have been expected, this arrangement, in the course of a few years, caused dissatisfaction; whether the fault lay with Huascar or Atahuallpa is now uncertain, but their discord soon led to civil war, and in its vicissitudes Huascar was defeated and imprisoned in his own capital in 1531. Atahuallpa now ascended the imperial throne, and reigned with great splendor; but his career was short. The Spaniards had already been led to the Pacific coasts of South America by their thirst for gold, and Francisco Pizarro landed at Tumbez, now Guayaquil, in 1532, with the audacious design of conquering a great empire with a force of 250 men. Pressing forward with his little band across the lofty sierras, he at length reached the city of Caxamalca, where Atahuallpa was solacing himself after the fatigues of a journey over his empire, and within two days, by an act of the basest treachery, had made the inca a prisoner, and slaughtered his body guard. Atahuallpa, perceiving the thirst for gold which actuated the Spaniards, offered to fill the room in which he was imprisoned to a certain height with the precious metal, if he might thus purchase his freedom. The Spaniard apparently assented to the proposition, and the gold was nearly all collected when Pizarro seized it, and, after a mock trial, put the inca to death. Huascar had previously been assassinated in prison, as is believed, by order of Atahuallpa, and at the death of the latter his vast dominions fell an easy prey to the invaders. They were erected into a viceroyalty of Spain, and the kingdom of Quito became a presidency of that viceroyalty. For 275 years, the present territory of Ecuador vegetated under Spanish misrule, making little progress either in morals or intelligence, but yielding—which was the principal concern of the mother country—a rich harvest of the precious metals. During a part of this period it was one of the richest and most productive of the colonies of the Spanish crown; but the patience of the Indians, too long tried, at last gave way, and in many of the mining districts they slew the proprietors and destroyed all traces of the mines. It was not until 1809 that the colonists, disgusted with the oppression of the home government, raised the cry of liberty at Quito, and in some 5 or 6 battles made a desperate effort to attain it, but were defeated. In 1820 the effort was repeated at Guayaquil, and this time, under the guidance of Bolivar, with success. In July, 1821, Ecuador, New Granada, and Venezuela were constituted a republic under the name of Colombia, and for 3 years subsequently maintained a series of conflicts with the Spanish forces. The battle of Ayacucho, in December, 1824, finally destroyed the Spanish power in these states. In 1828–'9 Peru attacked the Colombian states with a force of 8,000 men, but was defeated by the Colombian force, which amounted to only half its number. In 1831 Ecuador followed the example of Venezuela, and separating from the Colombian confederacy, became an independent republic. From that period up to 1852 the history of the republic was little else than a series of *pronunciamientos* and attempted revolutions, in the instigation of which Gen. Flores, an ambitious man, at one time president, attained a preëminence. Since 1852 he has ceased to foment difficulties in the republic, and the people have made considerable advance in population, industry, and intelligence. The president of Ecuador is now (April, 1859) Gen. Francisco Robles, who was elected in 1856. The French decimal system in the currency, weights, and measures, was adopted, Dec. 5, 1856, and has been in operation since Oct. 15, 1858. A treaty with Peru and Chili for mutual protection against fillibusters was concluded in the early part of 1857, but the good understanding between Peru and Ecuador has of late been interrupted. Guayaquil was blockaded by the Peruvian

forces, and the blockade was still continued, March 19, 1859, when President Robles removed the seat of government from Quito to Guayaquil. In March, 1859, an association was organized by German merchants in London with a view to direct the emigration from Germany to the republic of Ecuador. The district of Pailon, about 100 m. from Quito, has been selected for the establishment of the first settlement.—See Juan de Velasco, *Histoire du royaume de Quito* (French edition, Paris, 1840); Gaetano Osculati, *Esplorazione delle regioni equatoriali* (Milan, 1850); F. Walpole, "Four Years in the Pacific" (London, 1850); and Manuel Villavicencio, *Geografia de la Republica del Ecuador* (New York, 1858).

EDDA, the name of two collections of ancient poems of the Northmen, or early Scandinavians, from which is chiefly derived our knowledge of Scandinavian mythology. The Eddas, and in some instances the Sagas, were composed originally in Denmark, in Sweden, and doubtless also in Norway, where the language now known as Icelandic was longest preserved in Europe. This was the general language, and its literature is the common property of the North. The first of the Eddas is called the old or poetical, sometimes the Sämundic Edda. The word in Icelandic means ancestress, and the old Edda is the mother of Scandinavian poetry. What has been preserved of it consists of 39 poems, written at a remote and unknown period by anonymous pagan authors, and collected by Sämund Sigfusson, an Icelandic priest, who was born in 1056. He was educated in France and Germany, and after a sojourn in Rome, returned to Iceland, where he devoted himself to study and the education of the young. A copy of his Edda on vellum, the best which is preserved, was found in Iceland by Bishop Brynjúlf Sveinsson, in 1643, and published under the title of *Edda Sämundar hinns Froda* (Copenhagen, 1787–1828, 3 vols.), with an excellent *Lexicon Mythologicum*, by the learned Finn Magnussen, the editor of the last volume; there are also editions by Afzelius in Swedish (Christiania, 1818), by Munch (Christiania, 1847), by Schimmelmann in German (Stettin, 1777), by Studach (Nüremberg, 1829), and by Simrock (Stuttgart, 1851; 2d ed. 1855). The different poems may be classed according to the nature of their subjects, as mystical, didactic, mythological, and historical, containing elements more ancient than the Christian era in the North. The most remarkable in the 1st classification is that which bears the title *Völuspa*, the oracle of the *Vola*, or prophetess. It is a rapid and obscure exposition of the cosmogony of the Scandinavians, from the creation to the destruction of the universe. The *Grougaldur*, or magical song of Groa, is a collection of the terms of magic. The *Solar-ljod*, or song of the sun, was almost entirely added by Sämund, in imitation of pagan poetry. The influence of Christianity, however, is recognized in various allusions to a future state, and to the existence and occupations of the soul after death. Of the 2d class, we find a poem in dramatic form, the *Vafthrudnis-mal*. Odin desires to contend in science with the wisest of the giants, Vafthrudnir. He assumes the form and garb of a wayworn traveller, seeks hospitality of the giant, and proposes the contest, the wager agreed upon being the head of the vanquished disputant. The trial begins with numberless questions on the mysteries of the religion of Odin. The giant soon perceives the wondrous strength of his opponent, as sitting side by side they discuss the marvels of sacred science. "Tell me," says Odin, "the future state of souls; tell me what heroes do in Walhalla?" The giant makes light of questions so simple. He expounds as to a child matters within the every-day compass of Scandinavian learning. At length the pretended traveller makes his final attack. "What words," he asked, "whispered Odin in the ear of his son Baldur, when Baldur lay on the funeral pyre?" The giant grew pale. He knew that Odin alone could know those whispered words. The god stood confessed before him. "My doom, my doom, great Odin," he cried; "let the deed of celestial destiny be done. Let it fall on him who has dared to talk of sacred science with Odin, wisest of gods!" The *Grimnis-mal* describes the 12 homes of the gods, the 12 signs of the zodiac. In the *Alvis-mal*, the dwarf Alvis, one of the genii charged with lighting the torch of the sun, has been betrothed to the daughter of Thor, and comes to claim his bride. The god entertains the spirit during the whole of the night, when at length the unfortunate Alvis, scenting the cool air of morning, is summoned brideless away to the sun. The *Hyndlu-ljod* is an obscure account of the genealogy of some of the northern kings, descendants of gods. The *Hava-mal*, the sublime discourse of Odin, is a collection of allegorical poetry and maxims in verse, ending with a chapter wherein the god explains the mysterious power of the runes against various misfortunes. The poem contains precepts also of commonplace wisdom, such as: "Dwell not too long with one host; he may weary of thee;" "One man may keep a secret, not two;" "That which three men know cannot be a secret." Other precepts in the same collection breathe less virtue than cunning and artifice. Among the poems purely mythological may be cited the *Hymisquida*, or song of Hymer, describing a feast given by a sea god to his brother divinites. The *Rafna-galdur-Odins*, the song of the raven of Odin, describes the gods lamenting the approach of their last day. The historic class of poems in the Edda is more abundant than the others. Reality, however, as in the poems of Homer, is enveloped in the supernatural. They narrate heroic days; and like the song of the *Nibelungen*, record the adventures of heroes who have been, more or less truly, identified with Dietrich, Sigurd, Siegfried, and Attila and his Huns, during their first inroads upon the provinces of Rome.—The prose Edda is ascribed to the celebrated Snorro Stur-

leson, who was born in 1178. It is a collection of the myths of the gods, and of explanations of the types and metres of the pagan poetry. It was gradually formed by the labors of several writers, although it usually bears the name of Snorro Sturleson alone. It was intended for the instruction of the young scalds, or poets, and shows that the old poetry of the Icelanders came to be cultivated as a learned art. The Edda of Snorro, obviously of less value than that of Sämund, is principally worthy of attention, in so far as it completes and aids the comprehension of the other. A complete edition was published in Stockholm in 1818, by Prof. Rask. The work had previously been imperfectly known in the edition of Resenius (Copenhagen, 1665), taken from corrupt manuscript, the text often confounded with the notes of the scalds. The introduction, or *Formali*, is a quaint compendium of Jewish, Christian, Greek, Roman, and Icelandic legend, illustrating the origin and chain of descent of the Scandinavian race from the heroes of Troy. The *Gylfa-ginning* follows, and relates the visit of Gylfe, a Swedish king and magician, to Asgard, in order to observe at its fountain head the spirit of northern wisdom. An English translation of the first part of the prose Edda is contained in "Mallet's Northern Antiquities" (Bishop Percy's translation, new edition, London, 1847). The second part of the prose Edda, called *Bragar-rädar*, represents Bragi, the god of poetry, at a feast given by Ægir, god of the sea, entertaining the celestial company with a narration of their own exploits. The epilogue, or *Eptimarli*, written by Snorro Sturleson or by a contemporary, is an attempted solution of the Edda fables by events of the Trojan war. At the end of the prose Edda we have the *Scalda*, a kind of *ars poetica*, or manual for the use of the young students of the art. We have already remarked that the German song of the *Nibelungen* recounts adventures and heroes of the Scandinavian poems. August Schlegel supposed the German poem to have been written about the year 1207. The Scandinavian poems are known to have been earlier, probably by several centuries.

EDDYSTONE ROCKS, a reef of dangerous rocks in the English channel, 600 or 700 feet in length, and about 9 m. S. W. from the Ramhead. They consist of 3 principal ridges, which are entirely covered at high water. A celebrated lighthouse on one of these rocks was begun in 1757 and finished in 1759. It is between 80 and 90 feet high, and furnished with 16 powerful Argand burners, giving a light of the first magnitude, visible in clear weather for 13 m. The first lighthouse on these rocks was built in 1696, of stone and timber. It was swept away in 1703, and another tower was constructed of wood 5 years afterward. This was destroyed by fire in 1755, and the present edifice was then commenced by the celebrated engineer, John Smeaton. The material employed was Portland stone, encased in granite, partly quarried from the rock itself, into which the foundations were dovetailed. The violence of the swell at the lighthouse renders communication with the shore extremely difficult, even in serene weather, and the sea frequently rises above the light, the strong plate glass of the lantern having been more than once broken by the waves. Three light keepers are employed here, and the house is always supplied with provisions for 3 months, and a stock of 500 gallons of oil.

EDEN (Heb., pleasure, delight), the Scripture name of the place where God placed Adam and Eve before the fall (Gen. ii. 8, 15, &c.). In the Septuagint it is called Paradise, that is, a park or pleasure garden. It was watered by a river which issuing forth branched into four streams, named Pison, Gihon, Hiddekel (or Tigris), and Euphrates. No locality can now be fixed for the garden of Eden, notwithstanding the efforts of learned men devoted to this topic. The geographical indications, as given in the book of Genesis, are too vaguely expressed to enable us to determine with any approach to certainty where it was situated. The most probable opinion seems to be that which assigns for the garden of Eden a place somewhere among the high mountainous regions of Armenia, where the rivers Tigris and Euphrates take their rise. Some writers, however, are of opinion that the garden of Eden is only a figurative expression, not intended to indicate any actual locality on earth.

EDENTATA, a small group of mammals, elevated into an order by Cuvier, and associated together rather by negative than positive characters; these are, a partial or total absence of teeth, the possession of very large claws embracing the ends of the toes, and a general slowness of motion arising from the organization of the limbs. One group consists of strictly vegetable feeders, the *tardigrada* of Illiger, including the sloths (*bradypus*, Linn.); the other group is principally insectivorous, including the ant-eater (*myrmecophaga*, Linn.), the armadillo (*dasypus*, Linn.), the pangolin (*manis*, Linn.), the aardvark (*orycteropus*, Geoff.), and the gigantic fossil *megatherium;* these are described under their respective titles. The term *edentata*, or toothless animals, is not properly applied to any of the group except the ant-eaters and the pangolins. The sloths are fitted for a life among the branches of trees, which they rarely leave, unless in search of fresh food, and then in the slowest and most awkward manner; the ant-eaters dig up their insect food with their powerful claws, and entrap them on their glutinous tongues; the armadillos, with their hard external covering, pursue insects on the ground, dig after vegetables and roots, and eat even decaying carcasses. The skull in the sloth is very short and round, in the armadillo longer and pointed, and in the ant-eater much elongated; in the megatherium there is a return to the short and solid skull of the sloth, and this animal seems in many respects intermediate between the tardigrada and the true edentata. The spine varies in the length and firmness of its

parts, according to the habits of the animal; the neck is long and capable of great rotation in the sloth, the 2 upper dorsals being so modified that they perform the functions of cervicals, with rudimentary ribs; the dorsal portion is very long, and contains more vertebræ than in any other mammalian group, viz.: 16 in the great ant-eater, 14 in the 3-toed and 23 in the 2-toed sloth; the ribs are remarkably broad, overlapping each other near the spine in some of the ant-eaters, giving thus great solidity to the chest and the necessary support for the digging fore limbs; the lumbar vertebræ are broad, with strong spinous, transverse, and articulating processes; the caudal vertebræ are 7 or 8 in the sloths, 40 in the great ant-eater, 45 in the long-tailed pangolin, and at least 18 in the megatherium; the V-shaped bones on the inferior surface are well developed in the true edentata, and in the megatherium; the anterior bone of the sternum is considerably developed in the whole group, especially in the ant-eaters and armadillos. The pelvis in the sloths and the megatherium is wide and capacious, and the ilia very broad; in the true edentates it is elongated, with the acetabulum behind the middle, and the ilia are very long. The anterior extremities in the sloth are remarkable for their length, the cylindrical arm, the separation of the convex bones of the forearm, and the length of the wrist, hand, and claws; the posterior extremities have the femur short, flattened, and strong, and the bones of the leg curved as in the forearm; the fibula forms a curious articulation with the astragalus, allowing great freedom of rotation, and the tuberosity of the os calcis is much elongated. In the true edentates, the anterior limbs are formed for digging, and therefore the scapular arch is well developed, the humerus short and robust, with strongly marked processes for muscular attachments; a clavicle is present in the ant-eaters and armadillos, but absent in the pangolins; the forearm has so large an olecranon that the ulna is nearly or quite twice the length of the radius; the bones are robust, and the hand is remarkable for the unequal size of the fingers, the middle one being in most of them much the largest; the peculiarities of the posterior limbs are less remarkable. There is an animal of Chili, called *chlamyphorus truncatus* by Dr. Harlan, which resembles the mole in its form and subterranean habits, and the strength and shortness of the legs; it comes near the sloths in the form of the teeth, and resembles the armadillo in the general characters of the skeleton; in the sternum and ribs it is like the *monotremata;* it is properly placed among edentata, and by Gray in the armadillo family. Another reason for separating the tardigrades from the edentates is found in the digestive apparatus. In the former the teeth are simple, formed for bruising leaves and stems; the stomach is complicated, divided into numerous compartments by internal folds, somewhat like the stomach of ruminants; the large intestine is readily distinguished by its size from the small, and by their partial separation. In the edentates, the teeth when present are simple, more numerous, and formed for crushing insects; the stomach is far less complicated, and the division into small and large intestine is not well marked. The peculiar subdivision of the arteries of the limbs in the sloths is not required in the active and terrestrial edentates; and the investing armor of the armadillo and the pangolin would be equally unnecessary for the arboreal tardigrades. The *edentata* seem to establish the passage from the *unguiculata* to the *ungulata*, as the nails are greatly developed, and cover in a great degree the ends of the fingers. That which especially characterizes them is the general absence of teeth in the anterior portion of the jaws, the dental apparatus being in most reduced to molars and canines.

EDESSA, the modern Oorfa, an ancient city of northern Mesopotamia, the capital of the province of Osroëne. Tradition ascribes its foundation to Nimrod, and supposes it to be on or near the site of the Ur of the Chaldees mentioned in Scripture (Gen. xi. 28). Under the Seleucidæ it was called Callirhoë, and under Antiochus IV. it took the name of Antiochia. In 137 B. C. it became the capital of an independent kingdom. The name Abgar or Agbar (the mighty) appears as that of its sovereigns, and its manufactories of arms were celebrated. Edessa was sacked by Trajan, by reason of the equivocal conduct of its rulers during the wars of the empire against the Armenians and Parthians. In 216 it was made a Roman military colony by Caracalla, who was murdered there in the following year. It played an important part in the early Christian church, was the residence of St. Ephraim, had famous schools of theology and more than 300 monasteries, and was for many years the principal seat of oriental learning. It was taken by the Arabs shortly after the death of Mohammed, and in the time of the first crusade became a Christian principality under Baldwin I., brother of Godfrey of Bouillon. Baldwin ruled it from 1097 to 1100, purchased Samosata and several other places, and abandoned his fief for the crown of Jerusalem. Baldwin II., cousin of the preceding, reigned from 1100 to 1118, was 5 years captive to the Turks, and was called in his turn to the throne of Jerusalem. Joscelin de Courtenay, the successor of Baldwin, was surnamed the Great by reason of his victories over the Saracens. Joscelin II., who reigned after him, was defeated by the sultan Noureddin, who captured Edessa and exterminated the inhabitants. It was plundered by Tamerlane in 1393, and in 1637 fell into the hands of the Turks, who changed its name to Orfah or Oorfa. The modern town is a large, well built place, with a wall 7 m. in circuit, and 40,000 or 50,000 inhabitants. Its grand mosque is a structure of considerable architectural merit, within which are held several schools for the instruction of young men in religion and law. It derives great commercial importance from its position on the route

between Aleppo and Koordistan.—EDESSA (probably the later name of the ancient *Ægæ;* the modern Vodena or Vodhena), the ancient capital of Macedonia, was situated on the Egnatian way, at the entrance of the pass leading from the mountain provinces into upper Macedonia, and also by another branch into Pelagonia and Lyncestes. The town was the cradle of the Macedonian dynasty, and even after the removal of the seat of government to Pella, in the plains below, Edessa continued to remain the national sanctuary and the burial place of the Macedonian kings. From its commanding position it continued to be of importance under the Roman and Byzantine emperors. Taken by Basil II., the conqueror of Bulgaria, it was strongly fortified under his reign (976–1025), and was called Bodina, whence the modern name. The modern town, which has few remains of antiquity, is situated in European Turkey, about 40 m. from Salonica, on the Vistritza river. The locality is as celebrated for its picturesque scenery in the present day as it was in ancient times.

EDFOO, the Atbo of the ancient Egyptians, and Apollinopolis Magna of the Greeks and Romans, a city of upper Egypt, on the Nile, 50 m. S. of Thebes. It has about 2,000 inhabitants, and manufactories of earthenware. Here are remarkable ruins of two temples partly covered by sand, whose architecture is that of the age of the Ptolemies, after Egyptian art had begun to decline.

EDGAR, an E. co. of Ill., bordering on Ind.; area, about 600 sq. m.; pop. in 1855, 13,920. It is drained by Embarras river and by Brulette and Clear creeks, two affluents of the Wabash. The surface is nearly level, and occupied partly by prairies and tracts of timber. The soil is fertile and suitable for grain and pasturage. Pork and wool are exported in considerable quantities. In 1850 the productions were 1,250,278 bushels of Indian corn, 49,424 of wheat, 138,830 of oats, and 174,828 lbs. of butter. There were 19 churches in the county, 1 newspaper office, and 690 pupils attending public schools. Named in honor of Col. John Edgar, one of the earliest and most distinguished settlers of the state. Capital, Paris.

EDGAR, a king of the Anglo-Saxons, son of King Edmund I., born about 943, succeeded his brother Edwy upon the throne in 959, died in 975. His reign was one of the most fortunate in the ancient history of England. He conquered the Scotch, is said to have reduced a part of Ireland, deterred both the foreign and domestic Danes from making any hostile movement, and improved the internal government of the kingdom. His vigor and foresight placed the country in so good a posture of defence, that the most of his reign is an interval of peace amid the constant wars waged by his predecessors and successors, and he has received from posterity the surname of "the Peaceful." Under the guidance of St. Dunstan he favored and reformed the monasteries, and restored the ecclesiastical discipline, which had been relaxed during the storms of Danish invasion. Yet the manners of Edgar himself were dissolute, and for bearing off a young lady educated in the convent of Wilton, he was ordered by St. Dunstan to abstain from wearing his crown for 7 years. The well-known story transmitted by Malmesbury on the faith of an ancient ballad, of his marriage with his second wife Elfrida, is the subject of an English tragedy by William Mason, and of a French opera by Guillard.

EDGAR ATHELING (that is, Edgar the Noble), an Anglo-Saxon prince, in the second half of the 11th century. The grandson of Edmund Ironside by his exiled son Edward, he was born in Hungary. In 1057 he followed his father to England, after whose sudden death in 1066 he became himself the heir to the crown, being the nearest relative to Edward the Confessor. Yet he was both young and feeble, and presented no claim, while the two resolute leaders Harold and the Norman William fought for the kingdom at Hastings. After that battle he was received at court by William the Conqueror, confirmed in the earldom of Oxford, which had been granted him by Harold, and treated with the greatest kindness. He accompanied the king in his visit to Normandy, but after his return, persuaded by the discontented Northumbrian lords, he took refuge with his followers in Scotland, and sought to lead a rebellion in Northumberland. Failing in this and in other enterprises, he returned to England in 1073, having previously rendered his submission to the king and received pardon. He was afterward engaged in a Scottish war to place a relative upon the throne of that country, and is thought to have gone to the Holy Land in the crusading army of Robert, duke of Normandy. His titles rather than his abilities make him a historic character, and the best result of his career was the introduction of something of the superior cultivation of the south into Scotland. (See ATHELING.)

EDGARTOWN, a post village, township, and seat of justice of Dukes co., Mass., on the E. side of the island of Martha's Vineyard; pop. in 1855, 1,898. The harbor is well sheltered, 4 or 5 fathoms deep, having a lighthouse with a fixed light 50 feet above the sea, erected on a pier 1,000 feet long, at the entrance to the harbor. It has 3 churches, 1 newspaper office, and in 1855 contained 1 manufactory of salt, 1 of oil and candles, 1 sail loft, and 2 boat-building yards. It had 12 vessels with an aggregate burden of 3,863 tons, a capital of $390,000, and 360 hands employed in the whale fishery.

EDGECOMBE, a N. E. co. of North Carolina, watered by Tar river, and by Fishing, Sandy, and Contented creeks; area, about 600 sq. m.; pop. in 1850, 17,189, of whom 8,547 were slaves. The soil is fertile and sandy. The surface is mostly level, and occupied in part by pine forests, from which quantities of turpentine are obtained. The staples are Indian corn and cotton, and the productions in 1850 were 759,373 bushels of Indian corn, 4,046½ tons of hay, and 3,097½ bales of cotton. The county was organ-

ized in 1783, and named in honor of the earl of Mount Edgecombe. Capital, Tarborough.

EDGEFIELD, a W. district of South Carolina, separated from Georgia by the Savannah river, and bounded N. by the Saluda; area, 1,540 sq. m.; pop. in 1850, 39,262, of whom 22,725 were slaves. It has a fertile soil and a moderately hilly surface, occupied by extensive plantations of Indian corn, oats, and cotton, and by large grazing districts. In 1850 the productions were 25,880 bales of cotton, 1,155,489 bushels of Indian corn, 62,810 of wheat, 285,926 of oats, and 166,757 of sweet potatoes. Numbers of cattle and swine are also raised. In 1850 there were 52 churches in the district, 2 newspaper offices, and 921 pupils attending public schools. Water power is abundant, and there are numerous mills and factories. The Savannah river is navigable for steamboats to the S. part of the district, and by small boats a still greater distance. Capital, Edgefield Court House.

EDGEHILL, a high ridge in the co. of Warwick, England, noted as the scene of the first battle between Charles I. and the parliamentary forces, in 1642. On the side of the hill is cut the colossal figure of a horse, whence a valley below has been named the Vale of Red Horse.

EDGEWORTH, Richard Lovell, a British inventor and author, born in Bath, England, in 1744, died in Edgeworthtown, Ireland, June 13, 1817. Of an ancient Irish family, he was educated at Trinity college, Dublin, and was afterward sent to Oxford. Before he was 20 years of age, he ran off with a young lady of Oxford, was married, and entered upon a life of gayety and fashion near Reading, in Berkshire, where his daughter Maria, afterward distinguished as an authoress, was born. From his boyhood he had been accustomed to make mechanical contrivances and philosophical experiments, and now in his eagerness for early racing news he constructed the first telegraph in England over a distance of 16 miles. He made several other inventions, all of which he abandoned before perfecting them, and which therefore led to no other result than gaining for him from the society of arts a silver medal in 1768, and a gold medal the next year. His favorite scheme at this time was to construct a locomotive which should carry with itself a short railway, upon which it should at the same time always run. He entered upon his patrimony in Ireland in 1782, and determined to devote himself particularly to the improvement of his estate, and the education of his children. He attempted to educate his eldest son on the plan which Rousseau had developed in his *Émile*. He put him into loose jacket and trousers, with naked arms and legs, and allowed him to run wild and do what he pleased. The young savage grew up to all the virtues except those which are needed in a civilized state. He hated books, hated every sort of government, hated to do any thing useful, but finally went to sea. Mr. Edgeworth was an enthusiastic member of the Irish volunteers, one of the earliest advocates of reform in parliament, and a member of the last Irish house of commons. He was involved in the troubles of the rebellion in 1798, and obliged to retreat with his family from his house, which however was saved from pillage on account of the esteem in which he was held personally. He was 4 times married, one of his wives having been Miss Honora Sneyd, the betrothed of Major André; his children were educated entirely at home under his own care. He wrote slowly and coldly, thought with logical precision, explained clearly, but yet could not express with his pen the passionate ardor with which he undertook any subject, and which he showed in his conversation. He preferred therefore to write in partnership with his daughter Maria, and in this way an "Essay on Practical Education" and an "Essay on Irish Bulls" were produced. He himself wrote several essays on railroads, telegraphs, carriages, and poetry. He took great interest in the literary pursuits of his daughter, who was accustomed to read to him her first rough plans and receive suggestions from him; and he also carefully revised her works and gave them his sanction before they were printed.—Maria, an English novelist, daughter of the preceding, born in Berkshire, Jan. 1, 1767, died in Edgeworthtown, Ireland, May 21, 1849. She was 15 years of age when her father succeeded to the family estate in Ireland, where under his direction she pursued her studies, formed habits of sharp observation, and developed that cheerfulness which made her always beloved in society, and that hope and confidence which are requisite to a full exertion of the mental powers. Early indicating her taste for literary pursuits, she seems never to have wished to be married; and as it had been the delight of her father to assist in developing her talent, she in return loved to remain by the family hearth, gratifying his earnest but less gifted mind by her literary successes, and repaying in his old age those attentions which she had received in youth. The series of her novels began with "Castle Rackrent," in 1801, and continued without interruption till 1817, during which period there appeared from her pen "Belinda," "Popular Tales," "Leonora," "Tales of Fashionable Life," "Patronage," "Harrington," and "Ormond." These works were remarkable for their humane sympathies, their moral tendencies, and their utter disregard of the materials out of which it was then the fashion to construct romances. The public was surprised by novels which contained neither ruinous towers, terrible subterranean cells, nor mysterious veils, and in which the characters were neither peers nor foundlings. The aim of Miss Edgeworth, like that of Joanna Baillie in her dramas, was to make each novel an elucidation of one particular passion or vice. Thus in her tales of fashionable life, Lord Glenthorn is a striking embodiment of ennui, Almeria is a heartless, wretched lady of mere fashion, Vivian illustrates the perplexities of a feeble will, Emilie de Coulanges

shows the passions and manners of a fashionable French lady, and the fine story of the "Absentee" exposes the folly and mortifications of those Irish families of fortune who leave their native country seats to be scorned in frivolous though brilliant society in London. On the death of her father in 1817 her career of authorship was for a time interrupted. She did not resume her works of fiction till she had expressed her affection for him by completing the memoir which he had begun of his own life, and she also completed and published, under the titles of "Rosamond" and "Harriet and Lucy," some stories for juvenile readers which had been begun by him 50 years before. Among the most ardent admirers of her novels was Sir Walter Scott, who avows that it was her humorous, tender, and admirable delineations of Irish character which prompted him to attempt similar portraitures of his own country. In 1823 she spent a fortnight with Scott at Abbotsford, by whom the visit was subsequently returned at Edgeworthtown. She did not reappear as a novelist till 1834, when her exquisite story of "Helen" was published; and her career of authorship terminated with the child's story of "Orlandino," which appeared in 1847. With the exception of a trip to the continent and a short residence at Clifton, she passed the latter years of her life at Edgeworthtown, unspoiled by literary fame, loved in the family circle which daily assembled in the library, and admired by all as a pattern of an intellectual and amiable woman. Her novels and miscellaneous pieces were first collected in 14 vols. (London, 1825). New editions appeared in London in 18 vols. in 1832, in 9 vols. in 1848, and again in 1856 in 10 vols. 12mo. They have been often republished in the United States.

EDGEWORTH DE FIRMONT, Henry Allen, the last confessor of King Louis XVI. of France, cousin of the authoress Maria Edgeworth, born in Edgeworthtown, Ireland, in 1745, died in Mitau, Russia, May 22, 1807. His father, an Anglican clergyman who became a convert to Catholicism and went to reside in France, borrowed the name of Firmont from an elevation on his estate. Henry, after having studied under the Jesuits at Toulouse and at the Sorbonne in Paris, was admitted to orders, chosen for confessor to Elizabeth, grand-daughter of Louis XV., and gained general esteem by his virtues and piety. He was selected by Louis XVI., after that monarch's condemnation to death, to render him the consolations of religion. He braved the popular indignation by passing with the king his last days, and ascending the scaffold with him. Just before the fall of the fatal axe, he addressed to him the words: "Son of St. Louis, ascend to heaven." He returned to Ireland in 1796, and was offered a pension which he refused to accept. He afterward accompanied the count of Provence (Louis XVIII.) to Russia, where his death was occasioned by his solicitous attentions to the French prisoners of war. He left a volume of "Memoirs," published in English by C. S. Edgeworth (London, 1815), and in French by Dupont (Paris, 1815). His letters have also been collected and published.

EDICT (Lat. *edico*, to declare), in Roman law, a general order published by the prætor when he entered upon his office, containing the system of rules by which he proposed to administer justice during the year of his office; also an annual proclamation made by the ædiles. In actual practice it was not, however, a new ordinance compiled every year by either the prætor or ædiles, but was substantially the same ordinance reënacted with some occasional modifications. The prætorian edict was revised or recompiled in the reign of Hadrian under the name of *edictum perpetuum*, after which it remained unaltered. The same term was applied to an ordinance or decree enacted by the emperor without the authority of the senate. It has also been used in modern legislation to express a decree of a monarchical government in relation to some specific subject, as the edict of Nantes.

EDINBURGH (Celtic, *Dun-edin*), the metropolis of Scotland, finely situated on a congeries of hills, about 2 m. from its port of Leith, on the S. side of the firth of Forth, 337 m. in a direct line N. N. W. from London, but by railway, *via* Trent valley, 398½; lat. 55° 57′ N.; long. 3° 11′ W.; pop. of the city and suburbs in 1851, 160,302. The city is surrounded on 3 sides, at greater or lesser distances, with a number of hills, forming a picturesque background to the view. High above the city, on the W., towers the castle, on a rock 300 feet high, while to the E. rise the heights of Calton Hill, Arthur's Seat, 822 feet above the sea, and Salisbury Craigs, 547 feet, separated from each other by a deep ravine. The appearance of the city and surrounding landscape is exceedingly picturesque; viewed from whatever point, whether from the ramparts of the castle overlooking the new town, from the crags or Calton Hill, or from the lower parts of the city looking up at the heights, the scene is equally striking. The city proper is 2 m. in length by 2 in breadth, or including Leith and the suburbs, 2¾ by 3½. From its many open spaces, it covers more ground in proportion to its population than most other British cities. Its situation is exposed, but salubrious. Snow seldom lies long. Neither summer heat nor winter cold is excessive, the mean temperature of summer being 57° 2′, of winter 38° 4′; annual fall of rain, 24 inches; proportion of deaths, 1 in 36.45. The streets are paved and lighted, and the city is supplied with water at the rate of 25 gallons daily to each inhabitant. The merchants form an incorporate guild under a charter from Charles II., and there are also 14 incorporated trades. Government is vested in 31 town councillors, a dean of guild elected by the guild, and a convener of trades chosen by the representatives of the incorporated trades. These 33 officers select from their number a lord provost, 4 bailies, and a treasurer. The city became insolvent in 1833,

and its property has since been held by trustees. The revenue of the corporation in 1854 amounted to £24,000. A police force of 327 men is maintained at a cost of £38,746, payable from an assessment of 1*s.* 2*d.* per £ rental. Paupers are supported by an assessment, exclusive of the many munificent charities. In 1853 the number of permanent paupers was 4,599, costing per head £8 10*s.* for adults, and £7 10*s.* for children at nurse, the amount of assessment being £42,062.—Edinburgh has but little commerce or manufacturing industry. There are 28 breweries of strong ale, 16 carriage factories, and several shawl weavers. Glass blowing and lace making are carried on to a small extent. Edinburgh is, however, the seat of an extensive book trade, and second only to London among British cities in printing and publishing, engraving, and all other ancillaries to literature. There are nearly 70 printing offices, with 1,200 employees. The number of periodicals and reviews published in 1858 was 20, and of daily and weekly newspapers 26, 8 of which have been established since 1855. A considerable passenger traffic arises from the number of railways which centre in the city, viz.: the Edinburgh and Glasgow, North British, Caledonian, Grantown, and Dalkeith, together with the Union canal, which connects the firths of Forth and Clyde. There are 10 joint stock banking companies, of which 5 are Edinburgh institutions, and 5 branches. Regular markets are held thrice a week, with cattle and horse fairs in the first week of November, and on the first and second Mondays of April.—The chief judicial authority of Edinburgh is the court of session, which is the supreme civil court of Scotland. It consists of 13 judges, constituting an inner and an outer house; the inner house comprises the "first division," presided over by the lord president and 3 senior puisne judges, and the "second division," under the lord justice clerk and 3 senior puisne judges; the outer house consists of the remaining 5 puisne judges officiating as lords ordinary, each sitting singly. An appeal lies from the decision of a lord ordinary to the inner house, and thence only to the British house of lords. A court of exchequer still nominally exists, but its functions are discharged by 2 judges of the court of session acting as barons of the exchequer. The lord president (as lord justice general), lord justice clerk, and 5 puisne judges of the court of session, also constitute the court of justiciary, having supreme criminal jurisdiction, which sits as occasion requires, with periodical circuit assizes. Lawyers privileged to practise before the supreme courts must belong to the faculty of advocates, which consists of 400 to 500 barristers, or to that of the writers to the signet, comprising 600 to 700 members. An ancient court called the convention of royal burghs meets annually in Edinburgh, the provost presiding; and a commissary court still exists, although its functions are almost merged in the court of session.—Edinburgh is divided into the old and new towns, the former picturesque and dirty, the latter unsurpassed for regularity and elegance. The old town mainly occupies a ridge between the castle on the W. and Holyrood house on the E., and includes on the S. a hollow occupied by an old street known immediately S. of the castle as the West-port, and further to the E. as the Cowgate. N. of the old town, and separating it from the new, was formerly a small body of water called the North loch, which is now drained and occupied by a market place, abattoirs, railway termini, &c. In the old town can be seen the peculiarities of the domestic architecture of former times in the dwelling houses of 5 and 6, and even of 11 stories, including attics, laid out in flats, or separate tenements on the successive floors, with a stone staircase common to all. In the new town the houses are almost universally 3 stories in height, with attic and sunk basement, and of tasteful architecture. The whole city is built of stone. The castle crowns the summit of a precipitous rock. It is a picturesque object, but far from impregnable; it has quarters for 2,000 men. It dates as a place of defence from the 5th century, but its present fortifications are modern. Its curiosities are the crown, sceptre, sword of state, and wand constituting the regalia of Scotland; Mons Meg, a huge cannon, constructed, it is supposed, at Mons, Flanders, in 1496, of bars and hoops; an armory capable of stacking 30,000 muskets, and a lately discovered chapel of the 10th century. A prominent feature of the old town is its principal street, the High street, of historic celebrity, which is one mile long, and in some parts 90 feet wide, and, under the continuous names of Castle Hill, Lawnmarket, High street, and Canongate, occupies the crest of the ridge from the castle to the valley in which lies the palace of Holyrood. On High street is the high church, dedicated to St. Giles, the patron saint of the city, and noticeable for its tower surmounted by an imperial crown in masonry; after the reformation it was divided by interior walls into 4 places of worship, in one of which John Knox officiated; his house still stands in the vicinity. Behind St. Giles is parliament square, containing the old parliament house of Scotland, now used as a court house; also the advocates' and signet libraries. In the old town are also the exchange, the Tron kirk, and Victoria hall, a modern structure in which the general assembly of the Scotch church meets. At the foot of the Canongate is Holyrood house, formerly a residence of the kings. The edifice is of ancient date, but little if any of the present structure is older than the reign of James V. The building is quadrangular in form, with an open court 94 feet square in the centre, but has nothing imposing in its architecture. Within the palace is the chamber of Mary, queen of Scots, in which her bed, though in a decayed state, may still be seen. Charles X. of France, after his flight in 1830, resided for some time in the palace, and Queen Victoria, whose statue adorns it, resides there on her visits to Edinburgh. In the gallery are mythical portraits of 106 Scot-

tish sovereigns. Adjoining the palace are the ruins of an abbey founded in 1128, and the space around the abbey and palace to the distance of 100 yards toward the city, but countryward embracing a circuit of 5 m., including Salisbury Craigs and Arthur's Seat, is a sanctuary in which debtors are privileged from arrest. The Cowgate, once an aristocratic but now a mean street, winds tortuously along the base of the hill, with a fringe of squalid alleys, until it expands into the Grass market, a spacious rectangle, in which is the new corn exchange, facing the spot where the Covenanter martyrs were executed in the latter half of the 17th century. A little S. stands Heriot's hospital, on the site called High Riggs. The heights of the old town are connected with the new by the south and north bridges on the line of Nicholson, a spacious street. The south bridge, and at another place George IV.'s bridge, span the Cowgate high above the roofs of the houses, while the north bridge throws its 3 principal arches across the hollow formerly occupied by North Loch. Nicholson leads into Prince's street at the theatre, a plain structure, and opposite the register house, a square fireproof building for the preservation of records, which has in front a bronze equestrian statue of Wellington. To the right, along Waterloo place, is Calton Hill, 344 feet above sea level, rising with an abrupt face to the E., but the whole covered with verdure except where it is dotted with monuments. Of these the most conspicuous are Nelson's, a tall circular tower; the national monument to the memory of Scotchmen who fell in the Napoleonic wars, which was intended to be a facsimile of the Parthenon, but for lack of funds only 12 columns have been erected; a monument to Prof. Playfair; one to Dugald Stewart, in imitation of the choragic monument of Lysicrates at Athens; and a Corinthian temple, with a statue to Robert Burns. On the hill are also the high school and observatory, and at the base are the massive castellated buildings of the gaol and bridewell, which superseded the old "heart of Mid-Lothian," pulled down in 1817. From Waterloo place Prince's street runs in a direct line, forming a terrace along the edge of the gardens of North Loch, and directly fronting the castle. This is considered one of the finest promenades in Europe. On Prince's street stands the noble Gothic tabernacle erected as a monument to Sir Walter Scott. A little further are the royal institution, on the roof of which is a statue of Queen Victoria, and the national gallery, two classic structures, the 1st Grecian Doric, the 2d Ionic. An immense causeway, called the earthen mound, formed from the debris of excavations, here unites the old and new towns. At the head of the mound is a handsome edifice in the Tudor style, erected for the college of the Free Presbyterian church.—The ground plan of the new town is a regular parallelogram of 3,900 feet by 1,090, Prince's street forming the S. line, George street, 115 feet in width, the middle line, and Queen street the N., with cross streets every 250 yards. George street contains statues of George IV. and of Pitt, and, in St. Andrew's square, a fluted column 153 feet in height with a statue to Lord Melville. Continuous from the new town extends another parallelogram, containing numerous fashionable streets and squares, as Great King street, Moray and Drummond places, &c. South of the old town are the "Meadows," a level park 1¼ m. in circumference; also Bruntsfield links, a sandy plain much used as a field for the national game of golf. Further are the pleasant suburbs of Newington and Morningside, the latter containing the lunatic asylum. Dean bridge spans the water of Leith at a height of 109 feet above the river bed, and connects the new town with the country to the N. Leith, the port of Edinburgh, lies about 2 m. N. of the city, and is approached by a spacious street called Leith walk.—Edinburgh, including Leith, possessed, according to the census of 1851, 123 places of worship, providing accommodation for 81,873 persons, equal to one seat for every two of the population, and classified as follows: Baptist 7, Catholic and Apostolic church 1, Episcopal 10, Established 26, Free 29, Friends 1, Glassites 1, Independent 6, Isolated 8, Jews 1, New Church 1, Original Seceders 1, Primitive 1, Relief Presbyterian 1, Roman Catholic 4, Unitarian 1, United Presbyterian 20, Wesleyan 4. The 15 city churches of the establishment are in charge of the civic corporation, who appoint the 18 ministers and pay them from a tax of 6 per cent. on the city rental. This tax is a source of heartburning to citizens of other denominations, but has been collected for 2 centuries. At present it amounts to about £10,000 net per annum, giving to each minister an average stipend of £568. The 25 ministers of the Free (or opposition) church receive from voluntary sources an average emolument of £289 each. The annual assembly of the churches of Scotland, Established and Free, meet annually in May. Each has a training school for teachers, and seminaries for divinity students.—The university of Edinburgh was founded in 1582, with a charter from James VI. The corporation of the city have the appointments to the greater number of the chairs, the crown having the nomination to the others, excepting 3. There are 32 professorships, divided into the 4 faculties of theology, law, medicine, and arts, with power to confer the usual degrees of Scotch colleges, viz.: D.D., LL.D., M.D., and A.M. An act passed Aug. 2, 1858, gives power to commissioners (appointed by the queen in council) to revise the foundations, or bursaries, to regulate the elections of university officers, to prescribe the course of study and the amount of fees, to report on the expediency of founding a new national university of Scotland, and to make arrangements for converting the present universities into colleges of the said university. Average attendance of students at the university of Edinburgh, 1,500. The winter session commences Nov. 1, and closes at the end of April; the summer ses-

sion (mostly for medical studies) extends from the 1st Monday of May to the end of June. Students are non-resident, and little supervision is exercised over them. To qualify for a degree in arts, attendance and examination are exacted in the classes of Latin, Greek, mathematics, moral and natural philosophy, and rhetoric. Bursaries, or foundations, of an aggregate annual value of £1,172, are participated in by 80 students. A litigation on a legacy left by the late Gen. Reid for the promotion of musical education was concluded in 1855, and a sum amounting to about £62,000 placed at the disposal of the university. The present principal is the Rev. Dr. Lee; secretary, Alexander Smith, the poet. The college building consists of a single quadrangle, having its main front, 356 feet, on South Bridge street. It is of Roman architecture, heavy in design and massive in execution. Within the edifice is the museum, rich in objects of natural history, to which the late Prof. Edward Forbes bequeathed a valuable collection. The number of visitors in 1857 was 75,754, of whom about 4,000 were students. Until recently the library, which contains over 100,000 volumes, was entitled to a copy of every book published in Britain, but the privilege is now abrogated in consideration of an annual grant of £575, beside which it receives £1 from every student who matriculates, £5 from every new professor, and a percentage on the graduation fees in medicine and arts. The other libraries of Edinburgh are: the advocates' library, and that of the writers to the signet, beside 5 public collections. The advocates', which was founded in 1682 by Sir George Mackenzie, contains about 150,000 volumes and 2,000 MSS. The signet library has 70,000 volumes, and both are open to the public under most liberal regulations. The faculties of surgeons and physicians have each extensive libraries, as has also the royal society, incorporated in 1783, for philosophic research. The institutions named have also valuable museums of their respective specialities. The Free church college has 6 professors, with a course of study embracing divinity, church history, oriental languages, exegetical theology, apologetics and pastoral theology, natural science, logic, and metaphysics; session from the 1st Tuesday of November to the beginning of April. The high school is another celebrated educational establishment, dating from the early part of the 16th century. Its curriculum of study occupies 6 years, and embraces Latin, Greek, French, German, geography, history, natural science, with the ordinary branches of a commercial education. Average number of pupils 300 to 400; quarterly fees 7*s.* 6*d.* to £1 5*s.* for each class. The Edinburgh academy is an institution of a similar nature, with a 7 years' course of study, at a scale of fees calculated for the wealthier classes—£7 for the 1st year, increasing to £11 10*s.* the last. The following schools existed in 1854: Established church 20, Free church 22, United Presbyterian 10, Scottish Episcopal 5, Roman Catholic 4, not denominational 31; total 92, beside numerous private institutions, naval and military academy, 2 Dr. Bell's schools, with 600 pupils, Lancasterian, ragged, and industrial schools. The grants to elementary schools (in the whole county) from parliamentary votes, from 1833 to 1857 inclusive, amounted to £41,580.—An admirable peculiarity of the Edinburgh educational system is the number of charitable foundations, called hospitals, which perform the double duty of charity and education. Heriot's hospital, the chief of these, was founded by the bequest of George Heriot, goldsmith to James VI., for the maintenance and education of sons of burgesses unable to maintain them. Thirty boys were admitted into the hospital on its opening in 1659. At present it bestows a thorough education on 180, boarding them for 7 years, and presenting them with £50 when apprenticed. The revenues of the hospital having outgrown its expenditures, 12 free schools have been established, which educate gratuitously 3,000 pupils. Donaldson's hospital is a more recent foundation of a kindred nature, established by the legacy in 1830 of James Donaldson, a printer. It already contains 300 inmates. Both the above-named hospitals have extensive buildings, Heriot's S. and Donaldson's 1 m. W. of the city. In addition to these are the following hospitals, partly for education of youth, and partly for maintenance of poor citizens: Trinity, for aged burgesses, 108 inmates; merchant maiden, 100 girls; trades maiden, 48 girls; George Watson's, 86 boys; orphan, 100 boys and girls; John Watson's, 120 boys and girls; Gillespie's, 200 boys and 40 aged persons; Cauvin's, 26 boys; Stewart's, for boys; Chalmers's, for sick and disabled; Fettes's, for young poor; the royal infirmary, with 400 beds; also 3 poorhouses.—The royal institution building is the property of the board of trustees for manufactures in Scotland. This body was organized in 1727, with power to administer a grant of £2,000 per annum contained in the articles of union between England and Scotland, for the encouragement of manufactures and the fisheries. In 1809 a separate fishery board was organized, and for many years the funds of the board of manufactures have been applied to the encouragement of art, chiefly through the school of design. The seat of this school contains accommodation for the board of British herring fishery; the royal society of Scotland, the most influential of the learned societies, and which publishes its transactions; the society of antiquaries; the royal institution, incorporated for the encouragement of the fine arts; and the school of design, with fine collections of paintings and statuary. The last was established on a humble scale in 1760 as a drawing academy, in which Wilkie and many of the most eminent Scottish artists were educated. Having been enlarged into a general school of design for manufactures, architectural and general ornament, as well as the study of the antique, it has at present about 200 students, including several school teachers. Art is further

represented by the Scotch national gallery of art, the royal Scottish academy, and the royal association for the promotion of the fine arts in Scotland. Antiquities are represented by the society of antiquaries, and agriculture by the highland and agricultural society of Scotland, which has done much for the development of the farming resources of the country. Industry is further encouraged by the establishment of an industrial museum for Scotland, comprising a museum proper, laboratory lectures (attended in 1857 by 20 pupils, beside 40 students of the university class of technology), and a library which was formally organized in 1857. A site for the new museum has been acquired; the cost of the building will be about £40,000, and a vote of £10,000 was proposed to parliament in 1857, which, however, was postponed. Botany is fostered by the botanic garden, which is the only one in Scotland, and is supported by government; astronomy, by the observatory, presided over by the astronomer royal for Scotland, who, beside his ordinary duties, lectures on practical astronomy at the university. The observatory is situated on Calton Hill, and is the property of the government, which grants £100 per annum for its support. Its lat. is 55° 57′ 23.2″ N.; long. 3° 10′ 45″ of space, or 0h. 12m. 43.0s. of time, W. of Greenwich. An act authorizing the government to acquire the theatre royal and adjacent property for the erection of a new general post office was passed in 1858.—Edinburgh is of high antiquity. Its castle rock is said to have been a stronghold of the natives long before their subjugation by the Romans. It was known as *Castelh-Mynyd-Agned*, or the fortress of the hill of Agnes. Subsequently it was called in the Gaelic *Magh-dun*, in the British *Mai-din*, from which in English it came to be styled the Maiden Castle, and by the Latin writers of the middle ages *Castrum Puellarum*. To account for this appellation, a romantic story was invented that the British kings in times of war or trouble sent their daughters to this stronghold. At the beginning of the 7th century, when the Anglo-Saxons were dominant in the south of Scotland, the place began to be called Edwin's burgh, from Edwin the king of Northumbria, who occasionally made it his residence. The Celtic inhabitants turned the English phrase into *Dun-edin*, which is also descriptive of the natural features of the site—the words signifying "the face of a hill." About the middle of the 9th century Edinburgh seems to have been a considerable village, and the possession of its castle was often contested in the wars between the Scots and the Anglo-Saxons. When the Scots regained Lothian in the 11th century, Edinburgh castle began to be frequently occupied as a royal residence. In the reign of David I. the town was reckoned one of the 4 chief places of the kingdom, and in its immediate vicinity this monarch founded the abbey of Holyrood. The canons of the abbey built a suburb westward from their church till it met the town, and the part of the city thus created still retains the name of Canongate. In the 12th century, William the Lion, who made the castle his residence, added largely to the town and constituted it a royal burgh. In 1215 the first parliament of Alexander I. was held there. In June, 1291, the castle, with nearly all the other fortresses of Scotland, was surrendered to Edward I. of England. In 1313 it was stormed at midnight, Feb. 28, by the Scots under Randolph, earl of Moray, who destroyed it. It was retaken and rebuilt by the English under Edward III., who placed there a strong garrison and made it for a time his residence. In 1337 it was unsuccessfully besieged by the Scots under Sir Andrew Moray, and in 1361 was taken by stratagem by Sir William Douglas. During the reign of David II. it was the seat of numerous parliaments, and though not the unquestioned metropolis, was held to be the chief town of Scotland. In 1384 it was visited by Froissart in company with a party of French knights. He calls it the Paris of Scotland, and describes it as consisting of 4,000 houses, so poor that they could not afford the knights due accommodation. After the murder of James I. at Perth in 1437, Edinburgh became decisively the national capital. His son James II. was conveyed thither for security from the murderers of his father, and continued to hold his court there. He was particularly attached to the place, and granted the city a variety of privileges and immunities, favored by which it grew rapidly in wealth and population. James III. bestowed upon it a banner which is called the blue blanket, from its color, and is still preserved as a sort of palladium of the city. In 1508 Chapman and Millar, under a royal charter, introduced the printing press. In 1513 the city was desolated by a plague, and the magistrates and many of the burgesses fell with James IV. in the fatal battle of Flodden. During the minority of James V. Edinburgh was the scene of many tumults between rival factions. In a fight between the Hamiltons and the Douglases 200 men were slain in the streets. This affair is popularly known as "clear the causeway." In 1532 the college of justice was established, and the city thenceforth became the chief seat of law for the whole kingdom. At this time, too, the High street was first paved and lighted. In August, 1534, Norman Gourlay and David Straiton were condemned and executed for Protestantism. In 1544 the earl of Hertford with an English army landed near Leith and set fire to the city, but could not take the castle. To defend it from the English, it was garrisoned by French troops in 1548. In 1556 the preaching of John Knox the reformer caused an outbreak of disturbances, which by the aid of Queen Elizabeth of England finally resulted in the triumph of the Protestants; and the first assembly of the reformed kirk met in the city in 1560, under the sanction of the municipal authorities. In August, 1561, the young and beautiful Mary, queen of Scots, arrived from France. In 1565 she married Darnley at Holyrood, and in Feb. 1567, her husband was blown up with gunpowder while sleeping in the house

of Kirk of Field, where the university now stands. Mary's marriage to Bothwell at Holyrood, on the following May 15, raised such disturbances in Edinburgh that the queen and her new husband fled from the city, June 6, pursued by 800 horsemen. In the civil war that ensued Edinburgh was frequently the scene of battle and suffered severely. In 1581 the erection of the college was begun, and the first professor appointed in 1582. In 1603 the city ceased to be the seat of royalty by the accession of James VI. to the crown of England on the demise of Elizabeth. In 1633 Charles I. visited the city and erected the bishopric of Edinburgh, a measure which gave rise to great disturbances. In Oct. 1643, the solemn league and covenant for the extirpation of prelacy was signed in the High church. The city raised and supported a regiment of 1,200 men to assist the English parliamentarians against Charles. In 1650 the royalist Montrose was executed at the town cross, and 2 months later Charles II. was proclaimed king at the same place. Still 2 months later, and Cromwell, having defeated the Scots at Dunbar, took possession of the city, and subsequently of the castle. From 1663 to 1685, under Charles II., Edinburgh was the scene of the torture and execution of a vast number of Covenanters, martys to their faith. In 1736 occurred the famous Porteous mob. In 1745 Edinburgh was occupied by the forces of the young pretender, Charles Edward, who held it for 5 or 6 weeks, but did not succeed in reducing the castle.

EDINBURGH REVIEW, the oldest of the great British quarterly reviews, the first number of which appeared in Edinburgh in Oct. 1802. It was originated by several young men then resident in the Scottish capital, the most prominent of whom were Sydney Smith, Francis Jeffrey, Henry Brougham, and Francis Horner. "I proposed," says Sydney Smith, "that we should set up a review; this was acceded to with acclamation. I was appointed editor, and remained long enough in Edinburgh to edit the first number." He was succeeded in the editorial office by Jeffrey, who retained it till 1829. The "Edinburgh Review" was successful from the commencement; it reached a circulation of 9,000 copies in 6 years, and of 13,000 in 12 years; and its appearance marks an era in journalism. Such elaborate discussions of the principles of politics and taste, written with so much brilliancy and effect, and containing such intrepid criticisms, had not before been attempted in periodical literature. The organ of whigs, it appeared even more liberal from the tone and temper of its articles than from the measures and principles which it advocated, for it favored a free and full discussion, an open field and fair play to argument and wit. It was thus the medium through which the daring ideas in philosophy and political science, that had been elaborated in the 18th century, were made familiar to the general public. Its high literary character was due not only to the talent and refinement of its contributors, but also to the fact that the articles combined the philosophical treatment of subjects with the critical examination of books. The greatest offences of the review, while under the care of Jeffrey, were in some of the belles-lettres articles, especially those on the poems of Wordsworth, Southey, and Lamb, which were ridiculed severely, flippantly, and, as subsequently admitted by Jeffrey, who wrote the critiques, unjustly. Wordsworth was accustomed to class Robespierre, Bonaparte, and Jeffrey together, as the three most formidable enemies of the human race who had appeared within his remembrance. The last article of Sydney Smith was published in 1827. Sir James Mackintosh had then become an occasional contributor, and Lord Brougham continued to write many political articles. A few years before the withdrawal of Jeffrey he had secured the services of two contributors who maintained the character of the review, Thomas Babington Macaulay and Thomas Carlyle. In 1825 Macaulay, then a student at Cambridge, despatched to the editor without personal acquaintance or introduction his paper on Milton. It was immediately admitted, and from that time till he went to India in 1835 almost every number contained one of his brilliant essays, chiefly on the literature of England. He continued to furnish articles after his return, among which were those on Clive and Hastings, till he began the composition of his history of England. One of his last contributions was his invective against Barrère, "the Anacreon of the guillotine." The articles of Carlyle began in 1827, and continued almost regularly for 6 years. He now atoned for some of the early sins of Jeffrey, who had depreciated Burns, satirized the German literature, "cut up" Goethe, and sneered at Richter. Carlyle furnished a massive panegyric of Burns, and a series of elucidations of the principal German authors. Some of his papers too, as that on the "Signs of the Times," startled the ordinary contributors and supporters of the review by depreciating modern progress, and by regarding the triumphs of machinery as leading only to the subjugation of mind to matter. Upon the resignation of Jeffrey the editorship devolved upon Macvey Napier, known also as an editor of the "Encyclopædia Britannica." He retained the office till near his death in 1847. During this period the whigs came into power, and the review as their organ adopted therefore a tone rather defensive than offensive. It had at first been thought almost an incendiary publication, but a party which deemed it not liberal enough had established the "Westminster Review" in rivalry. Napier was succeeded in the editorship by Prof. Empson, a son-in-law of Lord Jeffrey, who in 1854 was succeeded by Sir G. Cornewall Lewis, who in the following year resigned it into the hands of Henry Reeve. Under its later editors the review has assumed a more serious and scholarly and probably less effective character than belonged to it formerly.

Among the prominent contributors since the disappearance of the original staff, have been Sir William Hamilton on topics of mental philosophy and education, J. R. M'Culloch on political economy and the progress of manufactures, Henry Rogers and W. J. Conybeare on the tractarian and latitudinarian movements in the Anglican church, Sir James Stephen on ecclesiastical history and biography, George Moir, G. H. Lewes, and R. Monckton Milnes. A selection of the best articles that had appeared in the "Edinburgh Review" from the commencement to 1833 was made by Maurice Cross (4 vols., London, 1833). Three indexes have been published: to vols. i.–xx. (1813), vols. xxi.–l. (1832), and vols. l.–lxxx. (1850).

EDINBURGHSHIRE, or MID-LOTHIAN, a maritime co. of Scotland, extending about 36 m. from E. to W., and about 18 m. from N. to S.; area, 397 sq. m.; pop. in 1851, 259,435. Its N. boundary is formed by the firth of Forth, and is studded with important towns and havens. The S. outline is very irregular, being deeply indented by Peeblesshire, from which it is partly separated by a continuation of the Moorfoot range. These hills, the highest of which is nearly 1,900 feet above the sea, occupy an area of nearly 50 sq. m. in the S. E. part of Edinburghshire, but are not entirely unproductive. Many fertile dales lie hidden among them, and a great part of their acclivities is under profitable cultivation. The Pentland hills, which extend from Peeblesshire N. E. into the centre of the county, are bleak and sterile, but afford some fine scenery. The soil, except in the valleys of the Forth and N. and S. Esks, is naturally of inferior quality, and most of the land is used for pasturage, but the farms are skilfully worked. The chief crops are wheat, barley, oats, beans, peas, potatoes, and turnips. Good breeds of sheep and cattle are reared, and milk and butter are sold at the Edinburgh and other markets. The minerals comprise coal, limestone, sandstone, and porphyry. The chief streams are the N. and S. Esks, Gala water, and water of Leith. The county is not extensively engaged in manufactures, though there are various establishments in the chief towns, bleacheries and grist mills on the water courses, and some large paper and gunpowder mills on the N. Esk. Whiskey and the famous Edinburgh ale are the other articles most extensively made. The Union canal and several lines of railway terminating at the capital are the most important channels of inland communication. Principal towns, Edinburgh, Leith, Dalkeith, Musselburgh, and Portobello. The county sends one member to the imperial parliament.

EDISTO, a river of South Carolina, formed by the union of the N. and S. Edisto, the former of which rises in the W. part of Lexington district, and the latter in Edgefield. They unite a few miles W. of Branchville, whence the course of the main stream is S. E. and S. It enters the Atlantic by 2 channels, between which lies Edisto island, about 20 m. S. W. from Charleston. It is navigable 100 m. from the sea.

EDMONDS, JOHN WORTH, an American jurist, more generally known for his advocacy of what is called "Spiritualism," born March 13, 1799, in Hudson, N. Y. He was graduated at Union college in 1816, was admitted to the bar in 1819, and in 1820 commenced the practice of his profession in his native city. In 1831 he was a member of the lower branch of the legislature of New York, and for the 4 years ensuing of the senate and court of errors. Retiring from the legislature in 1836, he spent most of the following two years on special missions from the federal government among the Indians on the frontiers. In 1837 he resumed the practice of the law in the city of New York. In 1843 he became one of the inspectors of the state's prisons, and for two years labored to introduce a reform in prison discipline, by substituting for corporal coercion the system of kindness. The effort was successful, and receiving the sanction of the legislature, inaugurated a new feature in the penitentiary system of the state. In 1845 he was appointed one of the circuit judges of the state of New York. In 1847 he was elevated to the bench of the supreme court, and in 1852 became a member of the court of appeals. At the close of 1853 he retired from the bench, and has since been engaged in the practice of his profession in New York. Early in 1851 he began to investigate the subject of alleged intercourse with the spirits of the departed, and in the summer of 1853 made a public avowal of his belief. The faith he teaches denies the ordinarily received doctrine of the divinity of Christ and his atonement for our sins, and inculcates the ideas that man can and does hold personal communion with the spirits of the deceased, and through it can learn what is the life into which we are ushered after death; that man is the creature of progression, from his birth through eternity; that such progress is the ultimate destiny of all; that it must in all be alike in love, in knowledge, and in purity, for it is also the destiny of each through eternity to be a ministering servant of the Most High in executing the laws of creation; that each may retard or hasten his own progression, but cannot prevent it, and that his immediate future for good or ill is of his own fabrication, for he passes into the next stage of existence precisely what he is in this life, with all his attributes and propensities as he has cultivated or perverted them here. In elucidation of these principles, Judge Edmonds has published several works, the most elaborate of which is entitled "Spiritualism" (2 vols. 8vo., New York, 1853).

EDMONDSON, a central co. of Ky., drained by Green river and Bear creek; area, 225 sq. m.; pop. in 1850, 4,088, of whom 325 were slaves. The surface is hilly or moderately uneven; the soil is fertile and suitable for grass and grain. In 1850 the productions were 193,095 bushels of Indian corn, 4,322 of wheat, 34,455 of oats, 86,980 lbs. of tobacco, 7,940 of wool, and 12,891 of flax. There were 5 church-

es, and 210 pupils attending public schools. Anthracite coal is abundant, and a considerable portion of the county is occupied by beds of cavernous limestone. The famous Mammoth cave is situated here. This county was organized in 1825, and named in honor of Capt. John Edmondson, who fell at the battle of Raisin river. Capital, Brownsville.

EDMUND I., a king of the Anglo-Saxons, son of King Edward the Elder, and successor of Athelstan, born about 923, ascended the throne in 940, died in 946. The restless Northumbrians immediately after his accession invaded Mercia, but the young king by a rapid march overawed them and forced them to submit, and to embrace Christianity. He had, however, hardly left the country when they again asserted their independence. Edmund next conquered the Britons of Cumbria or Cumberland, and conferred that territory on Malcolm, king of Scotland, on condition that he should do homage for it, and protect the north from all future incursions of the Danes. As Edmund was celebrating a festival in Gloucestershire, he perceived Leolf, a noted outlaw whom he had sentenced to banishment, enter the hall and insolently seat himself at the royal table. Inflamed by passion, he turned to seize the ruffian, when the latter stabbed him fatally in the breast.

EDMUND II., surnamed Ironside, a king of the Anglo-Saxons, son and successor of Ethelred II., born in 989, ascended the throne in 1016, died in the same year. Even before his accession he was recognized as the champion of the English cause against the Danes under Canute, but his abilities and hardy valor were unable to prevent the subjugation of the kingdom. Canute was proclaimed at Southampton at the same time that Edmund was recognized by the burgesses of London, and the latter city was immediately besieged by the Danish forces. Edmund, obliged to flee from his capital, raised an army in Wessex, and at Sceastoan in Gloucestershire gave battle to Canute, who was assisted by many disaffected English nobles and prelates under Edric. The battle raged for 2 days, and fortune seemed to have declared for Edmund, when a stratagem of Edric made the victory undecided. He again met his enemies at Brentford and at Otford, but by the perfidy of Edric sustained a decisive discomfiture at Assington. This nobleman, having insinuated himself into the favor of the English monarch, fled with his division at the very onset. The resources of Edmund were not exhausted; he was prepared to meet Canute with a new army, when both the Danish and English troops, wearied of the strife, obliged their kings to come to a compromise, and to divide the kingdom between them by treaty. Mercia and Northumbria were the portion of Canute, and the southern parts were left to Edmund, who is believed to have been murdered at Oxford, thus making way for the accession of Canute.

EDRED, a king of the Anglo-Saxons, son of Edward the Elder, successor of Edmund I., ascended the throne in 946, died Nov. 23, 955. The childhood of the 2 sons of Edmund rendering them incompetent to succeed him, Edred in an assembly of the prelates and thanes was chosen king, and consecrated, in the style of his charters, to the "government of the Anglo-Saxons, Northumbrians, pagans, and Britons." Though afflicted with a lingering disease, he marched into Northumbria and quelled the turbulent Danes. In this reign St. Dunstan rose to power, and important ecclesiastical and monastic reforms were undertaken.

EDRISI, an Arabian geographer, supposed to be the person mentioned by historians of his nation under the name of Abou Abdallah Mohammed ben Mohammed ben Abdallah ben Edris, who was a descendant of the Mussulman Edriside princes who reigned at Fez before the Fatimites, born in Ceuta in 1099, died in Sicily about 1164. He studied at Cordova, where he distinguished himself for his knowledge of cosmography, geography, philosophy, medicine, and even astrology, and for his skill as a poet. After visiting Constantinople, Asia Minor, Egypt, Morocco, Andalusia, France, and England, he repaired to Sicily, whither he was invited by King Roger II., a friend of learned men. He made for that prince a terrestrial globe of silver, upon which he inscribed in Arabic characters all that he knew of the various countries of the earth. To explain the globe, he composed a treatise on geography. The globe is lost, but a complete manuscript of the geography was discovered in the imperial library at Paris in 1829, of which a French translation by Jaubert appeared in 1836. Several portions and abridgments of the work had however been published many years before. Edrisi divides the earth into 7 climates or zones, each of which is again divided into 11 regions; and in his descriptions he adheres strictly to his scheme without considering whether his divisions resemble those which have been traced by natural features or society. His work represents the state of geographical knowledge among the Arabs in the 12th century, and although it contains nearly as many errors as there are in Strabo, it was yet the source from which the western geographers derived their notions prior to the Portuguese discoveries in the 15th century.

EDUCATION (Lat. *educo*, to draw out), the development of the faculties or germs of power in man, and the training of them into harmonious action in obedience to the laws of reason and morality. In a general sense, it embraces the universal means by which Providence is guiding the human race to its final destiny; or it includes the countless natural and social circumstances under the indirect tuition of which individuals pass from the cradle through the career of life; but it more usually and specially designates the instruction and care which parents and masters bestow upon the young to direct their physical, intellectual, æsthetic, and moral development. According to Plato, a good education consists in giving to the body and the

soul all the perfection of which they are susceptible; according to Rousseau, in making the primitive instincts and dispositions the constant guides of character and action; and according to Kant, there is within every man a divine ideal, the type after which he was created, the germs of a perfect person, and it is the office of education to favor and direct the growth of these germs. Yet education not only aims at the development and culture of the child as an individual, but is also the means by which every rising generation is put in possession of all the attainments of preceding generations, and becomes capable of increasing and improving this inheritance. It thus secures the regular progress of society, and has for its end to fashion childhood to an order of things and of ideas which it is designed to establish or perpetuate. Thus, according to Aristotle, "the most effective way of preserving a state is to bring up the citizens in the spirit of the government; to fashion, and as it were to cast them in the mould of the constitution." "The task of the instructor," says Herbart, "consists in transmitting and interpreting to the new generation the experience of the race." Education therefore has reference to the economy of society; it constitutes the apprenticeship of those who are afterward to take a place in the order of a civilized community; and, as universal knowledge and skill are impossible, it varies for the different states and classes of men, like the different pursuits of life.—In the earliest ages, the entire education and culture of the people were in the hands of priests, who were the first founders of institutions, the first savants, statesmen, judges, physicians, astronomers, and architects; and science has been separated from religion, and teaching has been a distinct profession, only in the most highly civilized communities. Even in these, learning and schools have often been to a greater or less extent, more or less directly, under the patronage and care of religious bodies, since religion has been esteemed by all nations the highest interest of society.—At a very ancient era, though less remote than they themselves pretend, the Chinese possessed a high degree of culture. The Chinese sage, Confucius (born 551 B. C.), was the restorer and not the founder of their civilization, and expressly disclaimed writing any thing which had not long been recognized in the legislation and science of his ancestors. The principles established by him and by Mencius (nearly 2 centuries later) still prevail in Chinese pedagogy. The course of instruction begins in the family, where the boys are taught to enumerate objects, to count to the number of 10,000, and to reverence their parents and ancestors by a minute ceremonial. At the age of 5 or 6 years they are sent to school. On entering the hall, the pupil makes obeisance first to the holy Confucius and then to his master. A lesson learned in grammar, history, ethics, mathematics, or astronomy, according to the proficiency of the student, is followed by the morning repast; after which the day is spent in copying, learning by heart, and reciting select passages of literature. Before departure at night a part of the pupils relate some of the events of ancient history, which are explained by the master; others unite in singing an ancient ode, which is sometimes accompanied by a symbolic dance. They leave the hall with the same obeisances with which they enter it, and on reaching home reverentially salute the domestic spirits, and their ancestors, parents, and relatives. For the sons of the nobles a higher course of instruction is provided in universities under the surveillance of the state. One of these exists in most of the large cities, and the most advanced of them is the imperial college in Pekin. Candidates for admission into the last are required to pass a strict examination, and the graduates from it are at once appointed to public office. In no other country, with perhaps the exception of Prussia, is a learned education the means of official promotion so much as in China. The education of girls is neglected, but the daughters of the wealthy are generally taught to read, write, sing, and sometimes to make verses.—Historians usually account the inhabitants of India the most highly educated of the ancient nations of the East. Yet Hindoo learning and science have always been almost exclusively in the hands of the caste of Brahmins, who only are allowed to explain the Vedas or sacred books to the two castes next in rank. The fourth and much the most numerous caste of Soodras, or laborers, are excluded from all privileges of education, and forbidden even to listen to the reading of the sacred books. The elementary schools are now held in the open air, and the instruction ordinarily begins with writing. The boys, sitting naked on the ground, write in the sand, or on palm leaves, a series of moral sentences from the ancient writings. These are also committed to memory. The Vedas are taught separately in the schools of the Brahmins, and embrace not only the higher doctrines of mythology, but also of mathematics, astrology, and philosophy. Hindoo masters especially inculcate the rules of politeness, the art of elegant conversation, the countenance which ought to be assumed according to occasions, and innumerable minute practices of etiquette and duplicity. The education of women, to whom the laws of Manu ascribe a mingled character of malice and deceit, is totally neglected, and it is a disgrace for them to know how to read. Only the courtesans learn to read, sing, and dance. Schools have been established by the British government, and also by the natives, in which there are generally two departments, in one of which the English language, sciences, and literature are taught, and in the other the Sanscrit, Persian, or Arabic languages and literature.—The early culture of the Egyptians was such, that the Greeks derived from them their first lessons in science and philosophy. In Egypt, too, the Israelites obtained the knowledge which enabled them to measure and "divide the land." Learning and political power were chiefly in the hands of the

priests, among whom the greater part of the lands were distributed. Public education existed only in the castes of priests and warriors, until it became more general after the rise of the Persian and Greek dominion. While the mass of the people were trained to the mechanical arts, a few only were instructed in the mathematical sciences, and in the doctrines of morality and divinity. An esoteric culture was reserved to the priests themselves, whose principal schools were at Thebes, Memphis, and Heliopolis. The allusions of the Greeks, and the inscriptions on the monuments, prove an early knowledge of geometry, astronomy, mensuration, and surveying in Egypt, and from the time of Thales the wisest of the Greeks went to study in that country. Iamblichus says that Pythagoras derived thence his information upon different sciences, and that he complied with the minutest regulations of the priests, in order to overcome their repugnance to imparting their theories. Plato, it is said, was a disciple of them, and states that "when Solon inquired of them about ancient matters he perceived that neither he nor any one of the Greeks had any knowledge of very remote antiquity." It was not unusual for female children of the priestly families to acquire an education, but the populace in general were trained only to follow in the occupation of their parents and kinsmen. At a later period a part of Egypt came within the circle of Greek civilization, and the schools of Alexandria and other cities of the delta became as renowned as those of Thebes and other more southern cities had formerly been. The two Alexandrian libraries, one of which was destroyed under Theodosius the Great, and the other by command of the caliph Omar I. (A. D. 642), were the most remarkable monuments of ancient learning.—The culture of the ancient Persians was the exclusive care of the magi, a priestly caste of Median origin, who were the savants of the empire, the legislators, judges, interpreters of dreams, astrologers, and highest functionaries at court. They ruled the Persians for ages by the force of intellect alone. To them were intrusted the preservation and establishment of the doctrines and laws of Zoroaster. There was no general system of national education, but the instruction was simple for the people, learned and religious for the magi, and military and political for the warriors. The faults of children were not regarded as sins till the age of 8 years, when they were first taught to say their prayers. The intellectual culture was but trifling except to those who were to inherit the learning of the magi, but the moral education inculcated the civil virtues and strict habits of truth and justice, while in physical training the Persians surpassed all other eastern nations. Their fundamental maxim was to combine a meagre fare with violent gymnastic exercises. According to Herodotus, "their sons were carefully instructed from their 5th to their 20th year in 3 things alone, to ride, to draw the bow, and to speak the truth." The *Cyropædia* of Xenophon is a romantic picture of the Persian mode of education. It presents the whole population divided into 4 classes according to age, and meeting at appointed times in the 4 divisions of the public edifices, which were far removed from the market places. The boys till the age of 17 years were taught to know and to practise justice, and to entertain right sentiments toward the divinity, their country, their parents, and their friends. They lodged at home, took their slight meals under the care of their masters, learned to handle the bow and javelin, and were prompted to admire and imitate those aged men who were noted for exemplary virtues. From the age of 17 to 27 years they passed their nights in the public edifice, that the purity of their morals might be strictly guarded, learned the arts of war, were accustomed to rise early, to bear cold and heat, to walk, to run, and to follow the chase. During the 25 following years they were accounted ripe men, and obeyed their superiors in war. Above the age of 52 they were reckoned among old men, renounced martial service, and administered justice in public and private affairs. Such an education and career was legally open to every citizen, but only the wealthier classes could avail themselves of the public schools, since it was necessary not only to dispense with the labor of their children, but also to pay their expenses.—The theocratic constitution of the Hebrew nation, and the foundation of its politics and ethics on religion, produced a mental cultivation as manifested in its literature very unlike that found among any other oriental people. The schools of the prophets are the only schools which are mentioned, but children were generally instructed by their parents in the law of Moses and the history of the nation. The obedience of children to the commands of their parents is a frequent injunction in the Scriptures. Girls were taught to sing, to play upon musical instruments, and to dance on solemn occasions; and many female poets and learned women figure in the history of the ancient Jews. After the exile the rabbins established schools to which children were sent from their 5th or 6th year, and in which, beside the teaching of the Scriptures, the commentaries and traditions, the Mishna and Gemara, were taught and committed to memory. The instruction was oral, no student ever taking notes, and the Mishna had long been transmitted from master to pupil before it was committed to writing. The most celebrated of the early rabbinical schools were those of Jamnia (long under the direction of Gamaliel, and at which Saint Paul studied), Tiberias, Alexandria, Babylon, and Jerusalem. During the greater part of the middle ages Jewish astronomers, physicians, poets, and philosophers were scattered through Spain, Italy, and France, and the cities of northern Africa and western Asia. Their greatest schools flourished in Egypt, Fez, Andalusia, and Languedoc.—Of the methods of Greek education, a connected account may be formed from the numerous scat-

tered allusions in classical literature. At the age of 6 years boys passed from the exclusive care of their mothers, who educated them till then along with the girls. Lullabies, cradles, baubles, rattles, dolls, miniature go-carts, and images of warriors and mythological scenes, are mentioned among the resources of the nursery. The children were terrified into good behavior by stories of bugbears and bogies, or by castigation, which was far from uncommon, and was administered usually with the slipper or sandal. The nurses and attendants used to tell tales for their amusement, consisting chiefly of the legendary exploits of the gods and demigods. Plato and Plutarch treat particularly of the moral influence of this story-telling, and urged that the nurses should be restricted in their selection of subjects. At about their 8th year the boys were intrusted to the care of a pedagogue, who accompanied them to school, carried their books, and kept them constantly under surveillance. He was a slave, but often intelligent and of polished manners. The schools were under the supervision, but not the patronage, of the state, and the fees received from pupils constituted the schoolmaster's income. Instruction began in the early morning, and was in 3 branches: the letters (comprehending reading, writing, and arithmetic), music (including also literature and art), and gymnastic exercises. Plato recommended that arithmetic be taught as an amusement, and that the abstract ideas of number be presented in as concrete a form as possible by the use of apples and the like. Having learned to read, the boy was made familiar with the works of the poets, and required to commit to memory long select passages. The poems of Homer, especially, were thought to contain by precept and example every thing calculated to awaken in youth a national spirit, and to impress the noblest virtues. The lyre was the favorite musical instrument at Athens, and instruction in playing upon it was a regular part of education. The flute was at one time popular, but its use was abandoned, according to Aristotle, because it distorted the face. Attendance at school was continued till the 16th or 18th year, after which those who wished became disciples of teachers of a higher order, the philosophers, rhetoricians, and sophists. From that age they began more to frequent the gymnasia for athletic exercises, the benches of which were often occupied by sophists conversing with their pupils and surrounded by a crowd of listeners. For girls there were neither educational institutions nor private teachers. Their whole instruction was derived from their mothers and nurses, and till marriage they were excluded from the society and conversation of the opposite sex. Hence, there were no scientific or learned ladies, with the exception of the *hetæræ*, and of these the Milesian Aspasia was perhaps the only one that was respected. Grecian education received its first strong impressions from the institutions of Lycurgus and Solon, and from the influence of the school of Pythagoras. That the child was the property, not of his parents, but of the state, was the central idea of the educational system established by Lycurgus in Sparta. All personal interests must yield to those of the nation. Every Spartan child, with the exception of the heir presumptive to the throne, was subjected to a severe military and public discipline, which consisted largely in gymnastic training, to the neglect of intellectual culture. They were not taught to read, but to speak with a precision which is yet proverbial. Truthfulness and masterly self-command were moral results which were well combined with physical endurance. Females were educated nearly the same as males, and the two sexes often strove together in gymnastic contests. Thus was formed a hardy and warlike nation, destitute and heedless alike of refined feelings, æsthetic tastes, and scientific knowledge. It was in obedience to the principles of the code of Solon that Athens became the centre and mother of liberal culture. Though education, like religion, was recognized as a part of the political constitution, yet the state left it to parental interests and affection to educate the young, ordaining only certain general rules, chiefly in behalf of morality. Thus every citizen, under a severe penalty, was required to teach his son to read and to swim; he was also to fit him for some occupation, otherwise the son would not be obliged to support him in his old age. Intellectual and æsthetic culture were always prominent in Athenian education, and gymnastic training was encouraged as much in the interest of physical beauty as of physical strength. In the time of Pericles the writers, statesmen, artists, and the populace united in appreciating the fine arts; every coin was stamped with a beautiful symbol, the poorest clay vessels were gracefully outlined, and the finest Athenian specimens of architecture and sculpture appealed to common sentiments of patriotism, religion, and taste. Pythagoras was the first of the Greek philosophers who founded a school or sect that survived him for centuries. He settled as a teacher in Magna Græcia, or southern Italy, after having travelled and studied in Egypt. He admitted into his society only those whose physiognomy pleased him, who obeyed their parents, were devoid of vanity, and had the art of keeping silence and listening. The disciple was first admitted only to the exoteric class, where he learned but a part of his master's dogmas. There he remained at least 8 years, during the last 5 of which he accustomed himself principally to silence. He was finally received into the esoteric class, where he was initiated into all the sciences, especially mathematics, upon which Pythagoras set the highest value. The basis of his system seems to have been the harmony of the universe, and our conceptions of order and of music; and it practically inculcated respect for women, simplicity in attire, severe honesty, devotion to ideas of beauty and virtue, and the blending of all the elements of character so that they should tend to a single

end. Socrates, Plato, and Aristotle subsequently developed the Greek theories in the higher departments of education, their speculations on the subject forming a part of their philosophical and political systems.—The Hellenic methods of education were in most respects copied by the Romans, who, however, at first laid greater stress on vigorous corporeal exercises and the nurture of the sentiment of patriotism. The ancient title of the schoolmaster was master of the games (*ludimagister*), and instruction was entirely independent of the state till near the time of the emperors. Numerous religious ceremonies preceded, accompanied, and followed the birth of a child, who during the republic was educated in the family successively under the care of his mother, his father, and a pedagogue or learned slave. After his 15th year, the noble young Roman assumed the *toga virilis*, and from that time for more than a year applied himself to gymnastic exercises designed to prepare him for war. He was afterward admitted to the society of public men to learn the art of statesmanship. After the Greek influence became predominant in Roman culture, a Greek rather than a Roman was preferred for pedagogue, and the institution of public schools, to which boys were sent at the age of 7 years, made the advantages of education more general. Under the empire the Greek literature was taught to the sons of the wealthy as carefully as the Latin, and the education was completed by rhetoricians, who in the time of Quintilian often received a salary from the public treasury. Athens, where there was an academy with 10 professors, was much frequented by the young Romans, and a school of high repute was founded in Constantinople by Constantine and reorganized by Theodosius the Younger. Girls were often carefully educated during the later period of the empire; and from about the close of the republic there appear to have been schools designed for them exclusively, where they were rarely visited by their fathers. Antoninus Pius (A. D. 138–161) was the first Roman monarch who established a school for orphans. The principal original sources for the history of education among the Romans are the writings of Cicero, Seneca, Pliny the Younger, and especially the *Institutiones Oratoriæ* of Quintilian.—At the time when the last vestiges of Roman supremacy were disappearing in the West, the genius of Mohammed raised an obscure people in a corner of Asia to sudden greatness. In the 7th century the Arabians overran Syria, Persia, Egypt, and the whole north-west of Africa, and in the next, Spain also. Though they had no native literature but poetry, and no science but a fanciful astronomy inherited from shepherds, and though they were at first as destructive to western learning as to Christianity, they yet soon discovered the value of the writings of the Greeks, especially of those on medicine, mathematics, and natural philosophy. Hippocrates and Galen, Euclid and Ptolemy, Aristotle and Theophrastus were translated into Arabic, and voluminously commented on; and in the 10th century, the darkest period of Christian literature, the Arabs had flourishing schools of learning from Bagdad to Cordova. Of their 17 universities, that of Cordova enjoyed the highest reputation, and is said to have possessed a library of 600,000 volumes. Grammar, the art of versifying, history, geography, astronomy and astrology, chemistry and alchemy, mathematics, and medicine were all studied, and in the last two departments the Arabians made important improvements on their Greek masters. An elementary school was attached to every mosque, in which reading and writing were taught, the pupils at the same time learning many poems by heart. At first, the sons of wealthy Arabs on reaching their 20th year were accustomed to go on a literary journey, visiting the most eminent savants who gave public lectures; but after the foundation of universities by the caliphs in the largest cities, these became the resort of those who desired a learned education. They were chiefly occupied with theology, jurisprudence, and speculative philosophy; and for the natural sciences there were special schools, while medicine was taught in hospitals. The professors and students dwelt in the same edifice, and usually there was but one eminent scholar connected as teacher with each university. In Spain the Saracens had their most brilliant career, covering the plains, the valleys, and the hillsides with palaces and costly dwellings in the light and graceful style of Moorish architecture, making poetry and the fine arts as well as scholarship flourish at the Moorish courts, and giving rich endowments to schools and universities, the advantages of which were open both to Christians and Moslems, and to the female sex as well as the male. Gerbert, afterward Pope Sylvester II., studied under the Spanish Arabs, and passing thence to France and Germany, is said to have revived in those countries arithmetic, music, and geometry, which had become unknown. Sharon Turner gives a list of Spanish-Arabian women who were noted for their erudition or their skill in poetry, oratory, philosophy, jurisprudence, or music.—The early Christians, unable to found separate schools for the education of their children, either instructed them at home or sent them to pagan schools. The names of Anthusa, Nonna, and Monica, the mothers and teachers of Chrysostom, Gregory Nazianzen, and Augustine, are memorials of the care with which Christian parents sought the intellectual and religious culture of their sons. The daughters also shared in the domestic lessons. Yet those who desired a learned education resorted to schools taught by pagans, the most flourishing of which in the 2d century was that of Alexandria, where a multitude of pagans, Jews, and Christians prosecuted their studies together. By the side of this ancient institution soon arose the Christian school of the catechists, said to have been founded by Pantænus in 181, in which Christian the-

ology assumed a regular and scientific form. It was designed especially to qualify young men to become preachers, but its course of study embraced mathematics, logic, rhetoric, physics, metaphysics, and ethics, as well as theology, and it continued in existence till near the 5th century. Its most eminent master was Origen, who, being exiled in 231 from Alexandria, soon after established a similar school in Cæsarea, in which St. Basil was educated. The school of Antioch produced Chrysostom and Theodore of Mopsuestia; and that of Edessa, called the Athens of Syria, and which was long the principal seat of oriental learning, attracted students from great distances, and is memorable especially for its part against St. Cyril in the Nestorian controversy. In all the Christian schools the Bible gradually became the principal text book, and the sciences were pursued only in their theological bearings. In the West there were till the 5th century pagan schools in the largest cities, as Carthage, Rome, Milan, Treves, Marseilles, and Lyons; and owing to the fewness of the Christian institutions, it was common for distinguished doctors of the church to assemble around them the young men who purposed entering the priesthood, and to instruct them by their conversation rather than by regular lessons. Early in the 5th century learning found a refuge in the monasteries which had been introduced in the East for purposes of solitude and contemplation, but in the West for quiet and union amid the disorders of society—as a centre and asylum for persons who wished to live, to discuss, and to exercise themselves together. The abbey founded at Tours by St. Martin, that of St. Victor founded by Cassianus at Marseilles, and that of Lerins founded by St. Honoratus and St. Caprais in one of the isles of Hyères, were philosophical schools of Christianity, in which the great questions of free will, predestination, grace, and original sin were warmly agitated, and in the last two of which the Pelagian opinions for half a century found their greatest nourishment and support. In the 6th and 7th centuries the schools were of 3 classes, the parochial, the cathedral or episcopal, and the cloistral or conventual. The first were in the house and under the care of a priest, were designed mainly to produce readers in the church, and the instruction in them rarely extended beyond the constant repetition of passages of Scripture; the second were of a higher grade, and usually under the direction of a bishop, were designed for the education of priests, though young noblemen were also received as pupils, and the canticles and formulas in use in religious worship were the chief subjects of study; the third received children who were devoted either to a religious or secular life, and taught them to read, to copy manuscripts, and to understand Latin. The cloistral schools were very numerous and for both sexes, most of those for females being under the discipline of St. Benedict. In the convent of Arles nearly 200 nuns were occupied in copying religious books, or sometimes the works of the ancients. The Irish monasteries at this time surpassed all others in maintaining the traditions of learning. The course of 7 sciences or liberal arts, divided into the trivium (grammar, dialectics, and rhetoric) and the quadrivium (arithmetic, geometry, astronomy, and music), was introduced in the 6th century, and defined in two jargon hexameters:

Gramm. loquitur; Dia. vera docet; Rhet. verba colorat; Mus. canit; Ar. numerat; Geo. ponderat; Ast. colit astra.

Yet learning was for the most part of a fantastic character and put to frivolous uses, and excepting the writings of Boëthius, the last utterance of classical culture, the principal productions and text books of the time were the arid compilations of Isidorus of Seville, Capella, and Cassiodorus. The 7th century, says Hallam, was the nadir of the human mind in Europe, and its movement in advance began with Charlemagne before the close of the next. This monarch invited to his court Alcuin from the cloisters of York, Clement from Ireland, and Theodulf from Germany, and reëstablished the palatial school, in which the sons of some of the nobility were educated with his own children, and which accompanied him wherever he went. It was called the palatine academy, and the members of it took names borrowed from sacred or profane history; thus Charlemagne was called David, Alcuin Horace, Angilbert Homer, and Gisla Lucia. In this school, and afterward in those of Tours and Fulda, the course of instruction embraced all the learning of the age. He also founded schools in every bishopric and monastery, in which reading, singing, computation, grammar, and the learning of psalms by heart were the exercises; and he instituted two schools at Soissons and Metz solely for instruction in church music, under the care of Italian masters. In two capitularies addressed by him to the religious preachers under his government, and to the abbé Bangulf, the head of a religious order, he insisted on a higher education for the priesthood, and the multiplication of correct copies of the Scriptures and of the Latin classics; and he bestowed fortune and honors on those monasteries and monks that excelled in the art of producing correct and beautiful copies. The study of Greek was partially revived, and it was made a condition of the endowment of the school at Osnabrück that there should always be clerks there skilled in that language. The emperor made an unsuccessful effort for the culture of the German language, causing a collection of the German popular songs to be made; yet his design was not seconded by the clergy, who esteemed German a barbarous tongue and relic of paganism which ought to be extirpated rather than cultivated. Less than a century after Charlemagne, King Alfred revived letters and schools in England, which had been almost extinguished by the Danish invasions, rich libraries having disappeared in the pillage of churches and convents. At his accession Wessex could not boast a single person able to translate a Latin book. He invited to his court

the most celebrated scholars, among whom were Plegmund, Werfrith, Ethelstan, Werwulf, Asser of St. David's, Grimbald of St. Omer, John Scotus Erigena, and John of Old Saxony, who left the monastery of Corbie for that of Ethelingey; he made translations with his own hand into Anglo-Saxon from Bede, Boëthius, and Orosius; established schools in different parts of his kingdom; and ordained that the children of every free man whose circumstances would allow it should acquire the arts of reading and writing, and that those designed for civil or ecclesiastical offices should be instructed in the Latin language. Yet his efforts in behalf of learning were as unfruitful after his death as those of Charlemagne had been in France, and were succeeded by the mental torpor of the 10th century, in which, it has been remarked, no heresies appeared. Yet Germany at that time possessed many learned and virtuous churchmen. In the school of Paderborn not only the 7 liberal arts were taught, but also Homer and Virgil were read, and the arts of painting and versifying practised; and in that of Fulda, the pupils of Hrabanus Maurus, himself the most accomplished pupil of Alcuin, gave instruction with zeal and care to noble youth. But as learning was chiefly contained in a dead language in all the countries of Europe, it hardly reached the mass of the people; the art of writing was so rare among laymen that it was called the clerical art; paper was excessively dear, and ink was so scarce even two centuries later that Petrarch only after great difficulty succeeded in finding some in Liège.—The rise of the scholastic philosophy and of the troubadour poetry, the institution of universities, and the return to a profound study of the Greek and Latin classics, were the literary steps during and after the 11th century which preceded the revival of learning in the 14th and 15th centuries. Intercourse with the flourishing Arabian academies of Spain should also be mentioned, since many scholars, following the example of Gerbert, studied in them, and imported the sciences thence into France and England. It was through the Arabic mind that western philosophers first became acquainted with the complete works of Aristotle, and learned to prefer his dialectics to those of Augustine; and some suppose that the literary culture of Provence proceeded from contact with Arabic poets beyond the Pyrénées. Knighthood demanded a moral and physical rather than intellectual culture. The sons of gentlemen who were trained to this profession were brought up in the castles of great lords, instructed in exercises of strength and activity and in the management of arms, accustomed to obedience and a courteous demeanor to their lord and lady, and trained to enthusiastic and romantic views of valor, honor, love, and munificence. Many of the noblest knights could neither read nor write. The Provençal literature and society, founded on the principles and customs of chivalry, were a remarkable example of culture without learning. It is surprising how little knowledge the troubadour poems presuppose; there is scarcely an allusion to history or mythology; and no references to foreign manners, or reminiscences of the sciences which had been taught in schools, are mingled with the simple effusions of sentiment. The fantastic solemnities styled courts of love and floral games, the serious discussion of ridiculous questions of metaphysical gallantry, the elaborately frivolous directions concerning the manners of either sex, are illustrations of a society without intellectual development, but highly and peculiarly disciplined in respect of the sentiments. From the 12th and 13th centuries, the era of the schoolmen, date 23 universities, including those of Paris, Montpellier, Oxford, Cambridge, Bologna, Salerno, Padua, Rome, Salamanca, and Lisbon. That of Bologna was especially famous for its revival of the civil law, and drew lawyers and students in large numbers to Lombardy from remote parts of Europe. Paris was unrivalled in the department of theology, and Montpellier in that of medicine. Roscellin and William of Champeaux were the first scholastic teachers who enjoyed brilliant success; and Abelard, the disciple of them both, attracted students by thousands to his lectures in Paris, fascinated the intellect of Christendom by a dialectic method, and awakened mankind to a sympathy with intellectual excellence. Though he was involved in a controversy with Saint Bernard, and though some of his opinions were condemned by an ecclesiastical council, and he was therefore ordered to be confined in a cloister, yet his scholars followed him to his hermitage in the wilderness, and enlarged his little oratory to a cosmopolitan and studious monastery called the Paraclete. One of his pupils was Peter Lombard, the author of the "Book of Sentences," which obtained the highest authority. The ingenious subtleties of scholasticism were promoted by the schools of the mendicant orders, and the two greatest masters of the method, the champions of distinct systems, were the Dominican Thomas Aquinas and the Franciscan Duns Scotus. The most determined opponents of the scholastics were the mystics, the promoters of piety rather than learning, the principal representatives of whom were St. Bernard of Clairvaux, Thomas à Kempis, Tauler, and in his later years Gerson. The university students, notwithstanding the enthusiasm and attainments of some of them, were often subjects of satire. It was complained that they frequented eating and dancing houses, and strolled through the streets by night shouting and singing; that they went from university to university, not to increase their knowledge, but to be able to boast that they had studied at Paris, Bologna, or Pavia; and that they surrounded themselves with large libraries and paraded doctors' caps in order to win admiration for learning which they did not possess. The minor schools were said often to be badly conducted; the master was not sufficiently under the surveillance of

the bishop, and might be one of the numerous secular ecclesiastics, *scholastici*, *scholares vagantes*, *bacchantes*, or *goliardi*, who traversed Europe as adventurers, becoming curates, teachers, or sorcerers, according to occasion, foretelling eclipses, selling calendars and false relics, and defrauding the people in manifold ways. It was not uncommon for children to imitate the older students, passing from school to school in groups, begging, stealing, and singing before houses. Yet the rod played a prominent part in schools, and a vignette found in most of the mediæval classical books represents a master holding it in hand. A festival of the rod was one of the holidays, when the boys and girls went together to the nearest forest for a bundle of birchen twigs, and returned singing a chant relative to the use which the master would make of them. During the period preceding the revival of learning female education declined. Only a few schools were maintained in the large cities for the instruction of girls in reading, and the inmates of convents were taught hardly more than to repeat their prayers and to practise embroidery and other needlework. A writer of the 13th century defines the proper education of woman as "knowing how to pray to God, to love man, to knit, and to sew." From the time when the ill-fated Heloise taught the sciences and the Greek and Latin classics to her nuns, till the latter part of the 15th century, western Europe furnishes no female name renowned for learning except that of Christina of Pisa.—When the Byzantine empire approached its fall, the Greek scholars who had there preserved some acquaintance with ancient learning took refuge in Italy, where the love of letters had been already awakened by the genius of Dante, Petrarch, and Boccaccio, and where industrious scholars under the patronage of princes were devoting their lives to the recovery of manuscripts and the revival of philology. Among those who at this period of the renaissance specially distinguished themselves as teachers, the most eminent was Victorino Rambaldoni (born in 1378), who conducted schools successively at Padua, Venice, and Mantua, attracting pupils from France, Germany, and Greece, but admitting only those of distinguished talents. He wrote nothing, but his sagacity and success in forming the character of students and in producing a harmonious and complete development made his name famous for centuries as an instructor. The right study of the classics he believed to be amply sufficient for all the purposes of education. Among Italian writers on education in the 15th century were Vergeri, Poggio Bracciolini, Vegi, and Æneas Sylvius, afterward Pope Pius II. From Italy the more profound study of classical authors passed to the other countries of Europe, and a contest was long maintained between the scholastic and the anti-scholastic studies; between the Aristotelians, who included the most learned ecclesiastics, and the Platonists, to whom were attached most of the cultivators of polite literature. Agricola in Germany, Valla in Italy, and above all Ramus in France, wrote against scholasticism. It was assailed by the reformers and defended by the Jesuits, and is still in honor in some of the Spanish universities. Purbach, Regiomontanus, and Nicholas Casanus were the first to promote the study of the higher mathematics. Nicholas de Clemengis and Gregorius Tifernas revived the classical taste in France, Vitelli and Coilet in England, Lebrixa in Spain, and Reuchlin in Germany. The pious "Brethren of the Common Life," whose first school was founded by Gerard de Groot at Deventer in 1340, also exerted a wide influence. Their schools were extended throughout the Netherlands and Germany, were distinguished alike for piety and solid acquirements, and attracted students even from Italy. From them proceeded Thomas à Kempis, and many who were afterward celebrated as reformers. In 1483 a severe and almost barbarous discipline was ordained in the college of Montaigu, combining labor, fasting, and pitiless punishments. Yet among the students who in a few years proceeded from this school were Erasmus, Loyola, and Calvin. Erasmus, with polished jests admirable for their *esprit* and learning, seemed to revive the ancient Attic wit, and exerted a refreshing influence on letters. The golden age of the literature of Belgium was that of Albert and Isabella in the first quarter of the 17th century, in which the triumph of the renaissance was completed. The university of Louvain was the centre of a wide intellectual culture, and the *alma mater* of many celebrities. Its European reputation increased till in 1570 it had 8,000 students.—Education and the doctrines concerning it played an important part in the movements of the Protestant reformers, and also in the reaction in favor of the papacy under the Jesuits. The revival of intellectual culture among the people was associated in the mind of Luther with religious reform, and in 1528 with the aid of Melanchthon he drew up the plan of studies which was followed in the Protestant common schools of Germany till the close of the century. The first class learned to read, to repeat from memory a few distichs, to write, and to sing, and began the study of Latin. The second class studied Latin, grammar, and music for an hour daily, read and interpreted the fables of Æsop, the *pædologia* of Mosellanus, and the colloquies of Erasmus, and committed to memory parts of Terence and Plautus, and some of the psalms and other portions of Scripture. A Latin and a German sentence were repeated to the students on their departure at night, which they were to know by heart on the following day. The third class advanced to the Latin poets, and to exercises in dialectics and rhetoric, and were required to speak in Latin, and to write an exercise in that language weekly. Luther also assailed the Aristotelianism and scholastic methods which prevailed in the universities, and recommended the establishment of libraries in every town. Education was in like manner encouraged by Zwin-

gli and Calvin, the latter of whom caused the erection of a splendid edifice for the gymnasium of Geneva, to which 8 distinguished professors of Hebrew, Greek, philosophy, and theology were invited. About this time the gymnasium of Strasbourg under Johann Sturm became the most flourishing of the age, and in 1578 it had more than 1,000 students, 300 of whom were of noble or princely birth. Its best influence was in improving the taste, for Sturm taught the classical languages for their own merits, and not as auxiliaries to theology. He therefore banished from the school all writings in barbarous Latin, and urged children from the age of 7 years to speak with each other and their professors in choice Ciceronian phrases. He made them commit to memory select passages from the classics as they were translated to them, before the details of grammar had been mastered. Sturm was the friend and correspondent of Roger Ascham of England, one of the most learned men of the age, and the author of a treatise on the "Schoolmaster." The school of Trotzendorf, at Goldberg, was distinguished for the organization of its discipline, the forms of which were borrowed from the old Roman republic. He was the perpetual dictator, and beneath him were a censor, 2 consuls, and a senate of the 12 most advanced pupils. Every grave question was discussed before this senate, and was decided by it. The ancient crowns were revived for prizes, the best orator being rewarded in the manner of a victor at the Olympic games. Bugenhagen at Hamburg, Spalatin at Altenburg, Neander at Nordhausen, and Heyden at Nuremberg, were also among the most successful Protestant teachers of this period.—The Protestants having awakened a zeal for learning, the Jesuits determined to avail themselves of this zeal in the interest of the Catholic church, and to combat the reformation with its own weapon. They cultivated to the highest possible degree all departments of science, and employed the authority of learning in favor of the pontifical power. The principle of their method was to train the memory, the imagination, and the reasoning faculty, but to check all discursive mental habits. Latin and logic furnished most of the exercises by which the sentiments and tenets of Catholicism were instilled into the minds of youth. Of the classical Latin authors only Cicero and Virgil were used, the other Latin text books being mediæval writers. Greek was taught only from the works of Chrysostom and other Christian fathers. Philosophy formed a part of the higher course, and was taught from Aristotle as interpreted by Aquinas. The polished and pleasing exterior of masters and students, the kindness apparent in the treatment of young persons, the tender care bestowed upon sick pupils, the pompous occasional celebrations, and the theatrical performances which were often made a school exercise, all contributed to the extraordinary success of the Jesuits as teachers. From Cologne, Ingolstadt, and Vienna, they spread between 1550 and 1560 throughout Germany. Opposed in France by the Sorbonne, the university, and the parliaments, they did not establish their first school in Paris till 1665, but in 1750 they had won from the ancient Benedictines their pedagogic laurels, and possessed in France 669 schools, which were attended by the children of the princes and nobles. Yet the education of females was much less cared for by them than by their opponents the Jansenists. The girls belonging to the upper classes connected with the society were educated religiously rather than learnedly in the numerous houses of the sisters of St. Ursula, or by the nuns of St. Angelica or St. Elizabeth.—Between the latter part of the 17th and the close of the 18th century, 4 distinct theories and methods of the pedagogic art arose, which are usually named the pietistic school, the humanistic school, the philanthropic school, and the eclectic school. Jansenius in France, the Wesleys in England, and especially Spener and Francke in Germany, were the first representatives of the pietistic tendency. The writings of Fénélon, the author of "Telemachus" and of a treatise on the education of girls, which still remains a standard work in France, exerted perhaps a similar influence. Spener was the teacher of Francke, who established a school at Halle for children of both sexes, and another for teachers, on the principle that religious and moral instruction should be made more prominent than intellectual acquirements, that the end of education should be a living knowledge of God and of pure Christianity. It was succeeded by similar schools in many other cities, and one of its early graduates was Count Zinzendorf. In Greek the New Testament was the only text book. Hebrew was one of the studies of the regular course, and a change of heart was declared essential to successful scholarship. Among the collaborators of Francke were Rambach, Freyer, Hoffmann, Büsching, and Steinmetz. The humanistic school maintained the principle that the ancient languages and literature, especially the Greek and Latin (which were termed the humanities), should be the foundation of education, and should be exclusively studied till the pupil went to the university. Among the more eminent humanists were Cellarius, Gesner, Ernesti, Morus, Reiske, Hermann, Schaefer, Schneider, Heyne, Wolf, Voss, Creuzer, Bockh, and Jacobs, many of whom prepared admirable editions of the classics and works on classical archæology; and their principles have been most nearly followed in the schools of Saxony and the Netherlands, in the seminary of St. Thomas in Leipsic, and in the gymnasium of Strasbourg. New ideas upon education were developed by Comenius, Locke, and Jean Jacques Rousseau. Some of the educational works of Comenius were translated into several languages, and his *Orbis Pictus* long remained a popular household book, and the model of picture books. His aim was to make education more simple and conformable to nature, to have more regard for diversities of character, to teach nothing which could not be

understood by the pupil, and to render the process of learning easy and agreeable. Locke applied to education the principles of the Baconian philosophy by which a scientific realism was substituted for the old logical verbalism, and things rather than books made the sources of knowledge, and urged the union of a due regard to positive and practical science with the culture of the intellect through the medium of language. The *Émile* of Rousseau contains a system of education founded on the ideas but not the experience of its author, and presents an ideal and joyous view of domestic culture most strongly in contrast with the circumstances of his own life. The early education of the child is, according to him, of the greatest importance, and the charge of it can properly belong only to the mother and the father. In the long procession of things to be learned, nothing appears till the student is prepared to grasp it without difficulty, and the attainments in knowledge come almost unconsciously by a series of easy steps. The child, too, should be educated not for a trade or profession, but for the common and absolute state of man; should not therefore subject himself to any thraldom of habit, but be independent of every thing about him, and master of himself. Shielded from the corruptions of society and the trammels of conventionalism, and left open to the influences of nature and of conscience, the character should perfect itself intellectually, socially, and morally. Parents were allured to study a system which seemed to remove all trouble, labor, and care from the concerns of life. Education was to become an amusement, and man a reasonable creature, without annoyance, without perverted inclinations, without even a futile effort. To realize the theories of Rousseau was the task of Basedow, and he succeeded in effecting great changes in the nature of education in Germany. He announced an immense institution to be founded at Dessau, and to be called the *Philanthropinum*, in which the child was to remain till he was a man and a citizen. The *Elementarwerk*, in which he exhibited his plan, received subscriptions from princes, magistrates, ministers of state, and the most distinguished learned men of Germany and Switzerland, all entertaining an exaggerated enthusiasm for the new human culture, in which nature was to take the place of discipline. An ideal was conceived in striking contrast with the reigning severity of masters, primness of pupils, perruques and swords of little boys, and hoop petticoats of little girls. The *Philanthropinum* was established in 1774, under the care of Basedow and Wolke, but declined after a momentary splendor. It was continued with better success by Simon and Schweighäuser, and similar institutions were founded at various places in Germany, only one of which, at Schnepfenthal in Gotha, still continues. Under the name of eclectics are classed those who were the disciples of no exclusive school, but from truly philanthropic motives sought to instruct classes hitherto neglected. Such was the origin of the efforts for the instruction of deaf mutes by Heinicke, Braidwood, the abbé de l'Épée, and Sicard; the instruction of the blind by Valentin Haüy, Klein, and Lenné; the institution of Sunday schools by Robert Raikes, Oberlin, and others; the organization of reformatories by Odescalchi and Tata Giovanni in Rome, and by the philanthropic society in London; and many of the special schools of commerce, agriculture, mines, the arts of design, and other departments.—In Germany since the latter part of the last century the principles of education have been actively discussed, the most prominent writers on the subject being Sulzer, Miller, Weisse, Ehlers, Büsch, Feder, Resewitz, Gurlitt, Funk, Roetger, Heusinger, Niemeyer, Schwartz, and Bencke. But the man who for the last hundred years has exerted the greatest influence on education is the Swiss Pestalozzi. According to the principles developed by him in various writings, education must begin early, under the discipline of home and the direction of parental wisdom and power. It must proceed according to the laws of nature, slowly and uninterruptedly, the teacher exciting the child to activity and rendering him but a limited amount of assistance. Individuality must be held sacred, and carefully studied and encouraged. Verbal teaching is futile unless it be implanted on previous mental experiences and verified by the senses. A development by merely mental operations, which the Socratic method favors, is vain and harmful, for the child can only utter a judgment concerning an object when he has examined it experimentally, and learned precisely to distinguish its qualities and attributes by words. Form, number, and language are the elements of knowledge, the principles by which the mind must be developed; and a thorough acquaintance with them in the various departments of learning constitutes an education. Therefore mental arithmetic, geometry, and the arts of drawing and modelling objects of beauty, are as important exercises as the study of languages. The school should be a place of liveliness and activity, and the scholar should have opportunity to exercise and reveal his power. The system of Pestalozzi has been adopted in the Prussian schools with slight modifications, and has exerted a greater influence than any other on teachers in England, America, and the north of Europe. His system was modified by Fellenberg in his institution at Hofwyl, by Jacotot in the university of Louvain, and by Felbiger, bishop of Sagan, in the schools which he organized. There were combined at Hofwyl an agricultural institute, theoretical and practical, a rural school for the poor, a superior school for the sons of the nobility, an intermediate school for those of the middle classes, and a normal school for the instruction of the teachers of the canton. The system of Fellenberg varied from that of Pestalozzi only by communicating more practical and positive knowledge. The method of Jacotot, which has

been generally adopted in Belgium, gives greater exercise to the faculty of memory; he required his pupils to recite by heart all their lessons, whether in the languages or the sciences. The method of Sagan, so named from the see of its author, is a combination of the methods of Basedow and Pestalozzi, was propagated in Bohemia by command of Maria Theresa, and was in vogue throughout Austria till 1842. It regarded education only from a utilitarian point of view, and aimed to amuse the scholar while instructing him, and to make the lessons as clear as possible, passing to the unknown from the known. It rapidly traversed numerous branches of study. Joseph Lancaster (died in 1839), a member of the society of Friends in England, was the founder of the monitorial system, by which the most intelligent pupils in a school were required to teach their fellows what they had learned in advance of them. This plan doubtless developed the intellect of the monitor, and was at one time adopted in many schools in large towns in England and America, but has been abandoned from the fact that the incomplete and confused knowledge of the premature teachers often made their instructions rather akin to error than to truth.—Germany, with most of the other continental countries, England, and the United States present three different methods of administering the national elementary education. The Prussian educational system is purely governmental, emanating solely from a minister of instruction immediately dependent on the crown. The universities, the gymnasia, and the primary schools are all under laws and regulations which proceed respectively from the crown, from the provincial government, and from the communes. Every child in the kingdom is obliged under pains and penalties to attend school at least from the age of 7 to that of 14, and the result is that the Prussian people are efficiently educated throughout the entire community, and that the universities send forth a large body of highly educated men. Yet with their vast and powerful machinery for popular instruction, the Prussians have not taken a leading part in civilization, and the reason is stated by Horace Mann to be, that when the children once leave school they have few opportunities of applying the knowledge or exercising the faculties which have been acquired and developed there. The national education of all the German states closely resembles that of Prussia. The universities, colleges, and primary schools of France (the latter of which were organized in 1833 under the administration of Guizot, from reports on the German system of popular education made by Cousin), are in like manner established and directed by governmental authority. Permission is however given to any teacher under certain conditions to open a private school; and denominational schools may be registered on the government list of educational institutions. But in England no schools (except those connected with pauper, naval, military, and penal establishments) are initiated by the civil government, or to any considerable extent managed by it. The education of the people is under the care of the established church and of the other religious organizations, and the government comes to their aid by bestowing grants on certain conditions when its assistance is required. The system is entirely different in the United States, where, though the state governments take the initiative, they only go so far as to ordain that schools of a certain character must exist among a given population. All the questions concerning the buildings, teachers, and methods of instruction are determined by the people in their capacity of free citizens. The government provides for education, but makes the people its agent in accomplishing the provision. Consequently, there is much diversity in the educational condition of different parts of the country, the school system being generally most complete in the most compactly settled states, especially those of New England. The efforts of Henry Barnard, Horace Mann, David P. Page, Alonzo Potter, Barnas Sears, and others, during the last 20 years, have been influential in introducing large and well-directed measures and plans for the improvement of public education in America.—Among the most valuable treatises on the subject are: Schwarz, *Erziehungslehre* (Leipsic, 1829); Cramer, *Geschichte der Erziehung und des Unterrichts in welthistorischer Entwickelung* (Leipsic, 1832–'38); Von Raumer, *Geschichte der Pädagogik seit dem Wiederaufblühen classischer Studien* (Stuttgart, 1843–'52); Fritz, *Esquisse d'un système complet d'instruction et d'éducation* (Strasbourg, 1841–'43); Théry, *Histoire de l'éducation en France* (Paris, 1858); educational reports of the Canadian school system, and of the superintendents and boards of education of the different states of the American Union; Henry Barnard, "National Education in Europe" (Hartford, 1854), "Journal of Education" (6 vols., Hartford, 1856–'59), also educational tracts, and reports on the public schools of Connecticut and Rhode Island; and Horace Mann, "Annual Reports of the Massachusetts Board of Education" (Boston, 1837–'48), and "Lectures on Education" (Boston, 1855).—The educational systems and statistics of different states and countries are given under their respective titles.
